This paper describes the activities undertaken in "Meeting of Minds", a research project designed to investigate the common concepts and different approaches employed by the major schools of Urban Morphology, (FAPEMIG- PPM/ 2011-2013) which was accomplished in 2013. The incentive to develop this research is mainly due to teaching activity which has been based on the principles of the two traditional schools of Urban Morphology. These were previously presented on separate courses containing a practical assimilation of content over several years. In more recent years we have chosen to offer a course in condensed form containing the concepts of the two schools which have also been further explored in practical studies.

Another stimulus for this research was that it emerged as a result of suggestions made by Whitehand (2001) to those he encouraged in the development of studies designed to generate common concepts within the two schools. On the one hand, the main objective of the research comes from the need to disseminate the didactic concepts necessary for application in national Urban Morphology post graduate programs. On the other, the following specific objectives have

been identified: discuss common concepts in the various schools of urban morphology; identify the characteristics of each school; establish contemporary morphological thought.

The development of the research

The research was divided into two stages, the first being related to obtaining data on the English School of Urban Morphology and the second, to data collection on the Italian School. The first stage of the research began with a literature search on the main representatives of the English School in order to identify lines of investigation and conceptual currents. The literature in English was scanned and has been made available on the ISUF website and data was also obtained from interviews with key representatives, in addition to material obtained from books and periodicals. The data acquisition on the English School became a simple task and it was thus completed within the planned stage.

In contrast, the collection of data on the Italian School was rather more difficult. Some information is available on the ISUF website, but almost every article makes references to the professional architectural history of its founder, Saverio Muratori. (Marretto, 2012). Most of the data contains the work of Muratori's disciples who recorded, reinterpreted their classes with him and published a few books, almost all in Italian and now unavailable and out of print. Possible alternatives led us to interpret the projects planned by Muratori and assess possible concepts employed in his style and practices. Another strategy was to seek out publications written by Muratori's followers with the aim of establishing common concepts.

We opted to follow both alternatives, but the following factors have adversely influenced the development of the research project. Almost all literature is in Italian and as publications are not digitalised we were dependent on our Italian colleagues sending copies of the work in question, as well as, the availability of Italian teachers to fulfil such requests. Furthermore, there is only one publication in English on the method and in order to gain a full understanding it became necessary to translate and interpret the whole book (*Interpreting Basic Building* by Cannigia Gianfranco and Gian Luigi Maffei) (2001). Moreover, the concepts are not easily assimilated and it was necessary to promote seminars that provided an understanding of the work by reading the chapters and discussing the subject amongst members of the Laboratory of Landscape / EAUFMG. However, the main concepts were finally identified, analyzed, evaluated and compared, as the following part of the article will demonstrate.

The conceptual foundations of the traditional school of urban morphology

The conceptual foundations of the instrument have been addressed differently by followers. Analysis has been distinguished by greater emphasis on some elements of urban form rather than others, the differing focuses giving rise to the contrasting schools of urban morphology.

The English school of urban morphology structures its conceptual basis on the formulation of historicity which is the ability of the urban landscape to present the visible results of the morphological periods. Historicity is thus viewed as an attribute of the landscape that reflects the diversity and strength of its social historical and cultural content. Therefore, the overlap of new and old buildings is viewed as being the normal consequence of population growth, which has resulted in the adaptation of existing structures to meet current needs. Also apparent is the transformation that these structures have undergone in order to render them suitable for contemporary uses.

For these reasons, the evidence of historicity in the urban landscape suggests identification of these processes of historical interest generally, and such phenomena may be viewed as the ensembles of cultural and social needs during successive, more or less distinct cultural periods (M.P.G. Conzen, 2004). The morphological processes result from the development of the plan and its economic, cultural and functional determinants. The study of the successive plans of a

city and the oldest evidence of historical morphological phases show the city's development in terms of growth and inner transformation over time.

This study, together with analysis of the plans, aims to contribute to increasing the perception of the three morphological complexes, the road system, the standard division of plots and the built up area, which make up the urban landscape. These categories are closely related to individual buildings and units of land use, are found anywhere in the urban landscape and serve to accommodate one or another element of the urban plan. (Conzen, 1969)

In contrast, the Italian school is structured on the belief that there is a way to build homes that is intrinsic to a particular people, manifested in its culture at a given point in time. This particular way is viewed as a kind of gift already rooted in people's minds as a prototype inherited by every inhabitant of the group that proposes to build a house. This reproductive capacity of the people, to build prototypes without barriers and judgment, is referred to as spontaneous consciousness. Therefore, this consciousness, together with, human interactions with nature, structures the fundamental concept of the Italian school. (Caniggia ET Maffei, 2001).

As a methodological alternative the built type is considered "synthesis a priori" and the object of the morphogenetic historical research of the existing urban fabric. A typological study consists of the selection of a basic type which is in turn compared to other existing types. As such, it is possible to determine the appropriate level of specificity and thus establish the types of morphological distinction. With the structure of types and their respective classification established, the processes of evolution of urban areas can be traced leading to an understanding of the human environment. These are, in summary, the basic conceptual theories of the two schools of urban morphology. Their similarities and differences are discussed below.

Similarities and differences between the traditional schools of urban morphology

The common basis of the two schools lies in the researched object - the urban form and its transformations. Both schools study the transformation of the urban fabric and describe the transformative processes that occur over time, as well as, manifesting a shared notion of the urban form's formative and transformative process (Pereira Costa et al, 2013). Another commonality between the two is the realization that urban forms reflect the social, political and economic actions of agents within society.

The actions of economic forces often occurs through land speculation and, as noted by Rossi in 1980, through the implementation of urban plans that are determined by economic forces. The author concludes that the study of these actions is facilitated by the abundance of material in the capitalist city, usually manifest in plans. Both founders of the schools agree with such contentions. Thus for Conzen, (1969) the urban plan of the city is a reflection of the needs of its inhabitants and how the economic order settles at different times to meet such demands. According to the author, a reading of the urban plan gives us above all, an understanding of the different legal economic and political conditions prevailing in each period. These perceptions are important primarily because they allow the researcher to identify, through the decoding of planning regulations, the legal restrictions, political and economic data prevailing in each period.

Muratori, for his part, considers urbanism as a set of architectural products that renew and adapt according to the needs of society and thus the architectural objects are a physical reflection of these needs. For Muratori (1959), cities are great architectural compositions; they thus become a theoretical and methodological instrument of great importance. He comments that for urbanism, the essential fact is the urban organism and the character of the cities. The latter can be taken as a basis for the original sense of the urban development plan over time. It can also be viewed as a manifestation of the role of urban structures and buildings in civic and social life, moral environment, traditions and history. Pardo (1980).

The commitment to the preservation of the cultural bases of their respective countries, demonstrated by the two teachers throughout their academic careers, is also another important common point between the two schools. (Moudon, 1997). However there are differences regarding the approach of these schools which can be attributed to the academic background of the two founders: Geography and Architecture.

Differences

If the main object and beliefs share a common basis, the differences are mainly due to the methods of approach, characterized largely by the academic background of the two founders and their respective nationalities. The method developed by the German geographer M.R.G.Conzen, (Whitehand, 1981), the most eminent representative of the English school, is often referred to as a tripartite vision. In this, the urban landscape is seen as a composite of forms which belong to the three systematic categories: the urban plan; the urban fabric and the pattern of use and land occupation. In any urban landscape these categories are closely associated.

According to Conzen, the plot is the essential element in the urban plan as it represents the functional aspect of the city which expresses the logic of the genesis of a geographical settlement. The author notes that, even if changes related to the road system and land subdivision occur in the form of cities, the plot demonstrates the ability to align towards the streets and their extensions, adapting and maintaining its characteristics in the face of urban transformation over the centuries.

Moreover, the process of land subdivision in cities reflects the economic and social order of the inhabitants and transformation throughout time. The correct combination of each element is the result of land conditions and it is established by morphological homogeneity over all existing area units. This represents a planning unit which is unique and distinct from any other existing in the surrounding neighbourhood. Different regions combine their hierarchical system to form the whole of the urban landscape and it is vital to ensure the permanence of urban landscapes as important cultural assets.

The practices and articles written by Conzen led to the conclusion that the investigative line found in the English Morphology School is a result of a geographical background based on concepts developed at the Berlin School of Geography before the Second World War (Whitehand, 1981). The concepts learned by Conzen, during his academic training at the school, were applied in his daily practice in England after immigration in 1933.

The English Morphology School sees the urban form as a structure settled on a natural site. The method takes into consideration the global view of the site in order to analyse the town plan and its components, the road system, the standard division of plots and the built area. The method takes a broad view by going into a detailed analysis of the land occupation.

Conversely, the vision of the Italian school is structured in reverse. The school sees the city as a living organism, in constant transformation that is structured by built forms. Muratori conceives the morphological analysis based on an architectural scale and by focusing on the study of the building type - the prototype of the residential building can be viewed as a synthesis of a collective history defined from the observation and interpretation of the built environment. The architectural type is a construction, a built organism, which springs from the mind of an individual and thus expresses an experience that is repeated various times in order to meet the typical requirements of society. In a way, it absorbs and reflects all essential human aspects.

Analysis of the morphological type starts with the selection of the building type which resembles a cell, and as such, forms groups of constructed units. These clusters are established around the nucleus connected by what is known as a matrix route. The buildings are constructed parallel to the matrix route and this consequently leads to subsequent occupation within the area. Another further development is a pathway which follows a perpendicular trajectory in relation to the matrix route and thus gives rise to the construction of other connecting routes.

Other buildings are constructed far apart and settled parallel to the line of the matrix route. In order to reach these new buildings, new routes are constructed in parallel to the main axis and the block becomes consolidated. Thus, the scale of research widens gradually due to the establishment of blocks of similar building types, which in turn structure the urban fabric. The city then becomes a mosaic.

The formation of the sets of urban fabric, receives from the Italian school of urban morphology, a comprehensive and detailed conceptualization. Furthermore, the territory is viewed as being strictly and directly related to the spontaneous consciousness of a human being's feeling of belonging to a certain place at a given time. This assumption leads to the concept of a cultural area whose limits are different from other bordering geographical territories due to the fact that they manifest specific cultural characteristics.

In summary, the analysis of these concepts from both schools reveals fundamental differences between them concerning comprehensiveness and applicability. This is because one is structured from a universal and the other a regional perspective, being that, the first structure has a notion of territory based on Human Geography while the latter Italian, is based on regional architectural interpretations. (Pereira Costa, 2013).

The geographical concept identifies the formation of routes as structural elements of communication and consequently, input vectors in the formation of urban centres, as such, they are considered to derive from a universal concept. In contrast, for the Italian school routes appear due to the human sense of belonging to a specific place and time, thus the concept is restricted to Italian culture and to the specificity of a given territory. (Strappa et al, 2003).

The notion of territorial pre-existence has permeated the studies of the founding fathers of the two schools. However, it is perhaps significant to mention that they never knew of the existence of the other or had knowledge of each other's respective studies which were then in development. According to Samuels (2002), they were only a generation apart, came from different cultural and professional worlds and yet had similar techniques when arriving at conceptions of the evolution of urban form.

Synchronicity between themes and independent approaches

Reports recognize the presence of similarities between scientific research in different areas of knowledge which interface chronologically and linearly and yet have no physical relationship with one another, given the great distance of time, culture and other circumstances that separate them. This phenomenon is named by Jung (1980) as synchronicity and corresponds to a coincidence in which two or more events, without causal relationship, manifest themselves simultaneously and with the same meaning for the human psyche. This can take the form of an external event and is independent of time and place. Basically synchronicity is defined as coincidence and significance, which in turn, requires the existence of an archetype. Archetypes are psychotic factors which have the power to transgress because they are not unique to the psychic sphere. They can also occur in non-psychic circumstances thus constituting the equivalence between the external physical and psychic process. Jung (1980)

This phenomenon was also observed by Thomas Kuhn (2007) who thought that time and space should be considered from the point of view of synchronicities, due to the fact that, objects of research always show aggregated results for scientific ends. According to Kuhn, the advance of science is not cumulative or linear and usually occurs, in contrast, in discontinuous ways characterised by major rupture or "scientific revolution", such historical watersheds being marked as a time of paradigm change. Paradigms are defined by Kuhn as a particular way of looking at the world, which articulates in a coherent manner, problems, concepts, research methods suitable for specific communities according to certain periods of time.

Jung contends that synchronicity occurs in more perceptive and attentive minds that somehow are the catalysts and in a certain way, the guardians responsible for the cultural heritage of the social group. There is no evidence to affirm whether this phenomenon also

occurred in other areas of knowledge of the period, however it can be recognized in the field of Human Geography and Architecture and Urbanism and especially in Urban Morphology. In the latter, therefore, the title custodian of knowledge, can be held by certain morphological elements - the plot for the geographer and the house for the architect.

The selection of the plot and the study of its transformation is due to the fact that it is the smallest unit into which human beings divide the land and establish the urban form. In addition, the plot is the place where human beings individually establish themselves and define their individual limits in the collective place. This selection is of the utmost importance because to Conzen, it is on the plot, the smallest divisible parcel and one which houses the distribution functions of the urban structure, that the whole process of transformation will be more clearly manifest throughout time. Likewise, in the architectural field of knowledge, Muratori highlights the basic type, the residential space and the urban element that is found abundantly in cities. For him, the house is an extension of the human body, which is part of a larger organism - the city.

The events that succeeded World War II demonstrate the effectiveness of the two choices - both being pioneering and catalytic, as well as, fundamental in deciding which morphological elements should be preserved. Furthermore they demonstrate how the two morphological elements, the plot and the house, are chosen to maintain the memory and preservation of morphological knowledge, for without these we would have no discussion here in 2014.

Conclusions

Presented here are the results of the research on Urban Morphology conducted by the Laboratory of Landscape/ UFMG. The main goal of the project was to establish the methodological knowledge generated by both schools in order to facilitate the development of a larger, interdisciplinary approach to the urban morphology of contemporary cities. Thus, it can be concluded that the urban form is constantly transformed either by the individual or by collective decisions taken throughout history. These decisions reflect the cultural aspects of their era and are in turn objectified in the formation of the urban landscape, setting in motion the evolutionary process, which is the object of analysis in urban morphology. As transformation is a natural process in the evolution of urban landscapes so its permanence must be identified, analyzed and elected for the preservation of cultural and environmental value. Thus, permanencies are also the result of human decisions and are aspects that significantly contribute to the unique quality of the urban landscape.

Therefore, in order to understand the process which results in the construction of a building or a city, it is necessary to investigate the latter's formation and transformation. The different forms of transformation were described by the founders of the two schools on different scales and levels of abstraction. The Italian school of urban morphology, for example, sees the typological process in relation to the transformation of the building type, which leads to the classification of buildings or other elements. In contrast, the English school sees, in the evolution from a morphological or historical period to the subsequent era, the long-term transformation of the form as constituting a complete range of transmitted features a specific culture can generate.

Taking into account a broader view of both sides of the analogy, it appears that there are significant similarities between the typological process and the theory of evolution of urban landscapes. Both concepts can be used for the benefit of contemporary research approaches to the built environment. Conducting a comparative study of the different types of approach have proven fruitful in comprehending the development of the complex structure of contemporary cities. In this sense the differences between schools are critically important because they can represent, not only differences in approaches, but also provide the complementary tools necessary for enhancing overall methods and results in Urban Morphology.

Urban analysis techniques and role of morphology in post crisis urban design: the case of Rubattino and Ortica districts in Milan

Ioanni Delsante, Nadia Bertolino

School of Art, Design and Architecture, University of Huddersfield
School of Architecture, The University of Sheffield. Email: i.delsante@hud.ac.uk,
n.bertolino@sheffield.ac.uk

Abstract. *Urban spaces and towns are facing different and contradictory dynamics, between “endless” expansion and “shrinking” trends. Post financial crisis urban renovation also deals with different practices, between real estate development and temporary use entailing reappropriation of urban areas. It is nowadays almost impossible, at least in Europe, to realize major town plans similar to those carried out in the past decades, but new forms of urban renovation, much more complex and fragmented, or temporary and low cost, are now spreading. They allow the participation of different actors (public / private partnerships), flexible timing and spatial organization, with the not secondary goal of reusing urban territories and buildings. The aim of renovation projects is more and more focused on social issues and challenges, for example in terms of quality of life and health, also by means of innovative housing programs, and sustainable layouts over the years: which will be the effects of this “programmatic” architecture on urban morphology? The completion of elaborate programmes requires deep and integrated urban analysis, based on a “reading of the town” through multiple and complementary methodologies (i.e. considering the town as combination of layers, the town seen as an archipelago or a “town within the town”). Urban morphology plays an important role in defining urban strategies, especially within fragmented or superimposed layouts. Rubattino and Ortica districts in Milan represent a meaningful case study for research and design: it could be described as a multi-layered and multi-composed scenario, considering its various parts and their “complementary”, “separated” and even “contradictory” status, as opposed to a homogeneous and uniform one.*

Key Words: *post crisis urban design, programmatic architecture, town as combination of layers, town as ‘archipelago’, Rubattino and Ortica districts in Milan*

Contemporary situation of urban settlements

Towns and urban territories have to deal simultaneously with contradictory dynamics: on the one hand “expansion”, that is mainly linked to urbanization trends at a global level (Bugatti and Shiling, 2011), and characterizes the *megapolis* of developing countries (i.e. Asia, South America), or the sub-urbs of urban territories (Garcia Vázquez, 2011).

The meaning of “town” (Rossi, 1982) itself is changing (Cacciari, 2003) as the existing habits, rules and procedures contributed to create an uncontrolled urban effect and to the “*eradication*” of planning activities. The results are evident in terms of urban “sprawl” (Ingersoll, 2006) that could represent also a loss of meaning for human settlement. “Greenfields” are economically attractive for the real estate industry, so that urban settlements too often expand with no relationship with landscape and environmental sustainability.

On the other hand, urban degrowth and town shrinking are already occurring, mainly due to postindustrialization and post financial crisis effects that are affecting specific territories (i.e. Detroit in Usa). Sometimes these events create large urban “vacancies” involving social, economical and political problems, and even the loss of “urbanity”. The focus should be shifted also on the reuse of existing buildings and “brownfields”: innovative uses and strategies should be defined in accordance with more complex situations including soil pollution, existing and underused architectures, lack of density and functions. Urban design should find new tools and

methodologies to deal with these trends in a different way: it is evident that urban renovation based on large and ambitious town plans (i.e. Milan “Bicocca” plan, by V. Gregotti) are no more effective and sustainable from many points of view.

Architecture, social challenges and the role of programs

Even if the effects of financial crisis are deeply affecting society, the causes that generated it still have to be solved (Rossi G., 2011).

Social needs are strongly and increasingly emerging - even if not like in the past - and they involve larger parts of the population.

Architecture and urban design are not autonomous: new or renewed social needs in the post crisis society concern housing (i.e. lack of or too expensive), but also working spaces, facilities, infrastructures, public spaces and all functions that affect urban quality and quality of life. Quality evaluations take over quantity ones: the failure of urban planning leaves the strong need for “urban” futures (Bertolino, 2013).

Architecture should also face the changing meaning of “community” (Moroni and Brunetta, 2011): different kind of “contractual communities” are possible (i.e. Usa, North Europe) and they reveal the potentialities of unexpressed needs in terms of shared spaces, activities, values. Which could be the effects of a larger diffusion of these kind of experiences on urban development?

The meaning of “housing” itself, between “private” and “non private” spaces (Riley, 1999), is rapidly changing accordingly to new life styles and to new enlarged concepts of “family”. The modernist approach to men’s needs and life organization is definitely over.

Architectural and urban design should actively act within this innovative framework, for example by dealing with flexible and multi functional layouts and realizing innovative social “programmes” (i.e. via Cenni Social Housing in Milan).

More flexible configurations can include also innovative and diversified housing, (i.e. temporary or co-housing) (Delsante, 2011), work spaces (i.e. coworking), creative , high-tech, or other forms of soft production spaces (i.e. start-ups, incubators, etc), and also other functions (Delsante, 2012). Functional mix and social diversity are some of the key words tracked in these experiences (Fernandez Per, Mozas and Arpa, 2011).

As a matter of fact, the architectural “program” (social, functional) becomes more and more important: a well defined program could better fit fast changing scenarios and social needs as well as the reuse of existing and underused buildings.

“What pressures - specific of the twentieth century -. does the combination of programs impose on architectural form?” (Holl, 2011); in other words, if post crisis architecture becomes “programmatic”, which are the effects on urban design and morphology?

Innovative tools and procedures to regenerate urban settlements

Many techniques and procedures could better meet the actual conditions of urban territories in the post crisis framework.

Updated or innovative public private partnerships (PPP) can better fit a more complex urban organization with multiple actors and wider needs. At district level, “private” driven requalification initiatives, even small scale (single or multi owner residential buildings), could become part of larger initiatives including public spaces and infrastructures (i.e. smart town projects).

Forms of “contractual communities” could also represent innovative ways to approach urban renovation: in some cases, groups of tenants organizing themselves to develop a refurbishment project of an existing building (i.e. Numerozero in Turin). Auto construction and participated

design processes represent the most meaningful examples of these experiences, whose effects should be deeply evaluated.

Other approaches support the “temporary” use or reuse of existing spaces and/or buildings (Bishop and Williams, 2012). Flexible, low-cost, light architectures and installations often reflect new forms of social organization (i.e. Temporiuso in Milan). These kind of transformations are usually connected with innovative “participation” processes, promoted by or agreed with public authorities. The results of these experiences are not only significant in terms of use of public spaces, and of transformation of unused spaces or land (i.e. taking care of “urban agriculture”), but also of reuse of underused or dismissed buildings with no chance to be transformed, as a consequence of the economic downturn and lack of private investors (i.e. Macao and the *Torre Galfa* in Milan).

All these different kinds of urban habits call for social sustainability and realization of innovative and flexible programs meeting the complexity of actual urban conditions. Which are the effects of complex, multiple and even temporary forms of renovation on urban design and morphology?

Needs are new and diversified, and the tools do not seem completely adequate: the “urban dilemma” is still not just economical, technical or even social but it is also a “*design*” issue.

Rubattino and Ortica districts in Milan

The districts of Rubattino and Ortica represent a meaningful case study to show the effect of post crisis design on urban morphology. They were originally constituted by two different historical settlements outside the “town” of Milan, along two important communication routes.

These historical centres are nowadays still recognizable but they were merged by urbanization process mainly after World War II. The history of both districts is strictly related to the industrialization process that started in the beginning of the XX century. Ortica area became a factory and railway neighbourhood with poor life conditions, that led to the development of social housing, whereas Rubattino was historically linked to big car factories such as Maserati and OM). Huge industrial yards are still visible on part of the original places, as a memory of that era.

The whole urban area of Rubattino and Ortica is historically (from the middle of XIX century) surrounded by infrastructures and strongly separated from the “planned” city (town plan by Beruto, 1884).

Figure 1. Aerial view of Ortica and Rubattino districts.

The west and south facing sides of the area are defined by the strong edge represented by the railway (the urban ring and the Milano-Venezia line), with high concrete walls showing strong differences in height: along the entire south and west perimeter just two small tunnels link the site to the town. Large inaccessible and unused spaces under the elevated highway (eastern ring

road) depict - as a matter of fact - the end of this urban district on the eastern side. Except for the huge industrial factories, large greenfields and agricultural areas are still present just outside this eastern edge: unfortunately, real estate development assisted by law procedures still continues to build new and meaningless “architectures” instead of recuperating the large amount of dismissed areas. This is a meaningful example of contradictory trends in contemporary urban settlements, between “endless” expansion and the complexity of reuse and reappropriation of urban vacancies.

Inside Rubattino and Ortica district different parts can be recognized, which are characterized by functional and morphological specific features: historical settlements with their monuments, social-housing blocks, big industrial sites, large old barracks, blocks of small factories, residential areas from post war expansion, recent and high density post industrial housing complexes recently recuperated for creative and cultural activities.

Figure 2. Urban fabrics with preservation and renewal areas.

Figure 3. “Transformation Areas” (in dark grey) according to the new PGT (Territorial Administration Plan).

The attempts to carry out an urban renewal in the middle of the ‘90s through large real estate plans suddenly stopped, and were partially unsuccessful, since some of the residential blocks

still need to be completed due to real estate crisis. Even if the reuse of outer dismissed industrial sites is still replaced by more convenient developments on close greenfields, some innovative and also temporary reuse of old manufacturing yards and buildings show a successful pathway to urban “regeneration”. Different buildings have been reused and rearranged for creative activities (i.e. fashion ateliers, designers’ studios, creative productions, etc): in addition to this, there is an extended use of underused or dismissed industrial sites during Milan Design Week (via Ventura district).

So, what to do with large underused areas and old barracks? Milan municipality recently approved a new Territorial Administration Plan (PGT, 2012) that supports new planning strategies, accordingly to a general vision of a “shrinking” town that is reducing its population. According to the new plan, within the above selected district we can distinguish two main “Transformation Areas”: the first deals with the site of the disused barracks of Rubattino, whereas the second one runs along some unused railway lines close to Lambrate station.

A truly “programmatic” architecture is needed to better meet the needs and the social transformation of the whole district: urban morphology should play an important role in defining strategies able to face the complexity and multiplicity of the urban structure. There are no actors (public or private) with the financial capacity of transforming the whole complex of dismissed sites, but there is the chance to transform them on the basis of a progressive, sprawled, multiple actor urban regeneration process.

Techniques for complementary urban analysis

Taking into consideration the complex urban framework and the lack of homogeneity in the urban fabrics, the aim of the research on Rubattino and Ortica districts is to deal with urban analysis in accordance with different approaches, showing their complementarities and effects on design strategies.

Post industrial towns are characterized by “differences” more than by homogeneity and the town is intended as a sprawled and open structure that cannot be reduced to a homogeneous system: “Appropriate techniques have to be found for identifying the character of these disparate places, defining it and developing its specific features, either by adding the missing functions or by perfecting the existing ones” (Ungers and Vieths, 1997).

There is still the chance to identify specific and recognizable features, also in a morphological sense, as already revealed by some urban studies years ago (Boeri, Lanzani and Marini, 1993).

Continuity and “separation” are two complementary issues of urban structure: they “are not the consequence of each other, but they are two simultaneous phenomena meant to reinforce each other” (Aureli, 2011).

The whole and its parts (Ungers and Vieths, 1997) should be recognized (i.e. “the town within the town”) and the post crisis urban territories identified as an “archipelago”: “the idea of separated parts links the possibility of an absolute architecture to the idea of the archipelago as a form for the city. The concept of the archipelago describes a condition where parts are separated yet united by the common ground of their juxtaposition” (Aureli, 2011).

Moreover, the superimposition of different urban elements (in time or in space) should also be read and interpreted (i.e. “the town as a combination of layers”). Differences and contradictions emerge and cannot be reduced.

Post crisis urban regeneration is characterized by morphological multiplicity and variety, with complementarities, differences, separation more than homogeneity and the uniformity of the “sea of urbanization”.

“Conflicts, fragments, unresolved contradictions and oppositions are, however, the original criteria of the “town as a combination of layers”. The various structures are superimposed, like the layers of a historical city [...] the variety of forms and spaces is intentional, the result of a clear and strictly defined process. This process takes into account the topographical and

historical factors, the techniques as well as the social requirements and formal concepts. Nothing is decided in advance, decisions are taken on a case by case basis” (Ungers and Vieths, 1997).

As a matter of fact, two approaches appear to be more appropriate to describe the features and morphology of Rubattino and Ortica districts: one is based on the idea of “archipelago” that describes the city as a unity of different and independent, though complementary, parts. It deals with typological and morphological features, more than with mere functional ones. The other one is based on the idea of the town as a “combination of layers”, showing the interference of different functions and “systems” (not just historically), and of contradictions and differences, also due to superimposition. The analysis of spaces through these different methodologies represents the chance for a comparative study.

The results of urban analysis, developed also within the course of Architectural Composition 3 held at the University of Pavia (Academic Year 2013-14 – by Ioanni Delsante; side professors: You Yinan and Nadia Bertolino) show the effectiveness of the selected methodologies.

Reading the city in layers led to a better understanding of the superimposition of historical developments, physical structures (i.e. rail systems), mix of functions and diversified spaces not just per dimension but also per role, use and quality.

Figure 4. Urban analysis by “layers”.

Reading the city in parts showed morphological “differences” together with functional and social “clustering” processes. “Continuity” and “separation” are two complementary faces also defined by the buildings themselves.

Figure 5. Urban analysis through “islands” and “archipelago”.

Urban analysis is the basis for the consecutive design activity: interpreting the urban complexity, also from a morphological point of view, can lead to define strategies that are more adaptable to fast changing scenarios.

Some design experimentation could better show the results of this process, but simply as an attempt and as a consequence of the interpretation of urban structure.

Some urban strategies clearly emerge and can be briefly described as follows:

- i) deal with the urban scale and dimension, and not with pre assigned perimeters or enclosed spaces. Relationships and enclosures are two complementary features, depending on specific site conditions. Urban morphology is one the key factors in defining the dimension and the “edges” of the project;
- ii) define a clear architectural “programme” with also different or progressive timing, including social, economical and functional goals;
- iii) take care of multiple actors or public /private initiative, with fragmented, complex or even enlarged perimeters in comparison with the fixed ones stated by planning regulations or “transformation areas”. Urban design supports flexible, progressive, inclusive strategies at urban level;
- iv) define a strategy in terms of preservation and transformation of existing buildings, with short and long term planning, also depending on economical conditions. Social needs have to be translated into a morphological strategy.

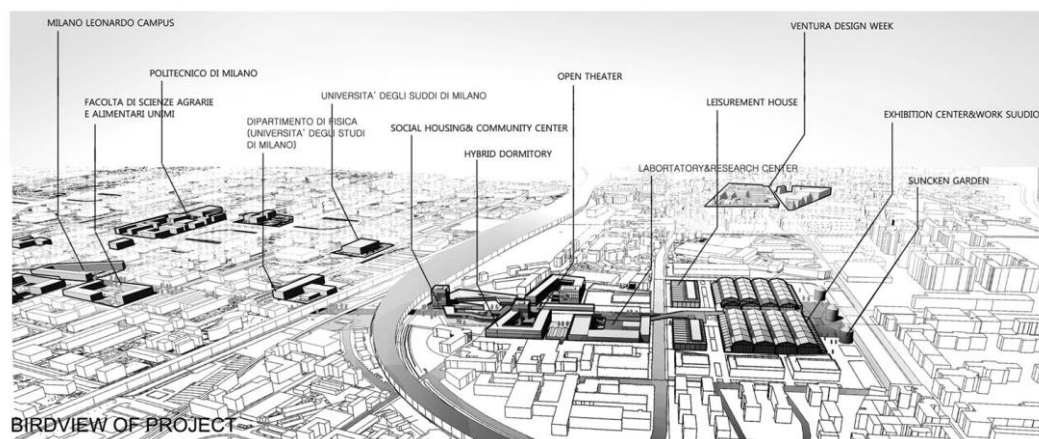

Figure 6. The project scale is urban, involving public and private actors in accordance with the specific program and goals.

Figure 7. Progressive design including existing buildings and public spaces.

Figure 8. View of one of the experimental projects: new urban shapes defined by reuse and addition of functions in existing urban fabrics.

Figure 9. The superimposition of morphological shapes on the existing framework.

Conclusion

Taking into consideration the post financial crisis framework and the conditions of urban settlements and architecture, urban analysis in Rubattino and Ortica areas should deal with selected methodologies to better meet and describe urban “complexity”.

Societal challenges and economical trends shift the focus of the project on the “program” that should be sustainable from many points of view, and not just technically.

Urban morphology plays an important role in identifying features, continuities and separations, also through differences and contradictions that fragmented or progressive programmes can realize in multiple steps and long term periods.

The results of the research developed on Rubattino and Ortica districts in Milan show the effectiveness and the complementarities of multiple urban analysis representing a meaningful case study in terms of coherence between morphological strategy and urban renewal techniques and tools.

Past and present: an architectural survey of Birni Lafia, a Dendi village

Jean-François Pinet

Faculty of Architecture La Cambre-Horta, Free University of Brussels (ULB), Place Flagey, 19 – 1050 Brussels. E-mail: jefpinet@gmail.com

Abstract. *How a city's architecture and urbanism, seen as particular manifestation of material culture, can reflect its identity? In collaboration with the multi-disciplinary project Crossroads of Empires, mostly composed of archaeologists and anthropologists, a group of architects conducted a study of contemporary villages of Dendi, a rural territory in north-Benin, bordering the River Niger. This architectural study was conducted in 2013 and 2014. The evolution of Dendi villages was only poorly documented since the first European explorations and the whole Crossroads of Empires project aims to emphasize the development of identity and material culture in northern Benin. A specific village, Birnin Lafia, was studied as a case study using a typo-morphological method of analysis combined with oral inquiries. This paper presents various aspects of the fieldwork.*

Key Words: North-Benin, field survey, urban morphology, rural area, anthropology of space

Introduction

Since two decades, the relationships between territories and identities are at the center of a debate that concerns social sciences in a methodological and epistemological point of view: in a globalized world, (Sassen 1991) do different territories prefigure specific cultural identities and reciprocally, do distinct identities involve specific territories? (De Biase, Rossi, 2006).

This link between territories and cultural identity is the core of the *Crossroads of Empires* multidisciplinary project, initiated in 2011 by Anne Haour, archaeologist and researcher at the University of East Anglia in Norwich, UK. The main goal of the project is to study to what extent medieval empires of the Sahel-Sudan (Cornevin, 1966) have influenced the political, economical and religious history of the regions surrounding the Niger River. In a more specific way, through a combination of archaeological diggings, compilation of oral traditions, comparative analysis of technologies and cultural studies, the project aim to understand how material culture was structured and dispersed between 1200 and 1850, at the start of European colonization. The period studied by the anthropological and architectural part of the project is more recent and starts around 1850 until the 2000s. Indeed, the majority of contemporary villages have emerged in the second half of the nineteenth century. The overall goal is to understand whether there are links between contemporary settlements and ruins discovered by archaeologists and to collect data on population dynamics through material culture and technical activities. In a region where the main historical sources available are relatively poor, the issue is also to establish if the results of the excavations are coherent with historical data from written documents and oral sources and to understand how the identity of this particular area developed over the centuries.

A rural territory in north Benin

Dendi is a key case study in many aspects. From a methodological point of view, Dendi is a narrow region (about 200 km long and 15 km wide), parallel to the axis of the Niger river, which may be covered systematically. This territory, almost virgin of any scientific research, is

at the edge of two of the largest well-known historic areas of west Africa (Kanem and Bornu empires to the west and the succession of empires of Ghana, Melli and Songhai to the east) and a myriad of kingdoms (Hausa city-states, Sokoto caliphate, Gulmantchéba kingdoms). These empires and kingdoms were subject to different studies, allowing a comparative approach. Because of its location, the Dendi was the theater of major population movements and has long been a crossroad of ancient trade routes linking the Hausa cities to forested areas currently known as Ghana. 'Marginal territory', 'crossroad', 'refuge area' : the commercial, military, demographic history of Dendi explain how this territory can be so heterogeneous in both linguistic, ethnic and technical level.

Figure 1. Map of main medieval West African empires.

These population dynamics, particularly complex, result in considerable ethnic diversity in the region and the creation of one own cultural identity, but also by the formation of a two-headed political power where the leadership of the land belongs to groups of farmers identified as indigenous or natives while the leadership of the villages and people is in the possession of non-native groups of warriors designated as newcomers or non-native and usually coming because of the fall of the Songhai empire (Haour, 2013).

It is important to stress the difference between Dendi as a territory, dendi as a language, the dendi cultural area (that far exceeds the boundaries of the region) and the dendi identity. The same term is used to designate the language, territory and the people who live there, even if they are very heterogeneous. The literal translation of dendi is 'go downstream' or 'down the river' (Bako Arifari, 1998). The term does not refer to an ethnical connotation but geographical, the river in question is the Niger river.

The dendi 'culture' or 'identity' is an inclusive culture that tends to assimilate elements which are originally foreign. The Dendi language or *dendi cine* is a vehicular language and therefore shared by different ethnic groups. The notion of a 'dendi ethnicity' seems quite questionable and seems to rather be a result of the construction of a shared identity by inhabitants, in order to make bounds between different ethnical groups. This structure was reinforced by the impact of colonizers who had a tendency to regroup people of this territory under the same name (Bako Arifari, 1998).

Available historical records regarding Dendi are relatively rare. Except for some sketchy references present in the Tarikhs (Houdas, Delafosse, 1913) and memories of european explorers and military (Barth, 1959; Toutée 1897; Drot, 1904) the main information about this area during the last centuries came from colonial administrators (Larose, Perron, 1924 Ardant du Picq, 1933 Sere River, 1965) and studies from the late 1980s (Bio Bigou 1987; Bako Arifari

1989; Baka, 1992; Dembou, 1992; Whalter, 2006). Most of these studies are master thesis of history or PhD theses which investigate the political upheavals in depth but discuss little the daily lives of people and rarely describe architecture and environment.

During the French colonization, the Dendi territory was largely marginalized in the reports because it was too remote and lacked natural resources. The increase of forced labor between 1920s to 1930s seemingly also had a strong impact on the area, not concerning migration, but also construction techniques and to a certain extent, material culture. For example, some people left to border regions or to cities in order to escape the forced labor and upon their return, they brought with them habits, techniques and customs foreign to the dendi (Vennetier, 1976). After the independence of Benin in 1960 and two revolutions in 1963 and 1972, a new political way of functioning in the village chiefdoms was introduced.

Transmission of the function of village chief, previously hereditary became subject to an election. Therefore, the ruling dynasties in the Dendi were on a large scale overthrown for a time. However, this change in the system appears to have concluded into some form of compromise since the 1970s: it is often the 'legitimate' heirs who presents themselves to the electoral vote.

The place of architects in a multidisciplinary study project

The integration of architects in the project team provides new skills and a reflective analysis based on an architectural survey of built forms and existing habitats, a quality relatively unique in this type of archaeological study. Alongside the archaeological excavations, we had to develop a method of analysis suitable to the field, complemented by interviews with inhabitants.

Although the typo-morphological method of analysis was born in Europe in the 60s, in the context of 'sedimented' cities with relatively 'steady' models (Muratori, 1960), we believe that this method, by its phenomenological and essentially descriptive nature, is adaptable to African territories that are, urban or rural. Analysis of African cities using the tools of typo-morphological method of analysis without necessarily declaring itself as such already exists (Maas, Mommersteeg 1992; Bourdier, Minh-ha 2005). The analysis of rural dwellings, which dates back to early eighteenth century (De Foville, 1894 Brunhes, 1920) has quickly emerged as a hub of questions about society and the theories that were elaborated on it. Rural areas, villages and houses, but also the old neighborhoods of our cities have become a pertinent laboratory. (Rivière 1941, Lévi-Strauss, 1958 Chombart Lauwe, 1959, Bourdieu 1969).

If cities have the ability to integrate into their framework social and urban mutations while keeping traces of their past development states, rural villages, mostly composed of concessions made of mud and lasting rarely more than a generation, seemed to be *a priori* much more sensitive to any urban upheaval and therefore much more difficult to analyze. Our assumption, which was verified during the field survey, was based on the hypothesis that urban structure (roads, parcels and to some extent the implementation of buildings on the plot) persisted over time, although the buildings themselves were renewed regularly. In that way, the study of the contemporary state of Birni Lafia can provide actionable insights on its previous states on the urban scale but also on the typological scale by studying the evolution of construction techniques and building types (Garmy 2012).

By questioning spatial arrangements, urban structure and space appropriation, it is possible to address issues studied by the entire project team. By understanding the architecture and urbanism as the expression of a specific material culture or 'identity' and trying to understand how people live, the village's history and its development based on personal and families stories, we were able to open some 'doors' on other specific knowledge.

It was thus to understand whether there were recurring structures passed on over generations, observable on both an urban and architectural scale. These specific elements of material culture of the studied city should be not necessarily unchanged over time but consist in what Ryckmans identifies as a permanency. *'Permanency is not what denies transformation, but what informs it'*.

(Ryckmans 1991). The identification of these elements and their description should provide the basis for a typological classification.

Figure 2. Relationship between Birni Lafia and other cities.

Site

In 2013, we chose to work on Birni Lafia, a village whose name comes from the hausa words *birni* (enclosure, wall) and *lafia* (health). This choice was made initially for very practical reasons : Birni Lafia was the location of the base camp of archaeologists. Without cars at our disposal, it greatly simplified our logistics. In more methodological terms, the size of the village allowed us to do a detailed and fairly representative field survey, and which could lead to an understanding of the 'whole picture'. Finally, because the idea was to understand links between the existing villages in the region and ruins discovered during archaeological campaigns, Birni Lafia turned out to be an interesting site by its proximity to one of the major archaeological excavation sites in the region.

Birni Lafia is located in the north of Benin, on the right bank of the Niger river. Major cities around Birni Lafia are Karimama and Kompa in the north, Tenda and Gaya in the east, on the left bank of the Niger river and Malanville and Guene in the south on the Benin side. If the city is located 4 km far from the river, its adjacent to the river basin which is around 7 km wide close to Birni Lafia. These lands, cultivated by the inhabitants mainly to grow rice, tomatoes, peppers and onions, are water covered during the annual floods which regularly flood new areas in the north of the village.

Before the field survey, we created a map of Birni Lafia based on satellite pictures of the village. From a methodological point of view, this process may seem somewhat risky because of the many uncertainties that include: poor definition of the pictures can lead to confusion in the interpretation of the elements, the scale can be subject of a margin of error, foliage can hide certain elements... In fact, this work was relatively accurate as we have seen during the subsequent field campaign. This process has allowed us to quickly produce a map highlighting the existence of circular and rectangular buildings, the presence of voids within the framework, some roads and on the whole, the overall shape of the city. During this fieldwork, mapping fences and walls that were mostly missing in the first map allowed us to understand the geometry of concessions and establish an preliminary land registry.

During the campaign conducted between January and February 2013, we interviewed 114 people in Birni Lafia using a survey form asking the identity of the inhabitant (name, age,

ethnicity, activity), their level of wealth (oxen or cow number), some genealogical information and family history or village history in general and, finally, architectural information (floor plans to fill in, technical or specific information). We compared this research material with archaeological data and information based on a cartographic analysis mostly conducted on the network of roads and land plots in the city. Family trees that we could reconstruct from interviews with inhabitants indicate that the village has existed for five or six generations on average. Assuming that the average length of a generation is 25 years, it can be estimated that the village exist since 125 to 150 years, which actually place his creation before 1900, during the second half of the nineteenth century.

Urban form

Globally, the shape of Birni Lafia corresponds to that of an almond which the more slender side would be headed north. The village has a more densely built area which we will call 'center' and a less dense area that can be described as 'peripheral area'. The boundary between the two is quite porous, fuzzy. The town is bisected by a highway that follows a north-south axis. Eastern part of the village is more important than the western part. Dimensions of buildings are repetitive and regular. At first glance, their disposal seems random. However, taking into account the fences and walls, we can discern houses that form coherent sets.

The identification of the locations of political, economic and religious powers places, based on the descriptions given by the village inhabitants, suggests that the village that once functioned on a radio-concentric pattern around the village chief and land owner houses, changed to a linear model. The market, the administration, the school, the main mosque of the village are located around the road, as a kind of 'strip' (Venturi, Scott Brown, Izenour, 1972).

The transition from one model to another appears to be related to political and historical circumstances: the states of war promote compact forms, easily defensible. Since the French colonization and the appeasement of tensions between villages, the village could take another shape, more suited to its economic development, polarized by the highway. This evolution of a radio-concentric shape to a linear shape seems to be common across the Dendi and has been observed in various other villages in 2014.

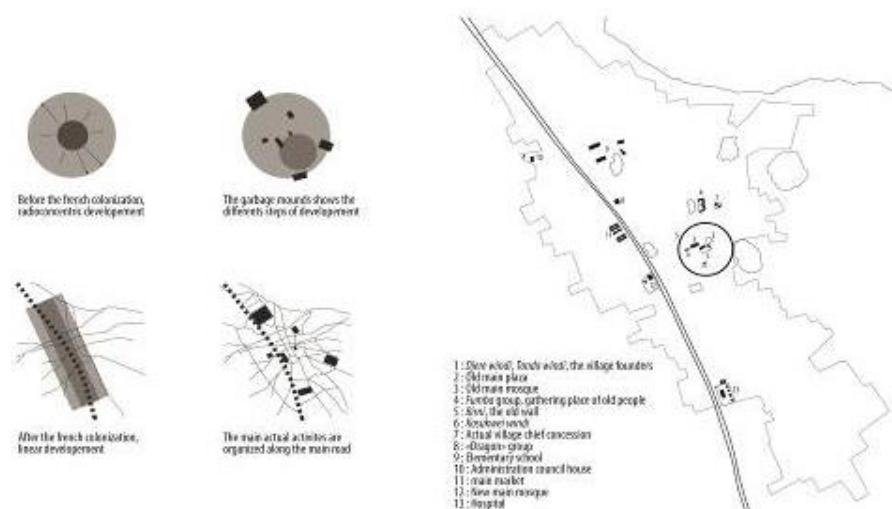

Figure 3 and 4. Hypothesis of development: the influence of french colonization & Old and current main places of power.

Borders

The territory around Birni Lafia is relatively empty, dotted with isolated villages. It is not a context of dispersed housing. It is therefore quite easy at first to draw the outline of a city.

According to the interlocutors the various entities that compose the city vary in number. The designations used also change. Based on their interviews, Birni Lafia seems to be composed of two large areas.

The first one is the 'old town' or *kwara zema*, which includes the oldest parts of the village, whose boundaries correspond to the former surrounding wall (the *birni*) and which corresponds to a dense 'core' containing no fields. It is also the part of the city where the vast majority of the holders of traditional power still live today.

The second one is the 'new town' or *kwara tegui*, which surrounds the old city and which boundaries are less defined. From the study of building density, we have chosen to divide it into two subgroups: a first periphery moderately built, interspersed with large open spaces where we can see some fields and a second periphery, less built and much more recent, comprising mainly fields and a few isolated houses. This third entity acts as transition between the first two and the bush.

The boundaries between these three entities are sometimes materialized by a street, a row of trees, granaries or may be intangible, symbolic.

To this relatively common to all respondents division is superimposed over a second division in quarters which corresponds more to ethnic or family groups and, in this case, vary to a large extent from an interlocutor to another. The 'confusion' in the designation of quarters probably reflects power struggles (Rozenholc, 2004)

The *basfonds*, or clay extraction areas, that have been flooded later for some and became small artificial ponds where fish farming is practiced, were clearly identified by locals as markers of extension of the city. According to the myths of creation of Birni Lafia, the first settlement was surrounded by piles of garbage. When the village expanded, new piles were made at its limits and residents dug new clay extraction areas, marking steps in its evolution.

Roads layout

Two structures appear when studying roads of Birni Lafia: in the most central part of the village buildings are aligned along orthogonal roads, very regular in contrast to the tortuous paths which are distinguished elsewhere.

During the field survey, we understood that this transition from an organic road framework to orthogonal roads is a legacy of colonization. Indeed, after colonizing Benin, the French did not only built the highway that cuts the village in two but also ordered to inhabitants of different villages, including Birni Lafia, to create roads, that people call *vons*, following a orthogonal layout.

This work, which respond to a hygienist, military logic and should serve as firewalls, are not unlike, on a smaller scale, the boulevards Haussmann carved in central Paris, relatively speaking. They created a major trauma in the collective consciousness. During the interviews, inhabitants explained that the French have 'broken the village' when they forced people to destroy some houses to trace the *vons*. The French also tried to force people to align their homes on *vons* but it was not very effective.

Due to their irregular pattern and reduced size, the *fondos*, which can be translated in English by 'path' or 'trail', appear older than the *vons*. Some *fondos* are referred to as *fondos ndangaize* or 'where only one foot passes' and correspond to very narrow alleys. Besides this, the status of *vons* and the *fondos* differs : while *vons* are a public shared space without owner, *fondos* are a private, shared space. Among the *fondos*, we can distinguish paths that connect two open housing groups mostly used by the residents and paths between different housing groups, bordered by mud walls or straw fences. Even if they are originally a private shared space,

temporary they receive the status of public space or path and are used in some cases as an right of way, a more or less forced servitude

In Birni Lafia, we can perceive three logics in the pattern of roads. First, the colonial logic that led to the development of the orthogonal layout of *vons*. The second logic relates to the site, the topographic morphology of Birni Lafia and the third logic is the expression of the social relationships between the inhabitants (White-Pamard Quinty and Bourgeois, 1999). Both the second and third logic are used in the organization of *fondos* (White-Pamard Quinty and Bourgeois, 1999). The hierarchy of the social structure in Birnin Lafia seems to have been highly hierarchical, based on a caste system (e.g. oldcomers, newcomers and slaves). Therefore, it is possible that the obligations or prohibitions that bind clans, families and everyday relationships (e.g. ceremonial greetings, necessity) have determined the location of concessions (which must be allowed by the dual power of land chiefs and village chief) and pathways between concessions. Pathways and in particular some *fondos* have specific purposes determined by daily activities. For example, people greet each morning the old 'aunt' or 'uncle' of an affiliated family to inquire about his health or women ask for condiments to allies rather than feuding families that could poisoning it. One will thus avoid some concessions. Similarly, one will not enter impunity in the housing group of a sorcerer or a leader.

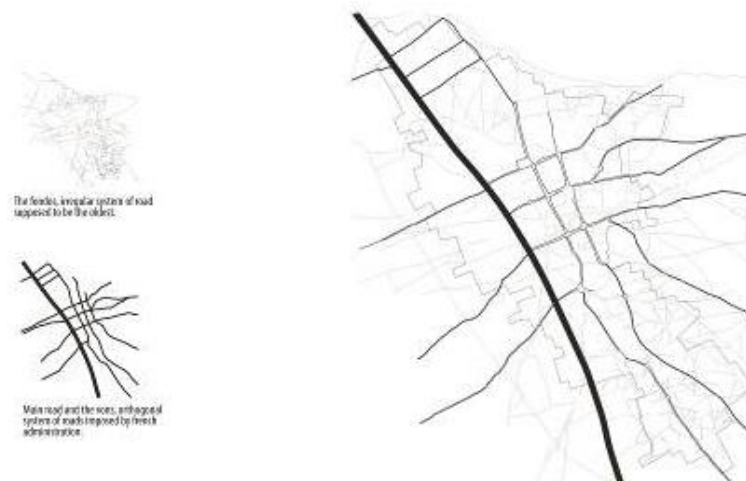

Figure 5. Two roads structures.

Plots layout

Before the survey, due to the lack of any land registry, we did not have prior information about plots. The limits defined by the people during the field survey helped us to develop an approximate plot map. This map, open to changes, provides information related to the size and geometry of the plots.

By analyzing plot sizes, it is important to quantify the order of magnitude of variations between large and small plots. If the difference in size between the families of plots is small (e.g. one or two), the study of dimensions is not necessarily very significant. However, if the difference is higher (e.g. one to five, one to ten or more), it can be used as a tool for defining the types of plots (Panerai, Depaule, Demorgon, Veyrenche, 1980). In our field survey, we mapped a difference between plot sizes in medium of one to five.

We defined two groups of plots: a group of small irregular plots in the center of Birni Lafia and a group of large orthogonal plots located in the outskirts of the village. The orthogonal plots seems linked to the *vons*, a road pattern itself orthogonal, while the irregular plots seems more linked to the *fondos*. However, this rule is not absolute. As the *vons* have superimposed the layout of the oldest roads, some irregular plots were served or cut by the *vons*.

Considering the hypothesis that due to the inheritance process from generation to generation, the plots, handed down from generation to generation, are successively subdivided, then the size of the plots could be interpreted as a marker of anteriority. Although this hypothesis is validated by the testimony of the inhabitants, we must nevertheless moderate it. For example the smaller parcels are not necessarily the oldest. It would be useful in this regard to report swarming issues or on the contrary dividing plots issues. The field survey showed that the majority of smaller parcels are occupied by the descendants of slave families. In addition, some plots do not appear to have varied in their dimensions over time, or just a few. Then, can we consider that there are optimum dimensions for the plot? Is there a density of building or a configuration from which the heirs choose not to share their land but to create new ones ?

Transmission of plots is still complex to understand. It is difficult to find a recurrence in inheritance. It is not always the eldest son who inherits the plot. In some cases, because the eldest son got married and was too old to stay with his parents, he leaved the housing group and created a new plot. In this situation, the youngest son remained until the death of his parents and inherited the whole plot. How inheritance is distributed in the case of a larger family? Within the limits of our study, we have not been able to answer these questions precisely.

Are there different modes to occupy a plot depending if the owner is part of one or the other groups mentioned above? Some plots are constructed on the entire surface while others are built on only a part of their surface, the other being left empty.

The buildings in general are organized around a courtyard called *windi guende*, where one or two trees are planted. This courtyard is the centre of the housing group and a shared living space. In addition to this, the position of the buildings on the plot obeys in one hand to the geometry of the plot, and on the other hand to the location of the plot in the village. For example, the organization of an isolated plot is not the same as that of a plot located in the village centre or along the highway. All the buildings follow the non-adjointing rule imposed by the French military as a protection against fire.

Building types

Buildings or *fou* of all the concessions that we could visit in Birni Lafia are very repetitive and can be classified into six types. The first one which seems to be oldest type, is a circular building in mud bricks called *kouroukoutou*. The other five types are orthogonal buildings called *kata*, *werenda*, *cheroga*, *kabanda* and *salon*. Apart the obvious anteriority of the *fou kouroukoutou*, we are currently unable to determine whether one of the five type is older than another. It is highly likely that the five orthogonal types have been introduced in the Dendi in the same period and that the choice to build any specific type is due to the owner's personal preferences or his means and eventually the geometry of the plot.

By analysing the changes in building typology depending on the ethnicity or main activity of the occupants, we noticed that some professions mark the appartenance to an ethnic group or a caste, even nowadays. In Dendi, in a certain time in history, potters and dyers were slaves. Nothing can distinguish the homes of their descendants in typological terms from those of others. During interviews, some people had explained that the buildings were all the same, regardless of ethnicity but '*fetishes changed*'. Then, how can we perceive the invisible? We observed that some families brought more attention to cleaning their courtyard than others, but this does not seem really significant and it is more related to each family customs. It is possible to find smoking rooms and nets in the fishermen houses while in a home of blacksmiths or potters we could find other very specific tools. That is the only difference we observed besides the difference in size of the plots.

We elaborated two hypotheses about the changing of building typology from circular *fou kouroukoutou* to orthogonal types. According to our first hypothesis, the most evident, this transformation is related to the influence of colonization and is a side effect of forced labour. The villagers have reproduced the internal organization of buildings constructed for the settlers

and have replaced the traditional clods of clay, straw roofs and techniques plastering by adobe bricks, concrete and tin roofs.

However, a second hypothesis arises due to the fact that European explorers described starting from the eighteenth century orthogonal constructions with flat roof in Tombouctou, Djenne and in other major cities of the region. The medieval empires and kingdoms of the Sahel-Sudan have long before developed a building typology of their own, in constant dialogue with the Arab-Berber architecture and material culture conveyed through caravan trade (Cissoko, 1996). It is possible that this Arab-Berber architecture was disseminated in all territories controlled by the medieval West African empires and may have influenced the Dendi architecture.

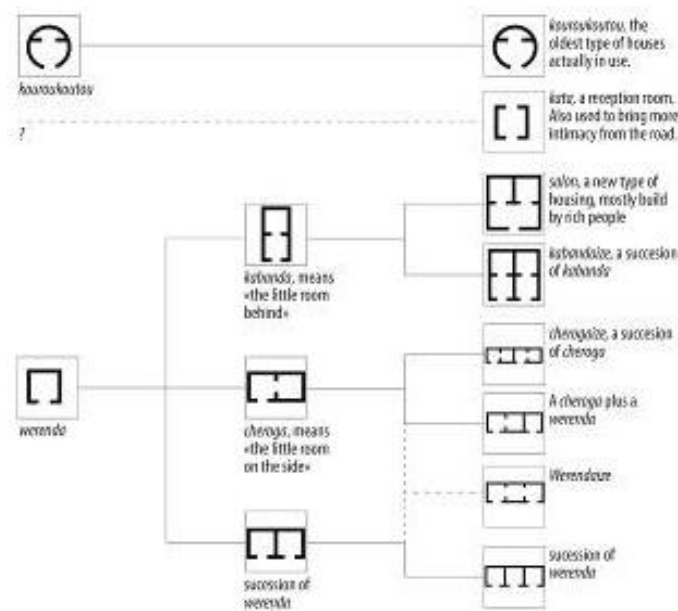

Figure 6. Building types 'genealogy'.

Conclusion

The work during the field survey was challenging and enriching because it implied the need to adapt a methodology and a language usually used for architectural and urban research in a multidisciplinary team composed mostly of archaeologists. The typo-morphological method of analysis proved to be very effective in the fieldwork, especially when it was coupled with interviewing inhabitants. By articulating social analysis and spatial descriptions, we wish to develop a fundamental research on the anthropology of space. (Twitchell Hall, 1971 Van Eyck, 1972 Paul Levy and Segaud, 1983; Depaule, 1994; Choay, 2006; Segaud, 2007).

The anthropology of space is not yet a well defined discipline, but is more a common thought, a common attention given by researchers and authors from different disciplines usually dealt with separately. The method used by anthropologists for developing knowledge has long been the one, 'malinowskian', of the 'detailed study of a defined area' (Stocking Jr. 2003) and in this context, the correspondence between identity and territory was proved particularly interesting with regard to the Dendi.

Figure 7. Axonometrical view of the east part of Birni Lafia.

Dendi villages that we visited are currently in a process of transformation. Far from being influenced by the globalized trends while remaining in a form of marginality, they suffer radical changes, visible from one year to another. We observed transition of some architectural and urban forms as well as of some construction techniques to other forms and techniques. The passage of the circular types of buildings to rectangular buildings is also observed in the nearby regions (Augustin 1994).

Among the various results collected, the study highlighted the impact of French colonization in the structure of villages and architectural techniques. Transformations of the urban form and of architecture stand as evidence for the political and social changes in the region and are observed also in other Dendi villages. There are not many architectural characteristics from one village to another or from one ethnic group to another. The people have clearly explained that *'they built the same as other people where they live.'* Thus, despite a very heterogeneous population, due to the long history of evolution and the influences from the West African medieval empire, the Dendi identity in general terms remains homogenous.

Urban form and its implication for the use of urban spaces

Antonio Tarcísio Reis

Faculty of Architecture/PROPUR, Federal University of Rio Grande do Sul.

E-mail: tarcisio@orion.ufrgs.br

Abstract. *The objective of this paper is to discuss urban form and some of its implication for the use of urban spaces. The relationship between urban form characteristics, such as those related to type of building use and amount of visual and functional connections with the public open spaces, and presence of people are considered. A comparison is made between 'traditional' urban form and 'modernist' urban form. In a 'traditional' urban form buildings have front doors and windows facing the public streets, whereas in a 'modernist' urban form buildings tend have doors and windows far away from the public streets and/or facing inward open spaces with no distinction between front and back windows and doors. Therefore, examples from cities in different countries are used for the comparisons and reflections involving these issues. The main outcomes from these discussions emphasize the need for a better understanding regarding the implications of urban form for the use of urban spaces. Additionally, type of building use and amount of visual and functional connections with the public open spaces tend to have significant consequences for the vitality of urban space.*

Key Words: *urban form, use of urban spaces, traditional urban form, modernist urban form.*

Introduction

Mainly after the Second World-War the urban form has been shifted from its 'traditional' characteristics to a 'modern' approach. Whereas the first is characterized by a direct relationship between buildings and public open spaces, the second is characterized by a loose relationship, with public open spaces merely resulting from the layout of blocks of flats.

Figure 1. Ouro Preto-Brasil.

Figure 2. Diamantina-Brasil.

Figure 3. Prague-Czech Republic.

Figure 4. Porto-Portugal

In a 'traditional' urban form, as in Ouro Preto (Brazil) or in the historic areas of Prague (Czech Republic) and Porto (Portugal), buildings have front doors and windows facing the public streets, whereas in a 'modernist' urban form, as in the residential superblocs in Brasília (Brazil), buildings tend have doors and windows far away from the public streets and/or facing inward open spaces with no distinction between front and back windows and doors.

Although, some authors (i.e., Gehl, 2010, 2011; Jacobs, 1984) have highlighted the importance of the relationship between buildings and open spaces, as has been the case in the 'traditional' urban form, the 'modernist' urban form, the 'modernist' urban form appear to be the model for most of the contemporary planning including university campuses and residential areas of Olympic Parks or equivalents such as the Residential Vila of the Pan-American Games in Rio. Therefore, there is a need to further discuss the implications of the 'modernist' urban form in comparison to the 'traditional' urban form.

Hence, the objective of this paper is to discuss the urban form and some of its implication for the use of urban spaces. The relationship between urban form characteristics, such as those related to type of building use and amount of visual and functional connections with the public open spaces, and presence of people are considered. A comparison is made between 'traditional' urban form and 'modernist' urban form. Therefore, examples from cities in different countries are used for the comparisons and reflections involving these issues.

Relationship between buildings geometry and street alignment

In the 'traditional' urban form, for example, in the historic areas of cities such as Ouro Preto or Diamantina, Prague, and Porto, buildings geometry have a direct relationship with street

alignment, its main façade plane being parallel to the street alignment. This allows for these buildings facades being part of a person's visual field while walking, enriching the aesthetic experience and making easier the connection between people and the buildings. Nonetheless, in the 'modernist urban form' this relationship tend to be broken, mainly after the Second World War, when the 'Unité d'Habitation' designed by Le Corbusier, was built in Marseilles between 1947 e 1952, following the modernist ideas such as the inclusion in a single large scale block (140 meters long, 24 meters wide, 56 meters tall and 19 floors, including the ground floor on stilts and the rooftop terrace) not only residential units (337 flats) but also service, commercial and leisure activities such as post office, laundry, general and food stores, restaurant, hotel, gymnasium, kindergarten, a 300 meters jogging track (Curtis, 1996; French, 2009). The layout of the 'Unité d' Habitation' follows the east-west orientation of its longer facades, provoking a misalignment of the block to the adjacent street, and a lack of a direct relationship with the public open space. This lack of relationship or geometrical coherence tends to make the visual perception and so the aesthetic experience poorer, what also tend to negatively affect the use of urban spaces. Sítte (1992) have criticized the irregularity of the streets limits caused by the recede and advance of building facades, affecting the perception of continuity of the built perimeter in the interface with the street space.

Visual and functional connections between the buildings and the open spaces

The visual and functional between the buildings and opens spaces tend to have an effect on security and vitality of open spaces (Gehl, 2010; Jacobs, 1984). These connections allow the visual supervision of open spaces by those inside the buildings and the requests for help as well as the demand for refuge by those in the open spaces. In the 'traditional urban form' such visual and functional between the buildings and opens spaces tend to be present while the opposite frequently happens in the 'modernist urban form' . Moreover, while the visualization of openings in the buildings generate visual stimulus creating a more satisfactory aesthetic experience, the lack of visual stimulus provoked by the blind walls generate a poor aesthetic experience for those using the public streets.

Figure 5. Terraced houses in Porto Alegre, RS, Brasil.

Figure 6. Sapucaia Estate, Sapucaia, RS, Brasil.

This interface or edge between the buildings and public opens spaces constitutes the facades that are closely experienced, is part of the places where we walk in the city, is where we come in and out of buildings, where the inner and outer urban life can interact; this interface, particularly, at ground floor level has a decisive influence on urban space vitality and must have a certain degree of transparency or visual permeability (Gehl, 2010). The existence of narrow units and many doors, complemented by a wide variation in functions provide many points of exchange between inside and outside and many experiences (Bentley et al, 2013; Gehl, 2010). Therefore, while ‘soft edge’, such as a shopping street with its windows, attracts and retains the pedestrian, a ‘hard edge’, such as blind walls at ground floor, does not attracts the pedestrian since there is nothing to see, not even the frame of a window (Gehl, 2010). In Miami, the urban planning legislation was recently revised establishing new rules that propose to integrate individual ownership with the public sphere, leading to ground floors with adequate activities and levels of visual and functional permeability (Miami 21, 2010).

The existence and type of use in the ground floor and the public open space

Together with other factors (i.e. visual and functional connections) ground floor use is an important issue to be considered in the relationship between buildings and public open spaces, since the existence of adequate type of use can contribute to the urban dynamics, making the urban experience safer and more aesthetically pleasing, this being the usual characteristic of the ‘traditional’ urban form (Gehl, 2010, 2011). On the other hand, ground floor inadequate use such as parking, lack of eventual use or permanent use as provoked by stilts , does not have the potential to contribute to urban dynamics. Access to garages or parking areas can fragment the edge between buildings and public open spaces and weaken or compromise the idea of continuity (Gehl , 2010). In Brasilia, the modernist principle of stilts is normally present in the residential buildings, preventing the building from having a direct connection with the public open spaces (Holston, 1993).

The distance between the buildings and the street

In the 'traditional' urban form buildings usually are closely connected to the streets, on the perimeter of the block, while in the 'modernist' urban form, mainly after the Second World War, buildings tend to be disconnected from the streets, being located inside a block, defining a layout characterized by isolated buildings interspersed with empty spaces, as in the residential superblocks in Brasília, and in many university campuses and in residential areas of Olympic or Pan-American Games. Therefore, while in the first situation the city user is invited to look at or/and to go inside a building, in the second case the user is kept away from the building and so from its direct visual and functional impact; in this case, what is first perceived is the void or the open space in front of the building and not the building itself. The cohesion or contiguity of buildings defines a permeable wall for urban open spaces and is responsible for the harmonious effect of the whole due to the continuous enclosure of space by buildings (Sitte, 1992). The cohesion reflects the potential for visual appeal far higher than an isolated building or buildings containing voids between them (Cullen, 1971). Hence, the urban experience tends to be poorer in the 'modernist' than in the 'traditional' urban form.

Definition of open spaces by buildings and user control

In the 'traditional urban form' open spaces are generally defined by the buildings creating an interaction between the open spaces and the buildings with positive results for the use of open spaces (in many cases, such use is an extension of the use inside the building), potentially improving security and the aesthetic experience of urban spaces. These open urban spaces tend to have a clear hierarchy (i.e. regarding what is a public and what is a private space), definition and control.

Figure 10. Istanbul, Turkey.

Figure 11. Porto, Portugal.

Figure 12. Vienna, Austria.

On the other hand, in the 'modernist urban form' open spaces tend to be left over spaces, with no clear definition and control and with no clear connections with the buildings, and so, without clear purpose of use. Therefore, the consequences generally are a poor visual experience due to the lack of nearby building facades generating visual stimulus and a lack of use or the existence of inadequate use. This can be exemplified by the illegal occupation of communal open spaces for private uses (i.e. building of garages and barbecue area) in many housing estates in Brazil characterized by the 'modernist urban form', with negative consequences, for example, concerning aesthetics, the use and security in the open spaces (Reis and Lay, 2012).

Additionally, in the 'traditional' urban form buildings tend to have a front and back regarding its relationship to public urban space. The front facades themselves define the sidewalks or have some retreat giving room to a private front yard, whereas the backyard has a greater degree of visual and aural privacy in relation to the space of the public street. On the other hand, the 'modernist' urban form has eliminated the front and back of buildings, and so, the different levels of privacy, either in the open spaces as well as inside the buildings, promoted by these differences.

The 'conceptual' or the 'identity' open space, and social interaction

An open space that can be perceived as having an identity, a character, due to its definition by the formal attributes (i.e. height and fenestration) of buildings and their relationships to the open spaces, tend to be present in the 'traditional urban form' and lost in the 'modernist' urban form. The 'conceptual' (Prak, 1985) or 'identity' space appears to be perceived not only as an aesthetic qualified space but also as an inviting space for people to stay and carried out some social activity. Analyzes carried out by Holston (1993) in Brasilia showed that residents of

superblocks rejected the street characterized by an absence of connection with the buildings, since it does not stimulate social interaction.

Figure 13. Pan-American Games Residential Vila – Rio de Janeiro, Brasil.

The absence of a continuous sidewalk bordered by the facades of buildings made the street to lose its characteristic of attracting people to go for a stroll, and so, reduced pedestrian movement on the streets (Holston, 1993).

Repetition of identical large scale horizontal or vertical blocks in a vast open space

The repetition of identical large scale horizontal or vertical blocks in a vast open space has been a common layout adopted in the 'modernist' urban form, as shown in the designs by Le Corbusier such as 'La Ville Contemporain', the 'Plan Voisin', and the 'Ville Radieuse' (1930).

Moreover, the internationalization of this urban form has reached Brazil, as in the case of the design in 1942 by the architect and urban planner Atílio Correa Lima and his team of the Várzea do Carmo Housing Estate in São Paulo (Bonduki, 2004), and Brasilia. Residents of standardized superblocks in Brasilia, criticized the lack of differentiation of buildings and its consequently monotony and impersonality, with no visible personalization by residents, due to their difficulty in doing so (Holston, 1993). Two housing estates are emblematic of the problems caused by the intense repetition of identical large scale horizontal or vertical blocks in a vast open space, namely, Pruitt-Igoe

, in St. Louis, Missouri, U.S.A., and the Killingworth Housing Estate in Killingworth, north east England (Greger and Steinberg, 1988; Kellet, 1987; Reis and Lay, 2012), giving support to the following: "The uniformity and rigidity of 'modern' housing estates all over the world has lead to drastic problems of negligence, lack of maintenance and even vandalism – as a form of helpless counter-reaction of its inhabitants." (Greger and Steinberg, 1988, p.23). The Pruitt-Igoe housing project was partly demolished 20 years after its completion and occupation in the mid 1950s, been planned to house about 15,000 people in a group of 33 widely spaced, 11-storey, high-rise buildings. Although some point to social and economic problems as the main reasons for its demolition (i.e., Montgomery, 1977), others emphasize that the modernist design of Pruitt-Igoe was a strong determinant of its failure to satisfy the residents, like Peter Blake (1977), in his book 'Form Follows Fiasco - Why Modern Architecture Hasn't Worked'.

The Killingworth Housing Estate, an award-winning project, with high quality of construction and detailing, was demolished in 1987, only 15 years after its completion. Containing 740 housing units in 27 multi-storey towers of 6 and 10 storeys, it was designed to accommodate 3,292 inhabitants. Although social, economic and political factors can be associated with the its demolition, and even poor management as pointed out by the architect who designed the Killingworth Towers as the main cause of problems, design problems were evident. Even though the majority appeared to be satisfied with their new homes, with generous

internal spaces, central heating and bathrooms at a high standard compared to the old housing, 'people in a position to choose preferred traditional low-rise houses with gardens, to multi-storey accommodation' (Kellet, 1987, p.5). Moreover, the fact that residents did not like the overall layout of the estate can be illustrated by the fact that the bleak, monotonous, large-scale and above all unattractive appearance of the estate may have influenced people to leave (Kellet, 1987), and by the following declaration that show that although the dwellings themselves were well liked by the residents, the problems with the housing estate design were clearly expressed:

They [dwellings] were nice inside when you shut your door. Beautiful, we had them lovely (and) couldn't have asked for anything else. We all said that we would have liked to have taken our houses (out of the Towers) and put them on the ground somewhere (in Kellet, 1987, p.7).

Additionally, results from research about urban aesthetics (i.e., Reis *et al.*, 2011), give support for the fact that the large repetition of identical large scale horizontal or vertical blocks in a vast open space tend to produce monotonous environments with resulting unsatisfactory aesthetics, due to the lack or very low visual stimulus produced by the repetition of a great number of blocks deprived of an architectural composition that might be characterized by the ideas of order and visual stimulus. As highlighted by Prak (1985, p.69) "People might suffer from perceptual deprivation if the built environment does not offer them enough variety". Moreover, the open spaces that were left between the blocks also tended to be deprived of any major visual stimulus. It can be noted that many complaints about the lack of variety in modern architecture, particularly in suburbs and office buildings, were made by architects themselves (Prak, 1985). These characteristics of the open spaces also affect the quality of views of people inside the buildings, and so, impoverishing their architectural experience not only outside but inside the buildings too.

Figure 14. Pruitt-Igoe Housing Estate, St. Louis, U.S.A.

Moreover, stimulating visual fields when walking in the cities would be characterized by the possibility of having, at every moment, a different look and not by the look that gets lost in the infinite (Sitte, 1992). This principle can justify the vitality of medieval streets of numerous historic cities and streets in some parts of contemporary cities.

Figure 15. Killingworth Housing Estate, Killingworth, England.

On the other hand, the modernist principles tend to generate monotonous and empty spaces around the buildings (Sitte, 1992). In addition, the ‘traditional’ urban form is generally characterized by buildings with predominantly vertical lines, whereas the ‘modernist’ urban form tends to be constituted by horizontal buildings. In the first case walking seems smaller while in the second case the horizontal lines emphasize and reinforce the perception of greater distance (Gehl, 2010).

Traditional streets and elevated walkways or streets in the air

The walkways between blocks, as in the Killingworth Housing Estate, which reflect the modernist idea of streets in the air and the strict differentiation of functions - the strict differentiation of pedestrian walkways and car-routes, create a pedestrian circulation channel devoid of major sensory stimuli, deprived of visual supervision from people in the housing units and from pedestrians and people in public or private transport. Additionally, the vertical access to the walkways is destitute of visual surveillance and access control. Nevertheless, the architect of the project expressed his full conviction in the appropriateness of his design concept:

“In this ‘vertical village’, unlike conventional multistorey flats, which tend to isolate families, the high level streets or decks will encourage the growth of a community without reducing the privacy which everyone wants to enjoy within his own home. The decks will provide safe walking above the roads ... and places where neighbours can meet and talk, or watch children playing in the public gardens below.” (Killingworth Development Group, 1967, in Kellet, 1987, p.7).

On the other hand, substantial evidence to the contrary can be provided:

‘This romantic vision of ‘streets in the sky’ was not merely inaccurate but completely mistaken. In reality the decks had the opposite effect on social relationships and became associated with anti-social behavior and a sense of acute insecurity and fear. No windows face onto the decks which became anonymous semi-public spaces with access through unsupervised common entrances completely open to all – residents and strangers alike. This created a lack of privacy and control which may have encouraged vandalism and crime. Young children could not be properly supervised from the decks which in addition were noisy (with living rooms directly below) and inappropriate for the exposed climate.’ (Kellet, 1987, p.7).

Hence, there appears to be sufficient evidence to support the idea that the streets in the air do not reproduce the traditional urban street. This is characterized by visual and functional connections between buildings and public open spaces, allows the perception of activities in adjacent buildings and in the public open space of the street itself, tends to be provided with sensory stimuli (visual, olfactory, aural) and to allow visual monitoring from people in adjacent buildings or in the street itself.

Wayfinding in the ‘traditional’ and in the ‘modernist urban form’ and building access

As stated by Passini (1992, p.159) ‘Wayfinding is an important aspect of environmental quality.’ and ‘... wayfinding is a fundamental key to environmental appreciation, be it at the level of architecture or at the level of urban and natural landscape.’ The ‘traditional’ urban form tends to be legible and make wayfinding easier since people move following the streets and access buildings directly from the public space of streets. On the other hand, in the ‘modernist’ urban form wayfinding is generally made more difficult due to the lack of direct connection to the building entrance from the streets and to the great repetition of identical blocks. Moreover, as exemplified by the Guajuviras Housing Estate, the lack of legibility, due to the expressive number of repeated four storey blocks of flats without greater formal distinctions and to building entrances away from the streets, can be made worse when the communal open spaces

do not have a clear definition and control and are disorderly occupied by illegal buildings, such as garages, that tend to narrow and hinder the circulation among the blocks, change the space hierarchy and estate appearance, and negatively affect accessibility and wayfinding in the housing estate (Reis and Lay, 2012).

The idea of ‘urban fabric’ and ‘urban object’

The idea of ‘urban fabric’ is defined by the whole of identical or similar buildings, while the ‘urban object’ stands out, contrasting with the ‘urban fabric’ and generating visual stimulus, focus of attention. The idea of ‘urban fabric’ and ‘urban object’ tends to be clear in the ‘traditional’ urban form (In historic cities or historic downtowns most private buildings, including housing, tend to characterize an ‘urban fabric’ whereas public buildings such as churches and city councils, tend to characterize an ‘urban object’). This relationship between ‘urban fabric’ and ‘urban object’ tended to be a well orchestrated one, with the object creating a focus of visual attention from time to time, and making the urban experience an aesthetically stimulating and rewarding one. Nonetheless, these relationships tend to be lost in the ‘modernist’ urban form where the ‘urban fabric’ tends not to exist, since neither the perimeter block nor smaller buildings facing the street are present. In addition, the ‘urban object’ tends to be isolated from other buildings that are neither part of ‘urban fabric’ nor are ‘urban objects’. Therefore, in the ‘modernist’ urban fabric the idea of designing the urban space and its elements, establishing a relationship between them, the proper idea of urban design, is lost in favour of focusing on individual buildings standing out or not as ‘urban objects’.

Distance between buildings

In a ‘traditional’ urban form buildings tend to be near to each other (since most of them are connected through side walls) and to define open spaces that generally are not so large as to generate huge sunny areas and to make walking uncomfortable during summer. On the other, in a ‘modernist’ urban form, as in many university campuses and residential areas of Olympic or Pan-American Games, the distances between the buildings tend to be big enough to generate huge sunny areas and to make walking uncomfortable during the summer. Moreover, these distances tend to weaken the use of open spaces, since such use is not supported by nearby buildings activities, and to make walking a less enjoyable aesthetic experience than in the ‘traditional’ urban form, where such experience is stimulated by the presence of nearby buildings facades and uses.

Conclusion

These discussions about ‘traditional’ and ‘modernist’ urban forms and some of their implications for the use of urban spaces have emphasized the differences between these two concepts of urban form. These differences show that the ‘traditional’ urban form tend to better respond to urban user needs than the ‘modernist’ urban form. Exemplifying, the relationship between buildings and urban open space, type of building use and amount of buildings’ visual and functional connections with the public open spaces tend to contribute to the vitality of urban life in the ‘traditional’ urban form, to the presence of people in open urban spaces, whereas in the ‘modernist’ urban form these contributions are generally lost. As mentioned by Gehl (2011) people attract people, and having a choice of walking on a deserted or on an animated street, we would generally choose a lively street. The fact that urban experience tend to be much richer in the ‘traditional’ than in the ‘modernist’ urban form, is a major difference between these two approaches to urban form. As emphasized by Rapoport (1977, p.208): “The many

environments in different areas, eras and cultures which are liked and preferred have one thing in common: they all seem to be perceptually interesting, complex and rich.”. The main outcomes from these discussions emphasize the need for a better understanding regarding the implications of urban form for the use of urban spaces, and so, concerning the implications of adopting the ‘modernist’ urban form.

Application of morphological concepts to characterize German immigration's nucleus in Brazil

Bruno Andrade, Elisa Taveira, Renata Almeida

Heritage and Development's Laboratory, Architecture's Department, Universidade Federal do Espírito Santo. E-mail: patrilabufes@gmail.com

Abstract. *This article seeks to analyze comparatively morphological structures as a result from German immigration's occupation in Espírito Santo, from middle XIX century. For this investigation, Gunter Weimer's advanced studies it's assumed as reference, concentrated in the decades of 1970 and 1980, about German architecture in Brazil's southern region. Weimer (2005) is elected because he's a Brazil's central reference about the approached theme. The intention is to recognize and present by mappings some morphological configuration's particularities of urban sites located in espirito-santense's centro-serrana region; occupation structured by hydrographic basin from Santa Maria da Vitoria's and Jucu's river. It is recognized, at the territory's physical-geographic dimension, both the adoption of river courses as structuring elements of land division and the sites' location at high and cold lands. In the urbanistic dimension, there are two types of nucleus: Strassendorf, urban form structured by a central and commercial road; and Angerdorf, urban form when the central road widens open to a square.*

Key Words: *Urban form, German immigration, Espírito Santo/Brazil*

Introduction

This article investigates morphological structures sedimented by German immigrants' occupation in Espírito Santo, from the mid-nineteenth century. For this analysis, Gunter Weimer's advanced studies it's adopted as reference, focusing on German's urban morphology and its deployments in the occupation of Germany's immigrants in Brazil. The intention is to recognize and represent, through photographs, diagrams and mapping, morphological configuration peculiarities of urban sites located in Espírito Santo's central mountainous region, and the occupation structured by river basins of Santa Maria da Vitória and Jucu, in Santa Leopoldina, Santa Maria de Jetibá, Domingos Martins and Marechal Floriano (Figure 1).

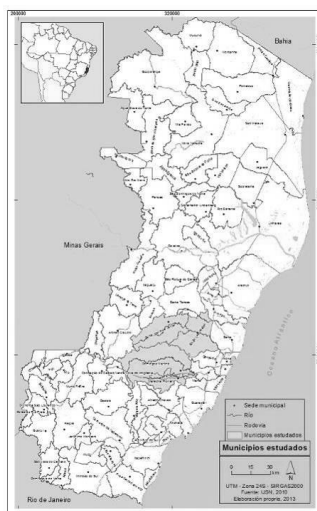

Figure 1. Municipalities' location of Santa Leopoldina, Santa Maria de Jetibá, Domingos Martins e Marechal Floriano. Source: Elisa M. Taveira.

It is recognized, in the territory's dimension, both the adoption of courses of rivers as structural elements of land parceling, as the location of settlements in high and cold lands. In urban dimension, it is identified three types of nucleation: *Strassendorf*, urban form structured by central trade route; *Angerdorf*, urban form that the central trade route widens open to a square; and *Haufendorf*, urban form derived from a spontaneous growth.

The identification initiates from the state of the art, referenced in Weimer, from which studies conducts to German researchers, experts in the urban form's history of villages built in ancient Germania. These represent the effort of human groupings' characterization and systematization originated from times long lasting, related to Northwest European Space's cycles of territorialization.

The historical data's methodology survey and the current cartography's construction for the cities analysis are based on the study by Elisa Machado Taveira in the Master Planning's thesis, "*Redescubriendo el patrimonio: revaluating them culturales paisajes Santa Leopoldina*," under Joaquín Sabaté Bel's mentorship, Professor at the Universitat Politècnica de Catalunya, under development.

Gunter Weimer's advanced studies

Weimer (2005) presents Germany's sedimented morphological characteristics, from two German authors' investigations, Werner Radig²¹⁴ (1955) and Heinz Haushofer²¹⁵ (1974), as analytical subsidy for German occupation's in Brazil, especially in Rio Grande do Sul. This publication leads and guides this article's analysis, in analogy to German immigrants' urban nucleus occupation in Espírito Santo.

In Europe, in the early nineteenth century, in regions where farmers are free, the property is limited to a small land's glebe within the village, encompassing home and garden - a *Hof* - and the land's remainder, forests and pastures, joint exploration. Each parcel is subdivided into arable zones - a *Felder* - and each farmer is entitled to one, in three parcels (Willems, 1946 p.327-328, cited in Weimer, 2005, p.37). The medieval villages' formal evolution varies according to socioeconomic regional logics. The simplest way is the *Weiler* (Figure 2), a set of two or three *Hof*, called *Einzelhofsiedlung* if it's isolated from each other.

Figura 2. (a) A Weiler's scheme. Source: Weimer (2005, p. 41); (b) French Weiler, composed by four sites. Source: Radig (p. 86, cited in Weimer, 2005).

If the *Weiler* grows irregularly, it's a *Haufendorf* (Figure 3), which is the most common village form in *Hünsrcück*²¹⁶. If the *Weiler* develops along a street, it's called *Strassendorf* (Figure 4), commonly found in the *Westphalia*²¹⁷. When the street widens open in the village's

²¹⁶ *Hünsrcück*: region between the Moselle and Nahe's rivers, in Germany, where comes more than half of Brazil's German immigrants. Weimer, 2004, p. 58.

²¹⁷ *Westphalia*: northwestern Germany region, from where comes about 20% of Brazil's German immigrants.

middle road, forming a public place (in the original sense, public passage for cattle), it's an *Angerdorf* (Figure 5). An *Angerdorf's* variation is the *Rundling*, where the street leads to the village and ends in a *devesa* (Latin *defensa*, enclosed property), it's the most common form of Elbe's east settlement, where is located Pomerania²¹⁸ (Figure 6). There are also other settlement's forms, such as *Punkdorf*, *Hufendorf*, *Zeilendorf*, *Waldhufendorf*, *Marschhufendorf*, *Rundweiler* and *Streuselung* (Radig, 1955: 95-96 cited in Weimer, 2005, p 41 -42; Redensek, 2007)²¹⁹.

In consonance with Weimer (2005), Wolf (1926, cited in Redensek 2007), defines the small villages kinds: *Angerdorf*, where houses are arranged around a green space or Anger; the *Strassendorf*, where a central street is the characteristic axis; the *Rundlingdorf*, where houses are arranged around a central green space, and whose radiation is outsourced; and the *Reihendorf*, whose implanted houses are aligned.

For illustration's purposes, Mattedi (2009) argues that this occupation refers to the traditional northern and eastern Germany urban form model, where originates the majority of Brazil's German immigrants, and to Espírito Santo, as the Lubeck city (Figure 7), dated 1143, whose morphology is molded around a commercial axis with roads that connect with the countryside. According to Peluso (1991, p.392, cited in Mattedi, 2009), the cities plan from German colonists is thus described by the urbanist Bernoulli:

The city must be safe over a mountain's back or protected by a river; must have a market, a long and wide main street that reaches a large square in the center. It's streets' system should be understandable at first sight ... The church with its cemetery should be separated from the traffic, but so that the largest nave and the bell tower, emerging from the housetops, dominates the main square.

Figure 7. Strassendorf, characteristic urban form. Lubeck. Source: Mattedi, 2009.

Therefore, the German's colonists sedimented in Brazil urban form is synthesized up in the following way.

The next item is dedicated to characterizing the morphology of four urban settlement experiences, deriving from the German immigration in Espírito Santo's solo process.

Urban form characterization. Experiments in German immigrants nucleus constituted in Espírito Santo / Brazil

The German immigration to Brazil begins in 1824, with the arrival of the Dutch ship *Argo*, to Rio de Janeiro (Seide, 1980), bringing 251 colonists destined for São Leopoldo, Rio Grande do Sul, and 29 men for the Brazilian army, recruited by the German Georg von Anton Schäffer. Besides Rio Grande do Sul, the Germans occupied Santa Catarina and Rio de Janeiro. With the success of these colonies, in 1855, Pedro II idealizes the foundation of German colonies in Espírito Santo (Figure 8). According to Schwarz (1992, p.2), in 1855, it's founded Suíça, a colony in the river Santa Maria da Vitória waterfall region, with an area of 567 km², consisting of equal lots of 62,500 *braças quadradas*²²⁰. In 1857, it was installed 99 Swiss, 24 Hanoverians, 6 Luxembourg, 3 Prussian and 8 holsteinianos (Seide, 1980). Few years after, these are relocated to the site "more fertile and crystal streams cut" (Ferrari, 1968), four leagues below the first installation, which is erected a temporary home for the Cologne's director, warehouses and a shack for housing 50 families. Next to the shack, install traders, builds a chapel, and, by its side, a cemetery, and new buildings for service providers' housing and workplace.

Figure 8. Espírito Santo's european immigration (source: Kill, cited in Posenato, 1997, p.18).

Figure 9, below, illustrates the Topographic Letter of the Espírito Santo's Province in 1878, which is possible to identify the Santa Izabel and Santa Maria colony location, where they are located in the following year, the Santa Leopoldina's colony.

Raises the hypothesis that the colonies' delimitation attends watershed embraced regions: the colony of Santa Leopoldina is referenced by the river Santa Maria da Vitoria; the Timbui's nucleus, linked to the Santa Leopoldina's colony, is referenced by the Timbui river; Santa Izabel, by Jucu river; and Rio Novo, by the Benevente river. For confirmation its analyzed cartographic documentation (Figure 10) and secondary data, emphasizing the interest in establishing the immigrant in place close to watercourses, besides the subsistence factor (Schwarz, 1992; Posenato, 1997).

²²⁰ A measurement lot area unit adopted in Brazil in the nineteenth century, with no equivalent measure for the English language.

Figure 9. Espírito Santo's colony map detail, 1878 (source: Arquivo Nacional, Rio de Janeiro).

Figure 10. Espírito Santo's colony map detail, 1866 (source: Arquivo Nacional, Rio de Janeiro).

The Seyferth's research (1988, p.4 and 5) is in consonance with Ferrari (1968), to inform that in Espírito Santo, such as Rio Grande do Sul and Santa Catarina, the German colonization focus are the upper valleys of the Jucu and Santa Maria da Vitória rivers (mountainous region called *cold lands*). In the upper river Santa Maria valley, there is Pomeranians predominance although the first colony, Santa Isabel, 1847, has been founded by Hesse and Hunsrück immigrants. Seyferth (1988) also emphasizes the German immigration importance as a sociological and historical phenomenon, by constituting a diverse society from the national. Regarding the context of Brazil immigration, the Germans stand out by establishing in homogeneous and compact areas, modifying the agrarian structure and rural life.

Until the mid-nineteenth century, Espírito Santo is one of Brazil's most backward provinces; this fact was mainly attributed to serving as a natural barrier for Minas Gerais gold protection. For such, the Portuguese Crown allows only the coastal belt occupation, restricts navigation and prohibits clearing of the interior (Posenato, 1997). Later then, by the very mountainous regions weather conditions, occurs non Lusitanian immigration, given the Imperial Government program, in the need to occupy the interior lands (Schwarz, 1992). The first colony begins in 1812 with the official creation of Santo Agostinho colony (currently Viana, in Grande Vitória) where arrives 250 Azorean, between 1812 to 1814 years.

The German colonists in Espírito Santo founded two colonies: Santa Isabel, 1847, originating Domingos Martins and Marechal Floriano cities; and Santa Leopoldina, 1857, yielding Santa Maria de Jetibá and Santa Leopoldina cities (Posenato, 1997). Most Germans, both in Santa Isabel as Santa Leopoldina colony, live in dispersed sites in family-colonies, and only a few merchants and artisans families concentrated in the urban nucleus (Table 1) (Muniz, 2009).

Table 1. Dados relativos às Colônias de Santa Isabel e Santa Leopoldina / ES

Colony	Foundation date	Colonists quantity	Predominant foreign nationality	Urban nucleus
Santa Isabel	1847	753	German and Pomeran	Domingos Martins
			German and Italian	Marechal Floriano
Santa Leopoldina	1857	1065	German	Santa Leopoldina
			Pomeran	Santa Maria de Jetibá

Recent picture	Weimer's scheme
Aerial photo	Local urban form scheme

Santa Isabel Colony

Domingos Martins

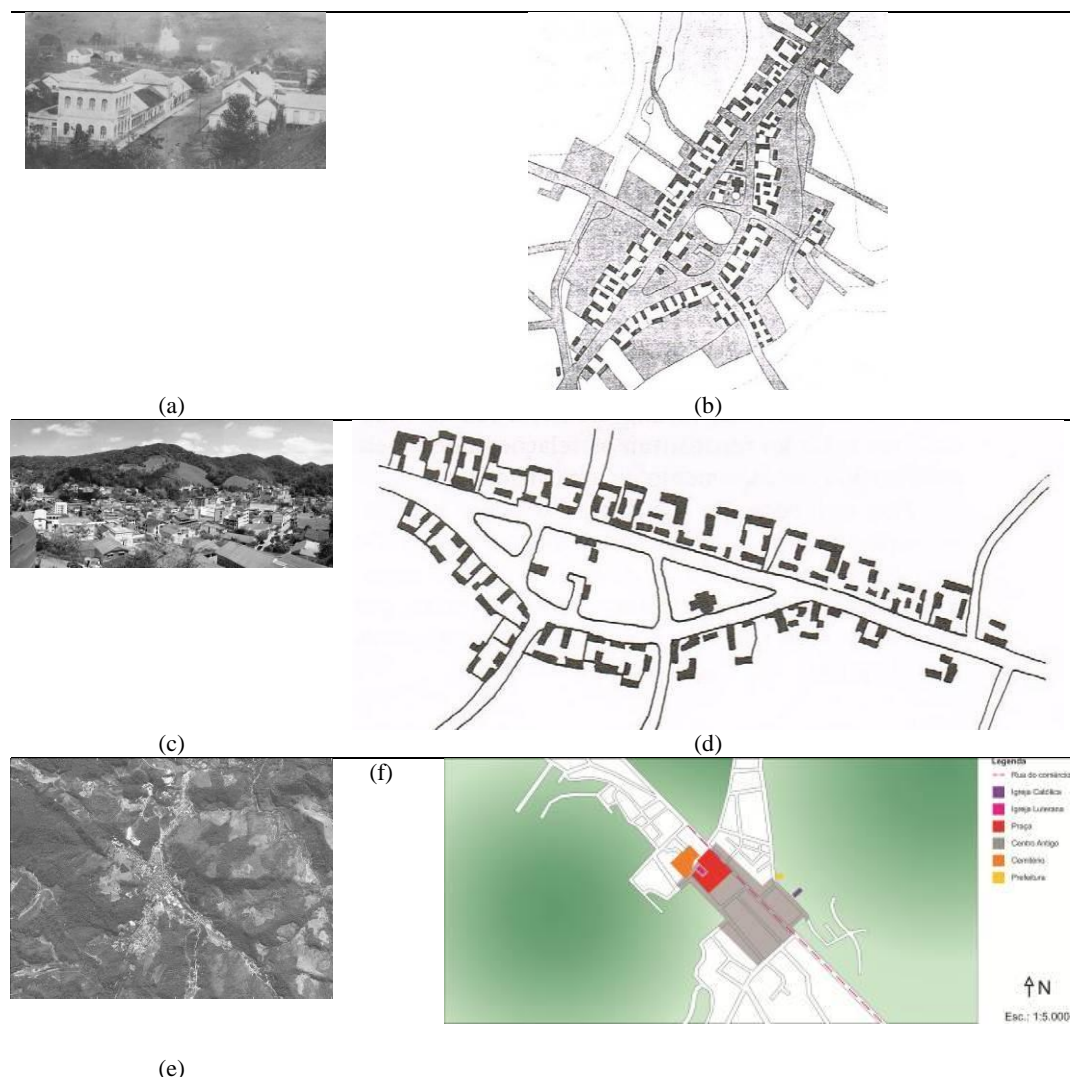

The first Germans coming from the *Hunsrück, Rhenish Prussia*, in particular the *Koblenz, Lötzburen* and *Traben-Trarbach* cities arrive at Espírito Santo's capital on December 21, 1846. Remain a few days in Vitória, and then follow to Santa Isabel colony, first founded colony, by Dr. Luiz Couto Ferraz, President of the Espírito Santo's Province. The colonist moves up the mountain along the Jucu river northern arm margin and settled on January 27, 1847, in Serra da Boa Vista. There are 39 families, 16 Evangelical-Lutheran, and 23 Catholic, totalizing 163 people.

The first chapel is soon built on the Boa Vista's hill where it also intends to build a village. Over there remained about 10 years. Some of the immigrants, for climate reasons, rise higher, and then that Catholic families settle in Santa Isabel and the Lutheran pursue a little more, reaching a flat spot among the mountains which they called Campinhoberg – Morro do Campinho. In 1852 the first Catholic Church is consecrated in the Santa Isabel village. Between the years 1858 and 1860, in Campinho, Lutherans begin their temple construction. First, however, build a small chapel in the area's center where the cemetery is located today.

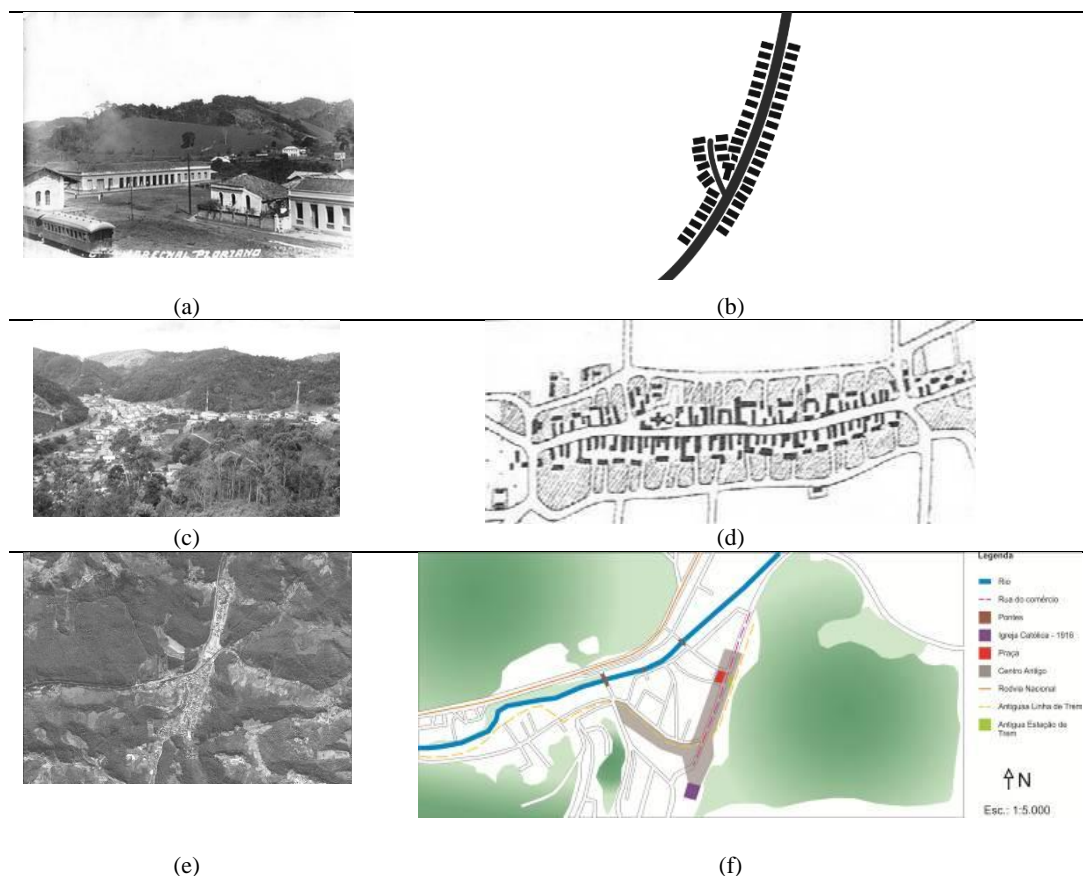

The Colony gradually progresses and then emancipates Viana; being elevated to the status of *Freguesia*²²¹ in 1869. On October 20, 1893, the Santa Isabel municipality dismembers from Viana. Its installation takes place in Campinho, on December 19 of the same year. On December 20, 1921 the municipality's name changed to Domingos Martins, in honor of Espírito Santo's hero, Domingos José Martins.

Next, in Table 2, presents hallmarks references synthesis of Campinho's urban form map.

²²¹ Freguesia is a political administrative category adopted in Brazil, in the nineteenth century, similar to a Municipality, with no equivalent for the English language.

Table 2. Campinho's Urban form – *Siedlung*.***Marechal Floriano***

After the first German immigrant's arrival and installation on demarcated lands in Santa Isabel and Santa Leopoldina colonies, in 1860, the Agriculture's Minister ordered the demarcation of 100 new lots in the Jucu's region, belonging to Santa Isabel colony, and the construction of a bridge over the southern arm river, which crosses the municipality. Thus, in 1862, it's inaugurated the Southern arm village, occupied by the new German immigrants arriving to Espírito Santo, and later, also by the Italians. On May 13, 1900, the village is named Marechal Floriano in honor of the 1st Republic's Vice President, Marechal Floriano Peixoto. On October 13, 1991, Marechal Floriano is emancipated from Domingos Martins. In addition, next, the Table 2 presents hallmarks references synthesis of Marechal Floriano's urban form map.

Table 2.1. Marechal Floriano's urban form – *Siedlung*.

Santa Leopoldina's Colony

Santa Leopoldina

On December 15, 1855 a resolution establish the Santa Maria's river waterfall region as a foreign colony. Originally marked an area of 567 km². In the year 1857 come to the colony the first 140 Swiss German language colonists, and in the following year 222 people of various nationalities such as Germans and Luxembourgers and then Tyrolean²²².

The land's implantation is given by the valley bottoms with front to the river and back to the hill. Unlike the German tradition in which farmers live in small towns, the colonists are distributed at sites in the valley bottoms, in a dispersed linear occupation²²³.

The Santa Leopoldina colony begins in 1857, with 222 German settlers in Porto do Cachoeiro Santa Leopoldina village, where a river port works. Each family gets a lot of 62,500 *braças quadradas* of land (about 190.000 m²). Into the nucleus settlement are reserved 500,000 *braças quadradas*, with plazas, churches, schools, with urban lots of 10 fathoms in length by 25 background (about 22 meters in length by 55 meters deep), with cemetery located outside the village (Muniz, 2009).

Source: <<http://www.ape.es.gov.br/imigrantes/html/historico.html>>. Access 11/20/2012.

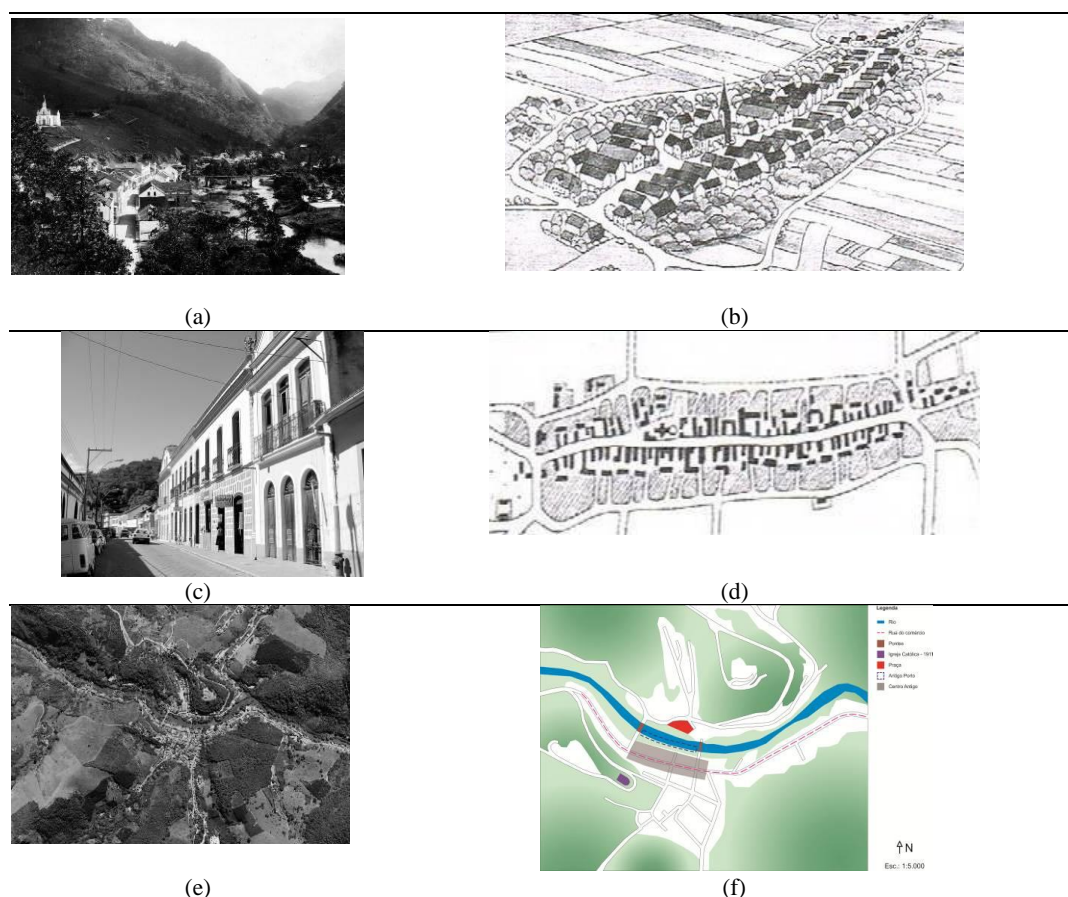

²²³ Espírito Santo (Estado). Relatório da Análise da Proteção do Ambiente Cultural de Santa Leopoldina. Vitória, Secretaria de Estado da Cultura, 2008.

Subsequently, other immigrants arrive: the Dutch established between the years 1857 and 1862; Austrians and Luxembourgers are established in 1857; Germans arrives in 1859, most from Prussia, Saxony, Hesse, Baden and Riviera. Most Pomeranians established between the years 1872 and 1873; while the Italians begin to settle from 1875; but most of it direct to Santa Teresa municipality. The Cachoeiro Santa Leopoldina Village emancipates on June 6, 1882 and Law No. 21 of April 4, 1884, elevates the colony to the status of municipality.

In the figure “a”, in Table 3, there is Santa Leopoldina urban nucleus developed around the commerce street, "back" to the Santa Maria da Vitoria River, due to the location of the port flowing coffee to the coast; and a restricted occupation on the opposite margin, endowed with limited flat area (Figure f, Table 3).

Next, the Table 3 presents hallmarks references synthesis of Santa Leopoldina’s urban form map.

Table 3. Santa Leopoldina urban form – *Siedlung*.

Santa Maria De Jetibá

In May 1873 landed at the Vitoria port hundreds of German families, mostly coming from Pomerania, then belonging to Prussia and now Poland territory. First comes 413 Pomeranians, and also in the same month, comes more 366 Pomeranians, all Lutherans, a people who lived isolated between Germany and Poland, with extremely different cultural habits from the rest of the population.

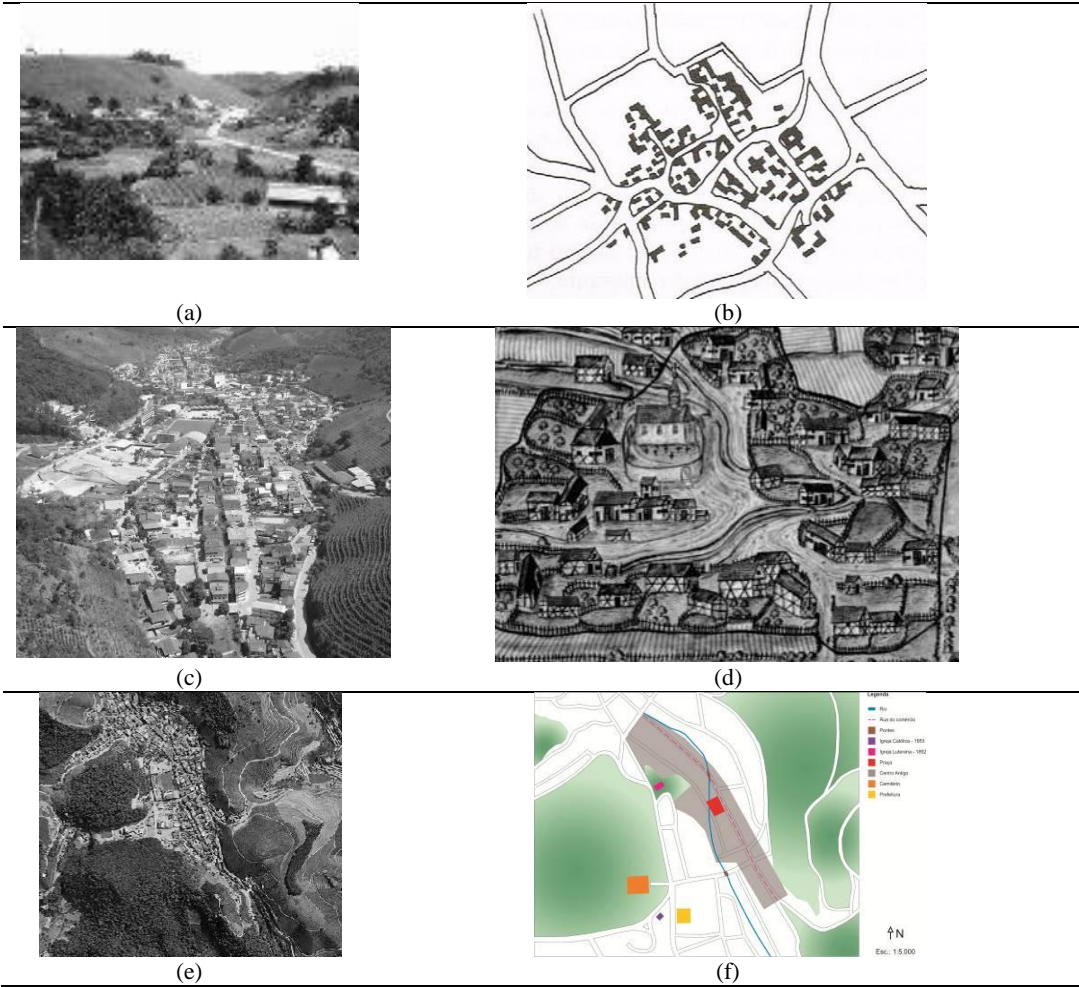

Although not considering themselves Germans, Pomeranians immigrants are treated as such and sent to the mountains top, in Santa Leopoldina’s colony, where other German immigrants had settled. Most Pomeranians settles in regions still called Luxembourg and Jequitibá, in Santa Leopoldina colony. In the following decade, some of these immigrants leads to Santa Maria de

Jetibá region, but among them there are also immigrants from Luxembourg, Netherlands, and the *Rhine* and *Hessen* regions, in Germany, which thus initiate a second stage of the immigration process. Until 1943, the town is known as Jequitibá, being a Cachoeiro Santa Leopoldina's district. By state law no. 4067 to May 6, 1988, the district is elevated to municipality with the current name of Santa Maria de Jetibá.

The Santa Maria de Jetibá's nucleus implementation follows the *Strassendorf* logic, as identified in Santa Leopoldina. However, instead of developing surrounding a street, develops around the São Luis river, Santa Maria da Vitória's tributary (Figure a, Table 4), because the flat valley area allows the occupation to the hillsides limits (Figure b, Table 4) (Weimer, 2005).

Next, the Table 4 presents hallmarks references synthesis of Santa Maria de Jetibá's urban form map.

Table 4. Santa Maria de Jetibá's urban form – *Siedlung*.

Urban Nucleus Form Constituted by German Immigration. A Comparative Matrix

The comparative analysis indicates a *Strassendorf* predominance, identified as main morphological characteristics in the colonies settlement of German dominance, or its variation, the *Angerdorf*. The territory physical dimension is recognizable both in the adoption of rivers courses as structural elements of the land's division, lots located along watercourses, generally orthogonal to the water frontline; as in the settlements location in high and cold lands. Despite

the characteristic factor of the immigrant's sediment close to watercourses, it doesn't represent an urban form front role, because the main street is the structuring force line of the settle.

The urban dimension stands out the inhabitancy from nucleation, and the dominance of a structured pathway by a road, generally central and characterized, functionally, by the commercial activity prevalence. The built settle, consisting of peculiar architecture and detached and distant position, distinguished the single central tower church.

From Günter Weimer, the Santa Leopoldina and Marechal Floriano urban morphology analysis allows to recognize the predominance of *Strassendorf* formal type, ie the, urban design structured from a commercial street, main, one of the German colonization in Brazil central attribute. Furthermore, there is a river role in choosing the occupation locus, despite not representing morphology front role.

In Santa Maria de Jetibá, *Haufendorf* is the predominant type, with spontaneous growth characteristics, polygonal shape, decentralized from the Santa Maria da Vitoria tributaries, and may in some ways be considered *Angerdorf* due to the formation of a square during urban area growth. Finally, in Domingos Martins, the predominant type is *Angerdorf*, a variation of *Strassendorf*, in which the central street widens open to a central square.

Conclusion

This paper intends to acknowledge and present the urban areas morphological configuration particularities derived from the German immigration in Espírito Santo. Chronologically sequential, occupations promote urban settlements with more than a few similar characteristics. Importantly, this is an initial approach to German colonization in Brazil urban heritage studies, especially in Espírito Santo experience.

The geopolitical dimension, initially, draws attention to the underlying territorial cutout for the colonies settlement logic: situated in the colonial occupation limits areas in Espírito Santo. This first criteria seems to follow the physical and geographical territory dimension, recognizable both in the adoption of rivers courses as land division structural elements - lots located along water courses, in general, orthogonal position to the waterfront; as the settlements location in high and cold lands.

The urban context stands out the settlement from nucleation, and the structured pathway dominance surrounding a road, generally central and characterized functionally by the prevalence of commercial activity. The built settle, consisting of peculiar architecture and detached and distant position, distinguished the single central tower church, if any.

The urban morphology analysis, from Günter Weimer, in Santa Leopoldina and Santa Maria de Jetibá, in Espírito Santo, presents a *Strassendorf* formal type predominant, ie the urban design structured from a main street, commercial, one of the German colonization central marks in Brazil, in addition, it's noted the river role in choosing the occupation locus, however, is not a protagonist urban form role.

As future deployments, it's pointed out urban morphology related investigations in other immigrants cities (Weimer, 2004) in Espírito Santo; from a deepening in specific literature, focused on Werner Radig, in German language, with the objective of identifying and mapping the immigration nucleus settle in Espírito Santo, from the nineteenth century, territorialized in the Santa Maria da Vitoria and Jucu river basins.

Exhibition of City. The case of Lisbon 1940 vs Rome 1942

Elisa Pegorin

CEAU Centro de Estudos de Arquitectura e Urbanismo / FAUP Faculdade de
Arquitectura da Universidade do Porto, Portugal. E-mail: epegorin@arq.up.pt

Abstract. *In order to exhibit their own dominance, during fascism in Italy and the authoritarian regime of Salazar in Portugal, the respective capital cities, Rome and Lisbon, were to plan an International Exhibition. At a different scale of analysis, the responses of both States to the public space present analogous elements as well as differences, links of continuity however, can be found. Rome and Lisbon have not been arbitrarily cited as example, but chosen because they are directly related through their planned exhibitions. If we do a comparison between the scales of the two cities (Roman occupied an area of about 400 hectares, Portuguese and a much small area), there are similarities between the two like the choice of the place and manner of their integration (or not) in the existing city. Like in Lisbon wanted to bring the city to the Tagus, in Rome Mussolini wanted to bring it to the sea and, in both cases, the urban redevelopment included a change in the road network, as well as the creation of new connections. The aim of this essay is to analyze and understand how both these countries responded to urban issues, summarized in three points: the territorial scale, in this case the degree of connection with the historical city; the organization and exhibition of a "new city".*

Key Words: Exhibition, Estado Novo, fascism, Urban Planning.

Aderire perfettamente alla vita d'oggi, materiale e spirituale, pur rispettando le condizioni di ambiente. Ammettere quanto vi ha di universale, di corrispondente alla civiltà contemporanea, nei movimenti artistici europei, innestandovi le nostre peculiari caratteristiche e tenendo presenti le nostre speciali esigenze di clima. Ecco il nostro compito.¹ (Marcello Piacentini)

During the fascist regime in Portugal and Italy, the respective capitals, Rome and Lisbon, were to plan an international fair (almost at the same time): the outcome of the planning proposals presented both similarities and differences, however signs of analogy and continuity can be found, determined by constant diplomatic and cultural exchanges between the two countries at that time.

The paradigm underlying expositions on this scale implies thinking and building a "new city" inside the City itself: how to design this new part of the town; whether it should be integrated with its present fabric, historical heritage and urban complexity; how it should take into account its past, and the course decided for its future. And furthermore what future will there be for that "new part" inside the historical city? Architecture, as design process developed on a specific period, involves the dimensions of time and space. Thinking a set of pavilions as if they are "ephemeral" or rather to stay and to last, define the urban choices for the urban planning of the compound itself. All this is sublimated in a representative architecture that stands and states a clear ideological choice of those involved.

From the late nineteenth century, and especially in the '30s, the debate about urban planning via the alteration of the historic town with the "modern city" entered its maximum point, and was closely bound to the ideology and propaganda of the specific country.

Ideology and propaganda

In Portugal, along the riverside district of Belém, the exhibition called *Exposição do Mundo Português* was planned for the year 1940; the Italian Exhibition was designed for Rome, for the

year 1942.

Both Fairs had some common purposes; the main one was to represent the valour and strength of the State, under the concept of nationalism in the context of the broader notion of "Empire".

Both Rome and Lisbon intended to assert themselves as capitals of the Empire: the "Roman Empire", so celebrated by Mussolini; and the "Portuguese Empire", that claimed to have given the rest of the world its "Latin civilization" through its homeland extension to its colonies in Africa and South America.

This premise outlines that the two city's expos shared similarities on its urban and architectonic design especially throughout a bond of political and ideological principles that uses architecture (and its image) to demonstrate abroad, the modernity of the country, and at home, national pride celebrating the country's iconic values to the people.

On that matter, the link between Portugal and Italy, was supported by Portuguese government itself by António Ferro (Director of National Propaganda Secretariat) and Duarte Pacheco (Minister of Public Works), senior representatives of the political regime.

In political and ideological terms, Antonio Ferro often looked at Mussolini's regime as a point of reference to shape Antonio Oliveira Salazar home politics: it is widely documented that Portugal studied the background of the Italian political system at that time, identifying affinities with their own national interests and aims, especially after its distancing from the Nazi Germany's ideology after 1939. The Portuguese political reorganization itself, called "Estado Novo", took as a reference many of those political changes that occurred in Italy, such as for example: the juridical reform, corporatism, the FNAT³, educational reform, the AEV and youth organization (*Mocidade Portuguesa*⁴), among other models of political and socio-economic organization.

But if on one hand, the Portuguese government with António Ferro and Duarte Pacheco, always showed great interest in Italian politics, artistic and architectural models, on the other hand Italy itself was keen to share influence and dominion beyond its borders. Many institutions were established in foreign countries (for example, the Caur, the Fasci all'Estero, the Italian Institutes of Culture) to promote

the Italian propaganda abroad. All this boosted and strengthened the Portuguese-Italian connection also in terms of cultural orientations.

Within this framework of political and ideological influences with Italy, the grounds to organizing a "Portuguese World Exhibition" were set. This represented an opportunity to show to the rest of the world, the strength, the grandeur and modernity of the country when simultaneously, as Salazar wrote, "*fosters self esteem of the Portuguese people and remind you of its value as a nation*".⁵

Marking history: the value of time

The ideology behind investments on this scale - the universal expositions of Lisbon (1940) and Rome (1942) – consisted in building an artistic propaganda tool, based on the celebration of each country and their heroic past and present, displaying to the world the modernity achieved from their heritage. Both exhibitions therefore feature significant events of the past history of each country.

In Portugal, on the 20th of February 1929, Dr. Alberto de Oliveira, in an article entitled "1140-1640-1940", published on the *Diário de Notícias*, launched the idea of celebrating the eight hundredth anniversary of the foundation of the country (1140) and the tri-centenary anniversary of the Portuguese Restoration War (1640). However, his proposal was not immediately taken up. Only in 1938, in an "Unofficial Note from the Presidency of the Council", published on March the 27th, on the *Diário de Notícias*, did Salazar declare his intention of celebrating the double anniversary with an exhibition about the *Portuguese World*.

In the same years, in Italy, after the events of 1936 that led to the proclamation of the

Empire, the “Bureau International des Expositions” accepted the Italian application, submitted in 1935, to hold an international exhibition, originally scheduled for the year 1941. In 1937 the final date for the exhibition that was called *Olimpiadi della civiltà* was set for 1942. This date was chosen by Mussolini himself to be representative of the two decades that had elapsed since the establishment of fascism (1922-1942).

The date of the Italian exposition was announced before that of the Portuguese and it naturally provided an example that could be followed.

However, while the development of the Italian exposition “E42” had already been prepared some time before, the planning of the Portuguese celebration was delayed. Salazar, conscious of the lack of time and of the limited economic resources of the country, outlined a short-term plan for the works: only two years to organize the event in a difficult context where the international situation had worsened with the onset of the war in 1939.

The main idea was to make the work express, on one hand, a historical orientation, traditionalist and official, intended to assert Lisbon as the capital of the Empire, conforming the symbolic values of the *Estado Novo*; on the other hand to brand themselves with “Imperial Rome” in its symbolic meaning: the architecture, the relationship with the city, the monumentality, the strength of representative statuary.

The model of Rome

Notwithstanding the influence of the European context at the time, and of German and French architecture, it is pointed out in this paper that the Portuguese exhibition owed most to the relationship with the Italian exhibition.

The reference to Italy was already clear in 1934, at the “First Congress of the National Union,” which was designed as a documentary exposition planned by the architect Paulino Montês, where Ferro proclaimed the “May 28” Movement. One example mentioned was the Italian exhibition held for the celebration of the tenth anniversary of Mussolini’s march on Rome, in 1932. In the Portuguese fair, the attention given to Roman architecture was clearly expressed by the creation of a more modern and rational space, always informed by an awareness of the different scale of the two countries. In an interview with engineer Carlos Santos, comparing the exhibition with the Italian one in 1932, claimed to “feel a disappointment, because it is at the scale of the country, but ten times smaller”.⁶

Following the Italian 10th anniversary exhibition: “*Mostra della Rivoluzione Fascista*”⁷ in 1932, Portugal celebrated in 1936, the tenth year of the National Revolution. The Portuguese exhibition had to deal with similar spatial problems to those in Italy, especially regarding fitting the desired design layout within the existing environment. The solution involved, as it had done in Rome, combining ancient architecture with a monumental structure with straight and rational lines “and, despite the considerable difference the way in Italy and Portugal solved the same problem, we had learned something from the Rome exhibition”.⁸

Besides the exhibition of 1932, following chronologically, the Milan Triennial of 1933 and 1936, reported in national and international journals of the time. were also known amongst Portuguese architects

Simultaneously, we must not forget that Portugal had participated in other exhibitions, such as Italy: Paris 1937, New York and San Francisco 1939; which were important to consolidate the image of the *Estado Novo*, used as an opportunity to experiment with the pavilions a new representative architecture with the aim of asserting the identity of the state. The 1937 exhibition in Paris was certainly a significant one for Portugal. In this same exhibition wide visibility was also given to the Italian pavilion designed by architect Marcello Piacentini, as shown by the repeated publication of this work in *L’Architecture D’Aujourd’hui*⁹, an international journal which arrived in Portugal, impressing (their) architects.

At the time, architecture and monumentality of Italian contemporary works were clear references for the Portuguese architects, many of whom had travelled to Italy, staged or

collaborated with Italian architects. These contacts are documented in the state archives and private archives of these architects, where there are many surveys, photographs, books and Italian magazines.

The plans for the new fair in Rome, were published in the magazine *L'Architecture d'Aujourd'hui* few months after the proclamation of the intention to prepare a Portuguese exhibition, precisely in the issue number 10, October 1938¹⁰. It is interesting that, later in 1940, a special issue (from the same magazine) "Expositions"¹¹ presents simultaneously the two exhibitions: "Rome 1942" and "L'Exposition de Lisbonne 1940".

Press and magazines were the main vehicles for the diffusion of the plans of the Roman exhibition, named with the initials of E42 (after the war renamed EUR¹²) (Fig.01). There, the project was widely documented since its presentation in 1937, first by the Italian press, then reissued later in the main Portuguese magazines: *Arquitectos*, *A Arquitectura Portuguesa e Cerâmica e Edificação*.

Figure 1. Plano of the E42, Rome, 1937-'42 (source: Tafuri,M., Dal Co, F., *Architettura Contemporanea*. Electa, Milano 1976, p.260).

In 1937, in Rome, Marcello Piacentini was appointed as chief architect of the E42. In Lisbon, two years later, 1939, the architect Cottinelli Telmo was nominated as director for the Portuguese expo. Their relationship was close. Mainly because, at the time, Cottinelli Telmo was also director of the Portuguese magazine *Arquitectos* (magazine of the National Union), where he had, as a correspondent from Italy, Plinio Marconi¹³, Piacentini's collaborator. Plinio Marconi had already represented Portugal before, at the General Assembly in Paris on 1937, covering for Pardal Monteiro - one of the most influent architects of the urbanism of the *Estado Novo*, the latter also involved in the exhibition in 1940.

Cottinelli Telmo himself, while director of the union's magazine, had first-hand access to the foreign magazines¹⁴, many of them from Italy: *L'Architettura Italiana*, *Casabella*, *Domus*, *Edilizia Moderna*, *Rassegna*, *Architettura Rivista del Sindacato Nazionale Fascista Architetti*, which began publishing the Roman exhibition since 1937¹⁵. It is essential to know that, among the most important documents from Cottinelli Telmo's library, there is the volume *Exposição Universal De Roma 1942-XX*, which includes the paragraphs: "program", "General Rules" and "Invitation to the World", with drawings, photos of the model and the expo buildings

(Portuguese edition of 1938).¹⁶

It is likely too, that rumours of Italian exhibition reached Portugal with the help of the architect Giovanni Muzio who was called to Portugal in 1939 to replace Marcello Piacentini working with the Municipality of Porto, when he took over the responsibility for planning the E42.

In the same year of 1939, with the construction of the exposition in Belem already started, the Roman magazine: *Civiltà: Rivista dell'esposizione universale di Roma*¹⁷ . arrived in Portuguese universities. The presence of this magazine in the Portuguese universities is not surprising considering the diffusion of Italian propaganda abroad, one of the pillars of foreign politics for Mussolini.¹⁸ In those years, it is important to remember that those involved in the Belem exhibition had already travelled to Italy. For example, in 1939, Adelino Nunes, returned to Portugal with the most important books of Italian architecture of the time, during the time he was planning the Post Office building of the Belem expo. Also the artists who played a key role in representing the monumentality (Fig.02) had had a connection with Italy: Leopoldo de Almeida, for example, considered the main sculptor of the expo, author of the *Padrão dos Descobrimentos* (along with Cottinelli Telmo) had worked in Italy for three years, having performed in Rome a solo exhibition of his work.

Figure 2. Photo of Exposição do Mundo Português.

In 1939, a book by Gustavo Giovannoni arrived in Portugal called: *Lineamenti fondamentali regolatore del piano di Roma Imperiale*, with 12 panels of drawings.¹⁹

On the other hand, Italy also asked the Portuguese National Committee for the Centennial, an appropriate space reserved in one of the pavilions of the Portuguese World Exhibition as well as at the inaugural act on July the 1st. Previously the Chief of State and members of the Portuguese Government, Admiral Umberto Monico spoke on behalf of the Royal Navy of the Italian Empire, marking the connection of Italian and Portuguese empires. To honour the country, the Italian magazine *Architettura* reproduced some photographs of Portuguese exhibition, with the following commentary: "Excellent examples of good architecture well suited to its function".²⁰

If we put aside the comparison between the scales of the two expositions (the Roman one occupied an area of about 400 ha, while Portuguese a much smaller one), there are similarities between the two regarding the issues that arise when planning an event of such scale: the choice of the place and the way of its integration (or not) with the existing city.

In Portugal, the coordinators of the exhibition - Júlio Dantas, Augusto de Castro and Antonio Ferro - who had the responsibility to present "the true city of Portugal's history", after some doubts about the place, decided its final location to be in Belem, with the pavilions organized around the garden in front of the Jeronimos Monastery.

The site is a flat terrain, relatively far from the city centre, surrounded by notable pre-

existences and at the time partially occupied by some warehouses which were demolished, but which allowed the integration of the Tagus river within the exhibition as a key element to achieve the historic character required (fig. 03). Another aspect considered in Lisbon, was the integration of the city's main historical elements with the very site of the expo through light effects. The castle of *São Jorge*, the monument to the Restorers and *Liberdade* Avenue, geographically isolated poles of the city were connected with Belem using electric light beams. A scenic ensemble, full of symbolic sense, to be seen by the river.

Figure 3. Site plan of Exposição do Mundo Português (source: Guia da exposição do mundo português, Lisboa, 1940).

In Rome instead, a completely empty lot was chosen. Far from the historical city centre, unrelated to the rich architecture of Roman antiquity, and thought to be planned together with a new road axis linking Rome to the sea. A "fourth" Rome. Lisbon wanted to bring the city to the Tagus, and Mussolini wanted to bring Rome to the sea. Whatever the goal, in both cases, the urban redevelopment included a change in the road network, as well as the creation of new connections.

Figure 4. Aerial view of the portuguese exhibition in Belém, 1940 (source: Eduardo Portugal, 1940, Arquivo Fotográfico CML).

Regarding the spatial distribution of each plan: The kernel of Roman exhibition was a square crossed by a road leading to the historic city; in the Portuguese case, the axis that structure the whole layout is constituted by the river and a main square, interconnected with the elaborate presence of the *Jeronimos* Monastery. Thus was born the Empire Square, bounded on one side by the river, on the opposite by the monastery and on the other two sides by two pavilions: the main ones.²¹ The exhibition was like a "modern" take on the historical city: the new square

designed for the exhibition recalls the Commerce Square of historic Lisbon, reaffirming the Portuguese dominance of the sea in the memory of the discoveries.

Figure 5. Exposição do Mundo Português (source: Guia da exposição do mundo português, Lisboa, 1940).

In the Belem expo, the pavilions (Figure 4) were distributed in a fragmented way, in a relation to the outdoor spaces, where the perspective is not axial, but constantly changing. Water is a key component. As a symbol, it reinforces the historical importance of Portugal in maritime trade. It has architectural potential, in the sense that the water reflects and extends the architecture, supported the pavilions like if were floating boats. The pace of the public space between the pavilions have a hierarchy dictated by voids, on the opposite to what happens in Rome, where the rhythm is given not only by the emptiness but, above all, by the metric and monumentality of the architecture. The buildings design in Rome create a coherent whole, unlike in Belem, where the pavilions were designed with different languages. In Belem a hierarchy of styles was chosen for the pavilions: modern for the most monumental and traditional for the minor ones, arriving even to reproduce "Portuguese villages". This choice was not random. Amplify instead the marked difference within the architecture of the two regimes: on one side the Italian fascism in search of modernity and monumentality; on the other side the ongoing commitment between modern taste and traditional rhetoric, characteristic of the *Estado Novo* (Fig. 05). The Portuguese exhibition also learned from the Italian one to reinterpret the elements of the historical city and use them for its own purpose,: Belem came out as future expansion of Lisbon, when the E42 was intended to be a new, almost independent, block of Rome.

Figure 6. Photo E42, Rome, 2012 (photographer: Alessio Agresta).

Another difference is that, in Rome, the E42 was designed from the beginning to last beyond the exhibition itself, therefore, the architecture features a greater solidity in all aspects: urban

planning, construction criteria and used materials (Figure 06).

The exhibition of Belem was conceived rather to be an ephemeral experience running over a specific period of time. This is reflected in the choice of materials, speed of execution and reduction of costs. Being approved in 1939 and scheduled to run the next year, in Lisbon, the general plan of the exhibition was seen as a test case for future changes inside the city, considering impossible, in the immediate, a definitive urban transformation. As Cottinelli Telmo stated later: the exhibition was intended to show to the world the strength of the state, and the great ability of Duarte Pacheco as Minister of Public Works.

In the preface of the "Exhibition of the Portuguese World guide" the main reasons of that choice could be read: *"For the first time a great exhibition of History was held here. Until today, only international or national fairs for commerce, industry or colonialism were made here. That should be a lesson of energy, a portrait of the Portuguese genius through all their spur of greatness, a balance of spiritual forces. I mean: the exhibition will not be a Museum of dead things, but an example and an exaltation of the permanent and immortal forces of our nation"*.²²

Clearly this is an ephemeral architecture. That was clear to Salazar and to the architect chief Cottinelli Telmo, when he said: *"the ephemeral architecture is a kind of adventure within the architecture"*²³. Among the objectives to be launched for the future, not an archaeological demonstration looking at the past was pursued, but rather *"whether it's fair or exhibition of every nature, architecture always look forward and participates in the spirit that exists in the composition of advertising. It is always a manifesto"*²⁴. The important thing was to show (off).

The pavilions were built as ephemeral elements, but even so, Cottinelli Telmo was convinced, based on the E42, that what will last is *"a preparation of a vast urban plan,"* and that the exhibition was *"a dress rehearsal of the first International Exhibition to be held in our country"*. Was fully clear, the desire to be first and foremost a "Symbolic City" that *"will be in the shadows of the storm of the current world, the document of national consciousness and faith with, strong of a glorious past that celebrates, the Motherland affirms the unwavering certainty of the Future."*

Figure 7. Photo of the Palazzo della Civiltà, 2012 (photographer: Alessio Agresta).

Comparing the urban choices, the architectural languages of the pavilions, Rome (Fig.07) and Lisbon were both trying to rebuild their own classicism.

Voluntarily, Portuguese architects, choose to be never completely away from tradition. Always leaving - even in the most "modern" cases - a reminiscence of vernacular identity: so in the most obvious cases there is always an element that refuses to be merely trendy to be "modern and Portuguese ", fulfilling so the primary mission requested by the *Estado Novo*. So says Augusto de Castro, General Commissioner of the Exposition: *"It has been demonstrated*

that it was possible to elevate life and national consciousness to a level unanimous understanding and an environment of collective elevation that many assumed unattainable" ²⁵.

Figure 8. Photo detail of the Palazzo della Civiltà, 2012 (photographer: Alessio Agresta).

The history and development of exhibitions is a complex story and deserves - to be properly understood - a more detailed reading of the various determinants, as well as a careful examination of each pavilion and sculpture (Figure 8). Due to the beginning of the war, we never got to see the full E42 (Figure 9) and, as to the Portuguese World Exhibition of 1940, remain no more than a spectacle offered to the country.

Figure 9. Aerial photo of E42, Roma, 1953 (source: wikipedia).

Integrated Approaches

Although the conference proposals and research papers organised under the theme - 'Integrated approaches' include a wide range of theoretical and practical interests and purposes, they are primarily concerned with urban form analyses and their planning and design implications. The study of urban form relies on the identification and analysis of structural elements or a combination of structural elements of the urban landscape. Different disciplines and professional groups have developed their respective research ideas and concepts for describing and interpreting urban form. For example, architects use building type areas and urban tissue to understand the configuration of urban form; planners and urban designers are concerned with land-use zones, ecological areas and historical precincts. There have been efforts to develop an integrated approach to urban form. In particular, geographical urban morphologists, argued that the urban landscape comprises three morphological elements: the ground plan (comprising streets, plots, and the block plans of buildings); the building fabric; and land and building utilization. The idea of urban morphological regions is a key tool for distinguishing and characterizing urban landscape divisions and the relations between them. Morphological regionalisation can be used as a basis for prescriptions in which future changes are incorporated harmoniously into the existing landscape. Recent research on an integrated approach to urban form includes Swedish researchers' Place Syntax and Vitor Oliveira's *Morpho*. The use of computer tools and integrating physical and socio-economic elements are increasingly important for spatial data analysis and synthesis. Research papers under this theme are expected to contribute to the exploration of urban form analyses which are fundamental for creating and managing urban landscapes.

Study on regeneration of downtown area through infrastructure development as urban catalyst. case study of Tokushima city's regional resource: Shin-machi river's frontage development

Koichiro Aitani¹, Takafumi Arima²

¹Department of Architecture, Texas A&M University, Langford Building A – Room406, College Station, TX 77843-3137, USA. ²Department of Architecture and Urban Design, Faculty of Human-Environment Studies, Kyushu University, Japan

Abstract. *"Urban Catalyst" indicates "Project where the catalyst was applied to stimulate the metropolitan environment for the improvement of an existing city". Conceiving of urban design in terms of architectural actions and reactions, the elements to act as a catalyst are defined physical elements such as buildings, open spaces, and the temporary buildings in various scales, and broadly non-physical elements such as festivals and events could be considered also. In this paper, the downtown area of Tokushima city was chosen as a case study and discussed about the Shin-machi board walk along the River, and its effect to the city. Community has been developed to utilize open spaces along the river. The essence of Urban Catalyst is to create a new space within a city while maintaining an existing context. In addition to that, this method is quite different from the redevelopment such as "Scrap & Build" approach.*

Key Words: Urban catalyst, urban transition, water front, event, management, infrastructure.

Introduction

Background and Purpose of the Research

The decline of the central area in the local cities is brought into discussion for such a long time, but there are some cities with which original regeneration schemes brought their life back, or regained their vitality. In addition, Central City Revitalization Law was revised in 2006, and it pointed out of the needs of "Regeneration Plan underutilization of Local Resources", therefore, the movement of regeneration of the downtown initiated by the local governments or shopping mall's association is quite active recently in nationwide^{1) 2) 3) 4)}.

Recently, the method of urban regeneration, called "Urban catalyst"^{5) 6) 7)}, draws more attentions in Europe and America. In this paper, "urban catalyst" is defined as a catalyst promoting the chain development and regeneration in the city and places it with something like catalyst in the chemical reaction. Unlike the development methods such as "Scrap and Build" in the period of economic growth, it is a significant characteristic of urban catalyst which promotes changes and chain effect to the surroundings beyond the boundary of the development site. It should be an extremely effective method such as Japan, which is in a mature phase, not growing, rather declining and shrinking. The point unlike the conventional development method, urban catalyst make effect to the surrounding neighborhood like chain effect which is the strong characteristic whereas the conventional method limited in the change of the target site itself. There could be lots of examples to be observed as a result of "urban catalyst", even if they are not recognized as is, which exactly influenced positively around its surroundings and most likely regenerate the area.

The central area around the Shinmachi River in Tokushima City is the place where the decline is the big issue. However, it is remarkable that city regeneration advances significantly by the citizen lately, authorities, collaboration of public and private sectors, it would be beneficial to understand the current situations and to find out the physical influence

on to the built environments, clarify the individual activity and its relation to each other, and then applying these knowledge to establish the Japanese oriented urban catalyst theory. At a glance, it seems that there could be a certain rule, regularity, even type or pattern for these successful regeneration exist, even if it happened randomly without any order, or just by accident. Not only restraining indiscriminate developments, but also enabling the selection of the strategic catalyst, and effective places for intervention, envisioning its regeneration, would be effective way of development without spending enormous amount of investigation. Urban catalyst could be an optimize solution for urban regeneration. The objective of the research is to analyze the cause and evidence of declines of the city center, Shinmachi district, and also to clarify the chain effects of catalyst to the urban context, built environments and community development chronologically.

Precedence Research

There are some papers which focused on the Shinmachi River for the research in the past. Those are by Akihiko Higuchi, “Riverfront Development for Community Revitalization”⁸⁾ and by Yoshitomo Deguchi, “Study on Improvement of Shinmachi Riverside Park and its Influence to Surrounding Environment”⁹⁾, and both of them are describing about the role of the urban river in the viewpoint urban design, but most of other research is limited in the engineering aspect such as quality of water resource and construction and maintenance of infrastructures along the river, thereby there are very few research dealt with the collaboration among community leaders, or community development for urban regeneration, or cause and effect related to the related field, moreover the emphasis on the chain effect of the methodology in urban regeneration.

Summary of the Research

Method of the Research

In this research, to obtain a general and background information on the research area (Tokushima City Center), chapter 3 clarifies it based on various documents^{10), 11)} including statistics data and documents about urban transformation. Chapter 4 refers the previous research of the urban transformation and forces on Awa Dance Festival. Chapter 5 focuses on the transformation around the Shinmachi River successively and effects of chain type catalyst around the Shinmachi Boardwalk construction, recent activities by the residents and community, several hearing survey had conducted to the local Government and event organizers to clarify the present conditions and issues. Chapter 6, summaries and analyses each chapter for the establishment of the Japanese type urban catalyst theory.

Summary of Tokushima City and Downtown Area

Tokushima City is developed on a delta located at the mouth of Yoshino-gawa River, and 138 rivers flow across the city, which is quite rich. The most of Tokushima City were located on the Tokushima plains, forming city blocks in a flat part, and the downtown developed between the symbolic Mt. Bizan and the former Tokushima Castle (Figure 1) since 16th century, feudal period.

The core of the central city is constituted with two districts; Shinmachi district and Uchimachi district. Particularly the Shinmachi district was flourished by its port activity, indigo products and sugar are the main trading products, and it became the most prosperities commercial district in Tokushima. However, large commercial districts are concentrated around the JR railway station, and now younger generations recognize the station area is the city center, not the Shinmachi district. This research's study area, Shinmachi River Neighborhood is around the border between Shinmachi district and Uchimachi district.

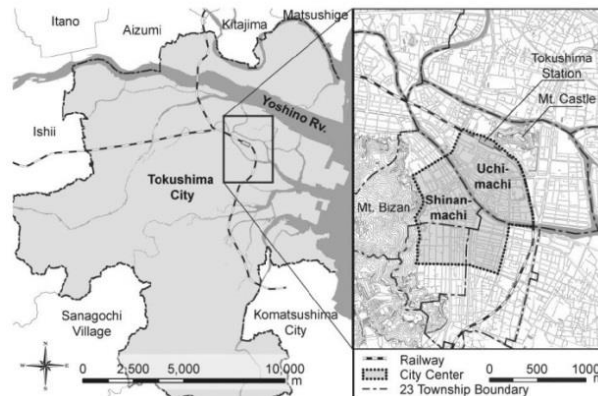

Figure 1. The Shinmachi District located in Tokushima City Center.

Transformation of the City Center

Statistics and maps of about 30 years are collected and these data organized and analyzed for visualization to clarify the transformation of the city.

Analysis by Statistics Data

Statistics data such as national census, establishment company statistics, and commercial statistics are obtained from the Tokushima municipal government office and visualized it. Additionally, 23 administrative sections which Tokushima City was divided into 23 districts, is analyzed, however, as shown in Figure 2, only Uchimachi district and Shinmachi district was visualized, while invested to see the transformation of the city every five years from 1970 through 2005.

Transformation of Buildings (Large Commercial Facilities, Movie Theaters, Parking Lots)

Through visualization of the collected map-data every in five years of Tokushima Center, locations and transformation of the buildings such as large commercial facilities, movie theaters, and parking lots is conducted. Based on Z-map of 2009, Zenrin map information is plotted on the GIS map with every 5 years and the plot area of the parking lots is calculated particularly to verify the urban transformation on GIS (Figure 2).

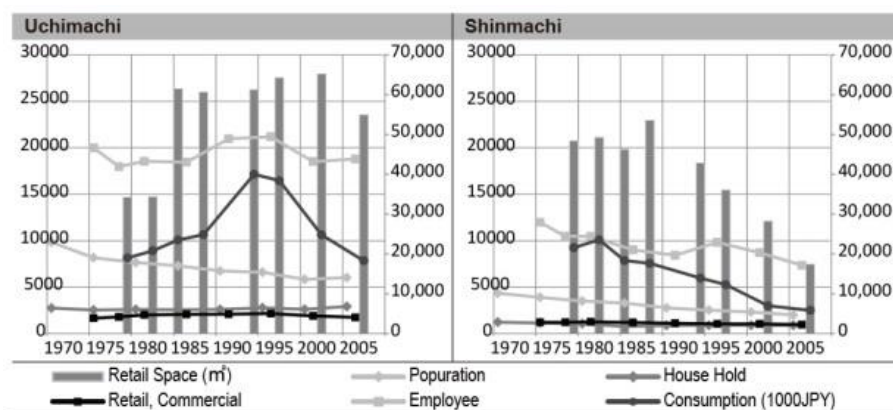

Figure 2. Transformation in Uchimachi District and Shinmachi District.

It is confirmed that parking lot plottage (proportion designated in parking lot) increased from 66,335 square meters (5.5%) to 129,936 square meters (10.8%), more than double within 1,206,000 square meters of the target area. This explains buildings are demolished, or converted into parking lots, hollowing out phenomena in the downtown is remarkable (Figure 3, Figure 4). Comparison with the tendency of increases of large commercial facilities in Uchimachi district, decreases of large commercial facilities in Shinmachi district is sharp, and rather serious. As for the shopping arcade (shopping mall) around half is driven into the closing a shop by the aging of the storekeeper, the issue of inheritor, and, unoccupied situation and ended up being the parking lot, this increase tendency is remarkable in the Shinmachi district. Furthermore, it accelerates a “Shuttered Street” literally.

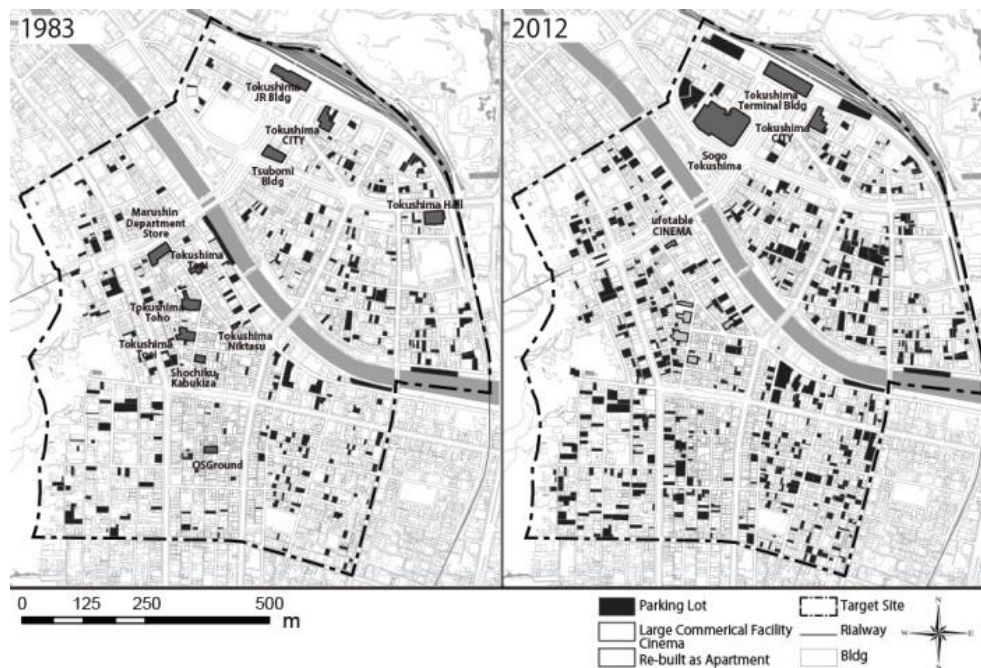

Figure 3. Transformation of parking lots and buildings in the city center (1983 and 2012).

Furthermore, the movie theaters in the downtown got damages severely, due to the ground opening of suburbs type large shopping mall, Fuji-Grand Kitajima (2001) including the cinema complex. As a fact, the movie theaters in the city center closes chronologically; OS Ground (2002), Tokushima Toei (2003), Tokushima Toho (2005), Tokushima Hall (2006) and, with an advance of acceleration in decrease of the number of customers to the Shinmachi district. After 7 years of Zero movie theater in the downtown, a movie theater (ufotable CINEMA) showing mainly on animated cartoons opened in March, 2012 as a dynamo of regeneration

Figure 4. Transformation of Parking Lots Areas (1983 – 2012).

The most of the abandoned sites of large commercial and cinema facilities, which drew large number of customers turned into large-scale high-rise apartments in the Shinmachi district, the aspect of the shopping mall underwent a complete change (Fig. 2, Fig. 3). The opportunity to visit the Shinmachi district became less and less, because the large commercial and cinema facilities which drew customers from the city or even from prefecture level closed down. In fact, people except a neighborhood resident and t commuters to the school and to work rarely visit the Shinmachi district. As a result, the walker route (pedestrian route) with excursion characteristics of Shinmachi Bashi → Higashi Shinmachi Shopping Arcade → Konya-machi & Ryogoku-cho → Ryogoku Bashi from the JR Tokushima Station diminished.

Assessment from Transformation of Transportation Network and Facilities

The construction of the bypass road (National Highway No. 11 & No. 55), the opening of the expressway (Kobe-Awaji-Naruto Expressway) under the opening of Akashi Great Bridge (1998) promoted the express bus services and enabled easy access to Osaka and Kobe for approximately two hours in one way. It was the trigger of the many people of Tokushima travelled out to Kansai Area for shopping (Figure 5). Ironically, it caused the straw effect to draw large number of customers to the outside metropolitan area, and ended up causing the acceleration of the decline of local industry, business, and the emptiness in the downtown area by a transportation network enhancement.

Figure 5. Transformation of the number of users in different transportation system.

Assessment from Transformation of Retail & Commercial Facilities

Figure 6 classified the opening and closing of retails such as shops and stores, and commercial facilities categorized by a radius of 1 kilo around Shinmachi Bashi, 2 kilos and 5 kilos zone. Retail floor areas suddenly increased by Sogo Tokushima (27,000 square meters) to be built into the abandoned elementary school in the Uchimachi district in 1983. The amount of product sale increased gently, but is suddenly depressed in 2000.

On the other hand, the amount of product sale gradually decreased in the Shinmachi district after 1980. As for this, the bankruptcy of the two biggest commercial facilities of the Shinmachi mall created a major negative impact, they are called Marushin department store (7,898 sq. m) in 1995 and the Daiei Tokushima shop (4,097 sq. m) in 2005. Moreover the advance of the suburbs type large shopping centers, called “Suburbanization of Commercial and Shopping Facilities” made a significant impact to the closing down of retails and commercial facilities in the downtown.

Figure 6. Opening and Closing of Retail & Commercial Facilities.

Tokushima City Centers Urban Transformation

Case of Awa Dance Festival

Tokushima is well-known as Awa-Dancing Festival. It is originally developed in the region of Tokushima, and now a big attraction for the tourist in Tokushima. Despite its religious aspect, the parades by the group of dancers and musicians along the streets draw peoples' attentions, and it developed as a tourist attraction. It grew one of the largest dance festivals in Japan, and it attracts over 1.3 million tourists during 4 days in August¹²⁾.

Performance Places and its Transformation

Type of dancing and performance spaces is divided to four periods¹⁴⁾ according to Bando's

research. Lately, two distinctive performance types could be defined, one is regular & organized, and the other is irregular & dis-ordered.

Period 1 (Icho-Mawari: Edo Era - 1955)

The group of dancers is formed based on the community areas such as towns and districts. The areas for the performance are rather limited to the community neighborhood.

Tokushima City is the castle town that the lord Hachisuka constructed from 13 to 15 years by utilizing large/small seven islands scattered in the delta zone, the mouth of the Yoshino River (Figure 7).

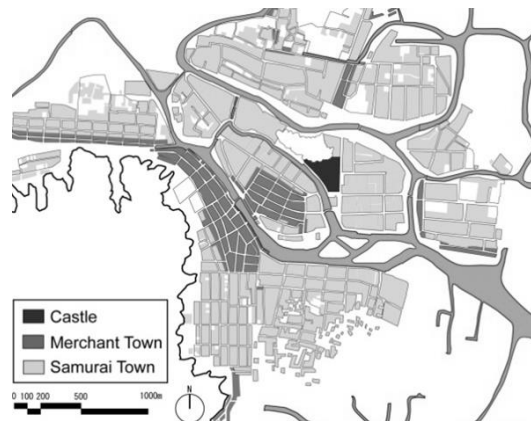

Figure 7. Samurai and Merchant district (16th Century).

Period 2 (Sajiki and Contest: 1929 - 1971)

Sajiki is temporal wooden structured seating facilities where people can watch the performance of dancers. Contest was conducted to access the level of performance. Through the time, the area got larger in scale.

The castle town was divided into the samurai district where the castle located in the center, and the merchant district for commercial and trading along the river. The railway station was built in 1899. The station became an urban center in the downtown, however as a result the center area had been divided into parts (Figure 8).

Narrow roads were changed to the urban roads authorized in city plan of 18m and 12m. After the war, damage-recovery plan was made in 1955, a new axis from the station square to the Bizan Mt. was planned as a symbolic street, and the extra width road of 50m was constructed. A lot of performance spaces were able to be installed along/on the widen road, as well as along the city planning road (Figure 9).

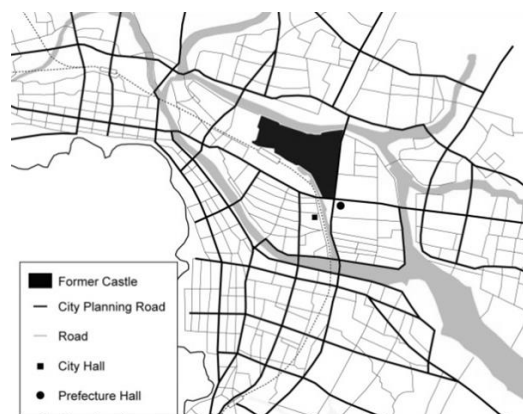

Figure 8. City Planning Map (1937).

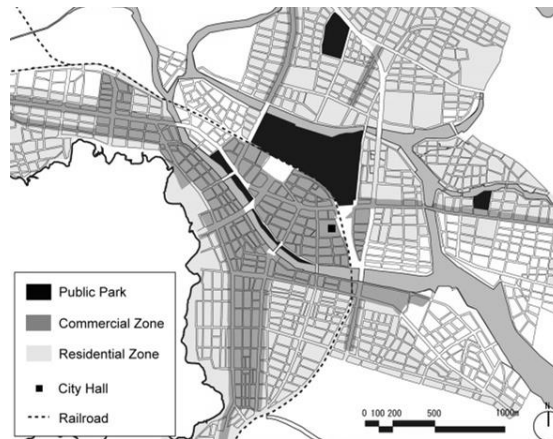

Figure 9. City Planning Map (1957).

Period 3 (Street Theater: 1965-1995)

Street theater is further developed version of Sajiki. Structure was transformed from wood to steel to accommodate more audience. Organizers define the area where people are allowed to dance and play the music. This can be seen in nowadays.

Period 4 (Street Theater and Street Corner: 1992-Current)

Steel made seating is carried on and remained as a designated dancing performance area. On top it, the dancers began dancing around the corners of the streets, open spaces where the organizers did not designate as performance areas. This is a strong character of Tokushima.

During the Festival (Surveyed in 2012)

Figure 10 shows the temporary installation (gallery seat, electric spectaculars, signboard, toilet, and garbage box, etc.) set up for the festival was investigated, which could affect dancers and audiences navigation, as well as overall trace of dance teams' traces (17:00-23:00) to clarify the relationship between those.

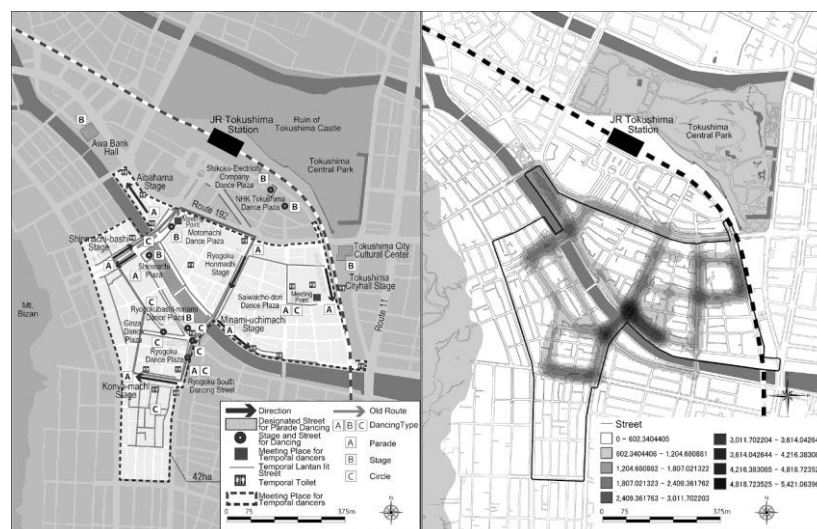

Figure 10. Downtown of Tokushima during Awa Dance Festival (Left: Temporarily Installation, Right: Trace of Dance Team Route).

Catalyst Analysis

Urban transformation originated from the development of Shinmachi Board Walk and a Parasol Shop for the inflow from the Uchimachi district for the purpose of the activation of the Shinmachi district. And analyzes was conducted focusing on community development for town planning almost acting like a chain effect, the connection and networks of human relations are well related to the regeneration of the area afterwards.

Situation before the Shinmachi River Restoration

The hearing interview to the president of Shinmachi River Saving (NPO), also the publication by this NPO, the evidence was told that the river bank was totally reinforced by the Concrete Parapet for disaster prevention, after the extremely strong typhoon hit the area in 1961, the area was suffered from the serious damage.

The decline of the means of transportation by water, taste of the less human being, out of scale, etc. ended up the life of citizen apart from the river, and the river bank was shifted to the parking spaces for the auto mobiles. Then, the river front became the back side of citizen's daily life, another word, demoted from the main stage of the life to the backyard of city, people's place. When the water pollution of the river worsened by an inflow of factory effluent and the home drainage, and the river became the place where the bad smell occurs and no fish could dwell, obviously people will be away from the river even seriously, and caused less human activity, transformed to un-attractive and lonely place. In fact, nobody likes the river at all.

Shift of the Shinmachi River Restoration

The citizen group including the NPO (Non-Profit Organization) called "Saving Shinmachi River," started up to clean a polluted river once again, triggered a local governmental support both in prefecture and municipal to initiate a project to revitalize it for citizen's life and amenity. Figure 11 shows the development and the sectional transition of the right-side river bank (1989-2012), Figure 12 shows the river bank's restoration situation in a chronological order (1971-2012). In the Shinmachi River, it began with water purification project, followed by the development of Shinmachi River Water Front Park on the left-side bank, and beautification of the bank surface covered by the domestic bluish stones on the both sides, and in the end the completion of the Shinmachi River Boardwalk, these chained effect of river development taken place from 1989 to 1996 as an oasis for citizens.

Figure 11. Development and sectional transition of River Bank.

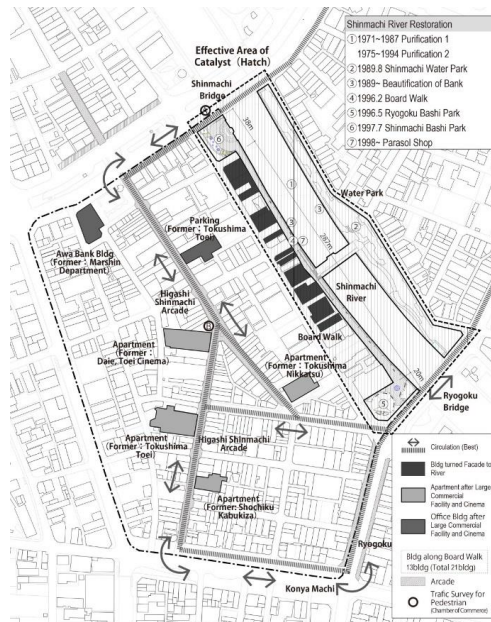

Figure 12. River Bank' s Restoration in a Chronological Order (1971-2012).

Shinmachi Board Walk

The Higashi-senba Shopping Arcade Promotion Association of the Shinmachi district promoted and executed "Higashi-senba Boardwalk Restoration Project" and successfully, the wooden decked promoted was constructed along the right-side bank of the Shinmachi River. According to the local architect, Nakagawa, "It was such a pity that most of the buildings along the river faced to the street, in another words, back side of buildings face the river front. Then, his design intention was creating a river front park with a total extension 287m consists with river bank board walk between Shinmachi-Bashi and Ryogoku-Bashi, Higashi-Zume Park of Shinmachi-Bashi, and Nishi-Zume Park of Ryogoku-Bashi all together as Urban Park.

Thanks to the Shinmachi River Purification Project, attention to the river, and the water front for the citizens had begun to revive to a citizen, and triggered the campaign of community development and town planning with the river initiated by the Higashi-senba Shopping Arcade Promotion Association. This evidence proved that purification the river water and the beautification of the river bank development brought citizens attentions and Patriotism for the further effect of utilization of river front, as well as bringing citizen's life back or co-exist with the river. Figure 13 shows the significant change before and after the completion of the board Walk. It generates accessibility to the river, and permeability to the river. Built environment along the river was dramatically changed.

Figure 13. Before (1990) and after (2012) of Board Walk Development.

Parasol shop

Parasol shop (Fig. 14) is the temporal shopping mall to sell agriculture products and processed foods along the Board Walk.

Fig. 14 Parasol shop.

After the completion of Board Walk in 1996, parasol shops started its operation, the nature of Newness, trendy movement; it brings vitality along the water front temporally. However, the turnout did not continue for a long time. The sales decreased, and, due to un-strategic opening of the shops by professionals and immature retailers, often did not match with customers' demands and needs, ended up shrining and downsizing the market.

Hyotan-jima Cruising

When the Youth group of Tokushima Society of Architects & Building Engineers, manifested "Renaissance of Hyotan Island", the idea and the nick-name of Hyotan Island became familiar with the citizens of Tokushima in 1984. The sandbank surrounded by Shinmachi River, Suketo River, and Fukushima River branches of the Yoshino-gawa River, has been forming a downtown, a center of commerce for the citizen. Only one man began the campaign of cleaning the river, and bringing fish home. Soon after, in 1990, ten individuals gathered around him, and made a slogan of "The river was contaminated by the citizens, therefore, us, citizens are responsible to clean the river, and bring it to original cleanness". It ended up a launch of NPO for "Saving Shinmachi River".

According to the hearing investigation, it began to navigate a cruise ship, one lap of 6 km regularly at the same time to begin the cleaning of the river with the boat twice a month. In late years the number of the visitors gradually increases and reaches 5,000 monthly passengers and grows up as tourist attractions steadily. In addition, the events utilizing a river are organized all through the year, as well as cleaning of the river. Moreover, the role of letting people recognize a boardwalk as an event place, almost "Landmark of the City" by planning various events simultaneously such as Tokushima LED Art Festival, Machi Asobi, an event in connection with Hana-Haru Festival.

Analysis of Catalyst Effect

Change in the Flow of the Person

The result of quantity survey of pedestrian traffic flows in the Tokushima city's downtown along the central shopping street are shown (Figure 15). The quantity of pedestrians increases in 1,999 in comparison with 1996 on the weekends and the holidays around Shinmachi River Area. It is understandable due to the effect by the completion of the Board Walk and the success of the parasol shop.

Figure 15. Pedestrian traffic flows in the Tokushima city's downtown.

Upon the completion of the Board Walk, the previous parking lots under prefectural management became the city park, and eating and drinking, the sale of the above related articles were enabled. Profit utilization spreads, but I gradually show a tendency to decrease, and it is considered that the effect was temporary, but the increase is again observed after 2009. It should deserve high attention.

Chain Effect to the Neighboring Facilities

Transformation was observed in neighboring facilities like a chain effect by the construction of the Shinmachi Board Walk after the completion of Water Front Park. The buildings which turned the face to the river side increased. Original expectations was realized, the ratio of more than 50% of the building, in fact 13 buildings out of 21 buildings along river front turned the façade and face to the river. Although there are still issues remains such as less harmony of the buildings as a whole, each buildings' design quality and integration remained still very low, etc. The building was refurbished to arrange permeability to the Higashi-Shinmachi shopping arcade from the river (Figure 16). These are caused by two main reasons; Shinmachi Boardwalk was considering as a road which allows "building permit" by code to the adjacent site, and a parasol shop brought the citizens attention. As a catalyst effect, expected chain effect was observed around the built environment. Parasol shop acting as an incubator, or start-up shops to initiate permanent stores around the downtown as a chain effect, as a result, 26 new stores opened around immediate context, 14 stores opens in the neighboring shopping malls.

Figure 16. Buildings along Board Walk.

Conclusion

In this research, the following aspects are identified and clarified to understand the cause and effect of catalyst each other: 1) before and After of physical phenomena applying catalyst, such as the number of building upgrade, amount of pedestrian traffic flow, 2) through the hearing survey to the event organizers and government officials, to understand their intention and motivation of events, and to find out the relationship developed between each catalyst effect. As a result, the following things became clear: 1) primarily, the interest of citizen began toward the river by purification work of the Shinmachi River, which is defined as the

first stage of catalyst; 2) secondary, the campaign and promotion of creating Shinmachi Boardwalk and a parasol shop emerged, because a Shinmachi River Park was restored. These two are private enterprise-based development called the Shopping Street Promotion Society and are not by the public sector like government. This is defined as a chain effect of regeneration of Shinmachi River, and categorized as a second stage of catalyst; 3) when Shinmachi Boardwalk and a parasol shop were completed and running its business, the increase of the building which face, frontage turned toward the river side are confirmed. This is the third stage of catalyst, and the influence on physical phenomenon, to the built environment are confirmed even beyond the target area.

These series of city regeneration was not originated from the governmental vision, because, by understanding a conventional development method, it assumes the change is limited in the targeted area. Envisioning chain effect to the surrounding context and neighbor are beyond the consciousness. Moreover, within the limited budget for regeneration, government tends to narrow down the scope of development, which is a strong character. As a good example of Shinmachi Boardwalk, it promotes the next development activity by a chain effect, and city regeneration is accelerated and realized by the synergy of all the involvement.

To conclude, it is desirable to find more successful and similar examples, and analyzing those samples to identify common aspect, generality, and tendency, to establish the theory of urban catalyst, as approaches to experience based urbanism for matured and shrinking society like Japan.

Diaspora typo-morphology analysis: a study of post-colonial city in critical approaches

Po-ju Huang, Chaolee Kuo

Department or Centre, Institution. E-mail: pajuhuang@gmail.com.

Abstract. *Diaspora is a spatial representation of colonialism, that is also prime phenomenon of urban is constantly duplicating and reproducing urban form. Colonial city's planning often by the advanced standards of Western countries equitable distribution of the overall planning in order to erase the gap between the local and construct the hypothesis of a homogeneous city by ignoring the people's "sense of place". In fact, during the process of spatial practice, standardize modification would be impossible to complete, and only highlight the complexity that populations and societies possess in colonial cities. In recent years, development in Taipei is dictated by the economics of space, creating competition between builders and politicians. Many new plans for the redevelopment of industrial sites show how global capitalism has resulted in a homogeneity of architectural types. Such implementation often contradicts local traditions, resulting in a discrete landscape, a grafting of modern and traditional urban forms. It's not only show the "practice of social behavior" and "spatial practice" to simultaneously, but also combine with each other or resistance to each other. In order to analyze the diaspora phenomenon, we attempt to explore the historical changes that took place along the city's borders and explore Taipei through morphological analysis and narrative scenes in order to understand the Diasporas typo-morphology. The study combines urban form weaving together a complex web of relationships, analysis and dialectic relationship between buildings, open space and social practices in order to critical the local traditions meaning and contradictions of modern city, that as a reference for future development of urban space.*

Key Words: *de-construction , post-colonialism ,typo-morphology ,diaspora, hybridity*

Introduction

Diaspora is a spatial representation of colonialism, a migration of people or communities, voluntarily or by force, temporarily or permanently. That is also prime phenomenon of urban is constantly duplicating and reproducing urban form. During this dynamic process, a variable is constructed through new examples that can be highlighted spatially. More like approaching modernity "diaspora space".

In the context of Taiwan's development, there were three major migrations: the early settlements of the Han Chinese, the Japanese colonial immigrants, and the large-scale postwar retreat of the Nationalist Chinese. They symbolized the end of traditional society and the coming of modern world. Railways weakened symbolic society and gave rise to spatial rationality.

Taipei's urban environment in the twentieth century has had to confront the contradictions of imperialism and modernism. As such, the economic-oriented urban culture arose from a grafting of colonial modernity to the growing influence of the post-war United States, which extended to the development of today's neo-liberalism as manifested in "product building" and the "instant city". Therefore, the structural collapse of the traditional urban landscape and architectural type threatened to disappear, along with a "sense of place" in the historical context. In the face of consumerism and globalization, we have been unable to grasp the urban artifact.

This article discusses the transformation of Taipei's urban form from 1880 to 1945, and how the natural result of its expansion is an artificial outgrowth of the modern nation state's authority mechanism. Examples include the walls of the late Qing Dynasty- the railways of the Japanese occupation, avenues, Nationalist government buildings, fairs, illegal buildings,

shopping malls, etc. These different forms created space and shaped the landscape over a few decades, constantly creating new patterns that appear and are later replaced. This process of change is the object of study in urban space, and reflects the unique growth trajectory of Taipei city.

Figure 1. In the context of Taiwan's development, there were three major migrations: the early settlements of the Han Chinese, the Japanese colonial immigrants, and the large-scale postwar retreat of the Nationalist Chinese.

Figure 2. In recent years, development in Taipei is dictated by the economics of space, creating competition between builders and politicians. Many new plans for the redevelopment of industrial sites show how global capitalism has resulted in a homogeneity of architectural types.

In order to analyze the diaspora phenomenon, we attempt to explore the historical changes that took place along the city's borders and explore Taipei through morphological analysis and narrative scenes in order to understand the Diasporas typo-morphology.

Such implementation often contradicts local traditions, resulting in a discrete landscape, a grafting of modern and traditional urban forms. It's not only show the "practice of social behavior" and "spatial practice" to simultaneously, but also combine with each other or resistance to each other. The study combines urban form weaving together a complex web of relationships, analysis and dialectic relationship between buildings, open space and social practices in order to critical the local traditions meaning and contradictions of modern city, that as a reference for future development of urban space.

Weakening of "local community": edge and enclosed lay the foundation for the unique characteristics of diaspora

In the Man-Ga and Twa-Tu-Tia districts between 1882 and 1884, the late Qing government's construction the city walls of Taipei Fu created an administrative settlement with other two ethnic groups not strongly associated with an enclosed regional urban landscape. At the same time, belief that the introduction of the modern western rail system risk of would open late Qing China to the Western colonial powers led to the first railway (1893) not being built in the cities of the Chinese mainland, but on the island frontier, specifically in Taipei.

Two projects of walls and railway were designated for the late Qing Dynasty Taipei city, but the presence of both common to feudal cities created a challenge. Planners were presented with a conflict of modern and traditional ideas, with the city wall adopting the periphery to imperial order, whereas the modern railway improving the development to modern world. Though the two ideals are in conflict, they did develop a symbiotic relationship in the beginning.

At the second half of the 19th century, the Qing government shifted its policies from "passive governing" to "active governing," however, it's governance of epistemic rationality (Foucault; 1970) different from the conservative views of local society restricted Taipei to the three segregated settlements layout, rather than a single unified modern urban landscape. Nevertheless the relationship between government and society was not one of tense isolation and confrontation, but rather isolation with cooperation, contributing to the unique nature of diaspora, one that accepts and tolerates differences.

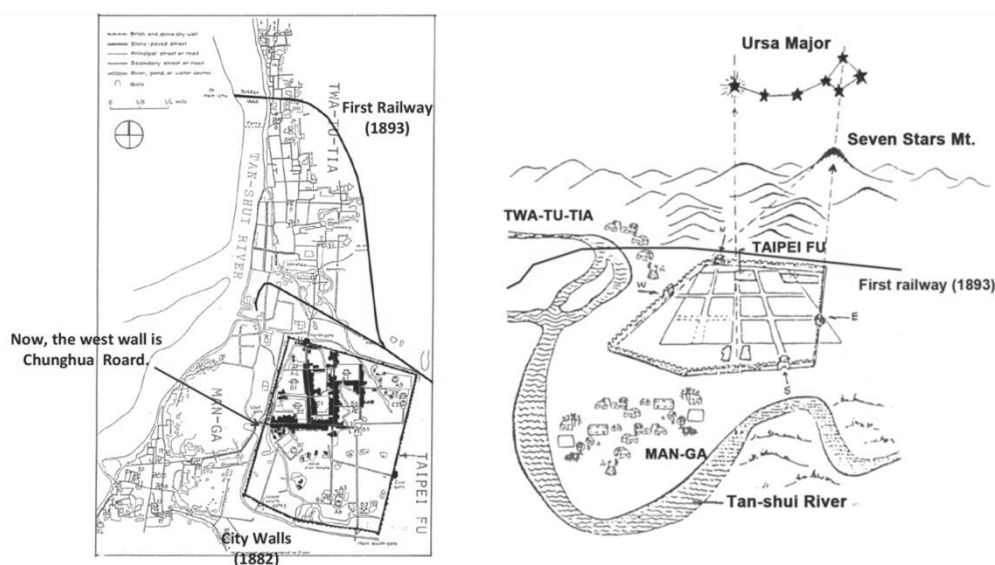

Figure 3. Planners were presented with a conflict of modern and traditional ideas, with the city wall adopting the periphery to imperial order, whereas the modern railway improving the development to modern world. Though the two ideals are in conflict, they did develop a symbiotic relationship in the beginning.

Rising of "new community": urban planning highlights the spatial differences

Edward Said in the book *Orientalism* (1978) pointed out that the reality of colonial rule is not how it is manifested in the West, but a representation. In addition to being a colonial power and more than a reflection of the West, Japan has learned the true value of description, calculation, and analysis, becoming an important engineer of change. For Japan, urban form provided the tool that empowered the imperial government to achieve its goals.

After the 1895 Sino-Japanese War, Taiwan became the first colony of the Empire of Japan and as such was a symbol of the empire's vision for modern urban development and infrastructure improvement. The stretches of railway and supporting infrastructure meant significant changes for Taipei and Taiwan. The importance of the island's traditional harbor cities in Taiwan's economic development was superseded by rise of the industrial cities that sprang up along the new mountain line. With the transformation of the island-wide regional production space, many cities within this new urban landscape faced unprecedented change. This resulted in a "space compression" era in which the sense of distance disappeared with the growth of personal mobility and transit speed (Lardner, 1968).

Figure 4. The stretches of railway and supporting infrastructure meant significant changes for Taipei and Taiwan.

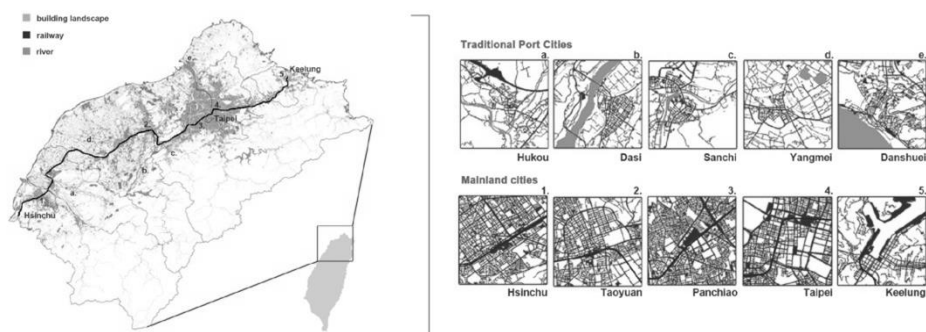

Figure 5. The importance of the island's traditional harbor cities in Taiwan's economic development was superseded by rise of the industrial cities that sprang up along the new mountain line. With the transformation of the island-wide regional production space, many cities within this new urban landscape faced unprecedented change.

A major flood in northern Taiwan in 1912, the colonial government took the opportunity to implement urban renewal in connection with three settlements of Taipei, that processing of planning attitude is guidance rather than spontaneous. For viceroy authority to have an impact, the concept of "place" must be eliminated. There can be no spatial differences; the original differentiating characteristics have to be forgotten. After the integration of three settlements, the residents no longer enjoyed a sense of togetherness (place), and began to experience feelings of metropolis, separation and anonymity.

In the Japanese period the empty space among three settlements was developed as Seimoncho new district, which would include Japanese shops, residential gathering areas, and Seimon Market on the east side of boulevard (i.e. Chunghua Road), which serviced

mainly Japanese residents. Late at night, shops and street vendors remained open and the area buzzed with the sights and flavors of a Japanese night market.

The railway and urban renewal are new urban morphology in the Taiwan. And railway station is a new typology introduced by railways. It is the most conspicuous spatial transformation relating to the fading of localized society and the transition towards spatial universality. Anthony Giddens stated that “spatial planning has only become necessary after the emergence of modern nations; it means to take away the ‘place’ meaning of the land so it becomes a space with nothing to hold it back, a tool of governmental authority.” (Giddens, 1991:16)

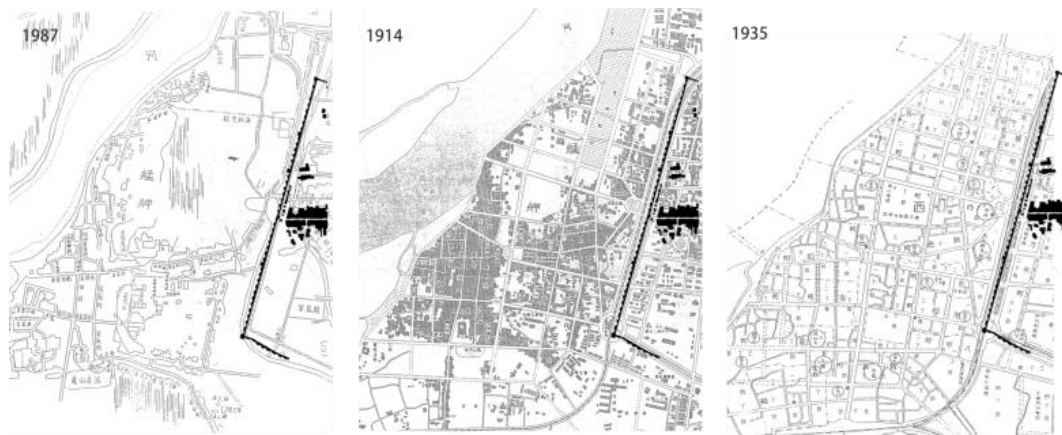

Figure 6. After a major flood in northern Taiwan in 1912, the colonial government took the opportunity to implement urban renewal in connection with three settlements of Taipei, that processing of space engineering attitude is guidance not rather than spontaneous.

Figure 7. The railway and urban renewal are new urban morphology in the Taiwan. And railway station is a new typology introduced by railways.

The rise of Taipei: precipitated of spatial and social creative a new city layout

The periphery of three settlements began to create a new morphology. For example, the creation of law enforcement institutions (colonial administration, prison, police stations) established constitutional politics, while the emergence of banking (e.g. Imperial Bank of Taiwan) introduced economics into the equation. Next, consider the establishment of numerous elementary and middle schools (e.g. Lao Song Elementary School) aimed at ideological indoctrination under the colonial power structure. And other building types

developed, such as industries (distilleries, tobacco factories, sugar refineries) and healthcare facilities (e.g. Imperial Taiwan University Hospital and Public Health Bureau).

The colonial government expanded the role of spatial power with its new system of knowledge and ruling institutions. Nevertheless, to combine and distinguish the self from that which is alien or the other, reconstruction of spatial order was attempted from “periphery”. In practice, however, deconstruction had begun. Of course, urban morphology made a difference under the new order. The Japanese attempted to introduce the imagery of Western colonial imperialism to Taiwan’s urban spatial system, mixing elements of two (or three) very different lands and people. Such imagery had to be combined under one state system, while also attempting to eliminate social factors through spatial segregation. This contradictory relationship resulted in the complexity of Taipei’s urban space.

With the conclusion of World War II and the defeat of Japan, 50 years of colonial rule in Taiwan came to an end. However, the retreat of the Nationalist government in 1950 brought a flood of people to the Chunghua Road area. This prompted the construction of temporary refugee housing to accommodate fleeing soldiers and civilians from the mainland. Suddenly, the beautiful boulevard transformed into a refugee camp, a home to mixed ethnic groups of different lifestyles and cultures. In order to improve the quality of life for these people, President Chiang Kai-shek ordered the renovation in 1961 of eight three-level shope-houses to create a new typology — China Mall.

This appeared to reflect the simple form of the modernist-style buildings. The complexities of the modern urban space meant that buildings were crowded with various forms of signs and advertising. A pedestrian overpass connected the previously Japanese side of Chunghua Road with the newly developed zone and within a very short time Taipei became important conduit for modern life. China Mall integrated the concept of Chinese culture with all variety of local traditions, rather than focusing specifically on Fujian, Guangdong and Japanese colonial culture. It became a miniature hybrid city center of post-war Taipei, and the best representation of the city as a whole.

Figure 8. President Chiang Kai-shek ordered the renovation in 1961 of eight three-level shope-houses to create a new typology - China Mall.

In nature a hybrid is not a single species or breed but a combination. Similarly, hybrid culture is not a single culture. When one’s attention is not focused on pure culture, one is less prone to be influenced by so-called cultural purists. From another perspective, tolerance opens the way to hybrids. The hybrid is a deep cultural mix, not just the juxtaposition of different cultures, and it focuses on the parallel coexistence of different cultures in an area along with a different culture’s right to exist and develop its identity.

The impact of capitalism: lack of counteractive to the development of space in globalization

After the 1980s, with Taipei's commercial center shifting eastward and the emergence of globalization, development focused on modernization. However, Taipei is an extremely dense city in which land is difficult to obtain, hampering development. With the moving of the city's rail lines underground and the demolition of colonial industrial sites, land developers and politicians competed for access to newly available open space. The China Mall was demolished in 1992 after standing for a short span of just 31 years (1961-1992).

Along the railroad many industrial redevelopment projects illustrate the homogeneity of architectural forms within global capitalism. Building types such as department stores, shopping malls, and skyscrapers conflict with the traditional local urban landscape and sometimes result in a grafting together of disparate elements with chaotic results.

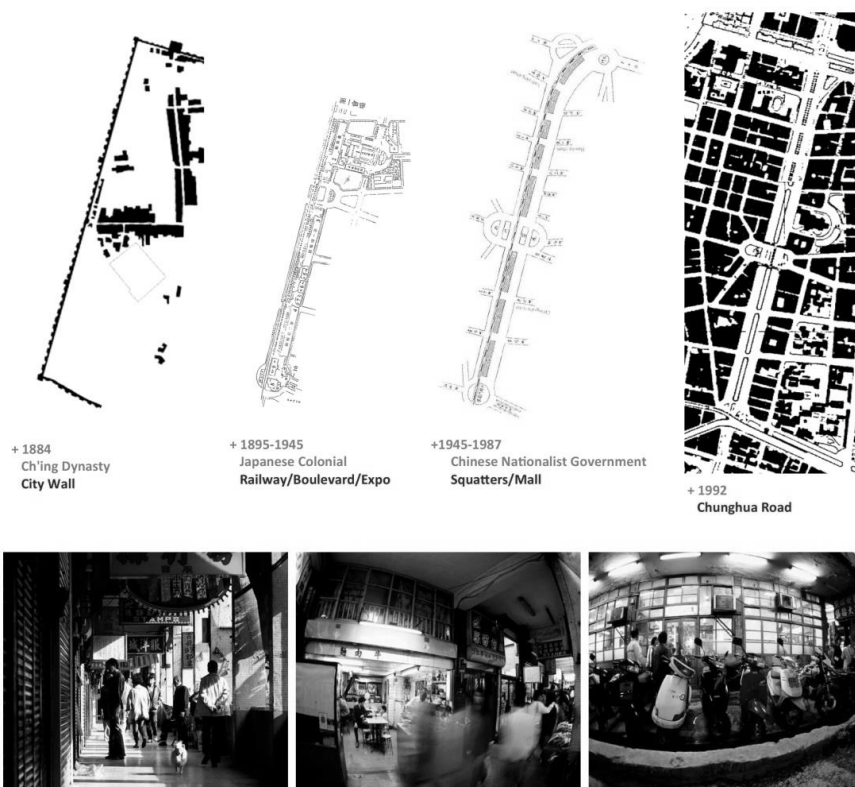

Figure 9. The hybrid is a deep cultural mix, not just the juxtaposition of different cultures, and it focuses on the parallel coexistence of different cultures in an area along with a different culture's right to exist and develop its identity.

Figure 10. After the 1980s, with Taipei's commercial center shifting eastward and the emergence of globalization, development focused on modernization.

Local city planning by the advanced standards of American and European countries pursues equitable distribution of the overall planning in order to erase the gap between the local and construct the hypothesis of a homogeneous city by no longer ignoring the people's "sense of place." By creating uniform benchmarks for spatial distribution in urban construction rather than focusing on integration with local character, excessive emphasis has been placed on modernity. This has resulted in a confounding disconnection between residents, society and the urban landscape in the colonial city.

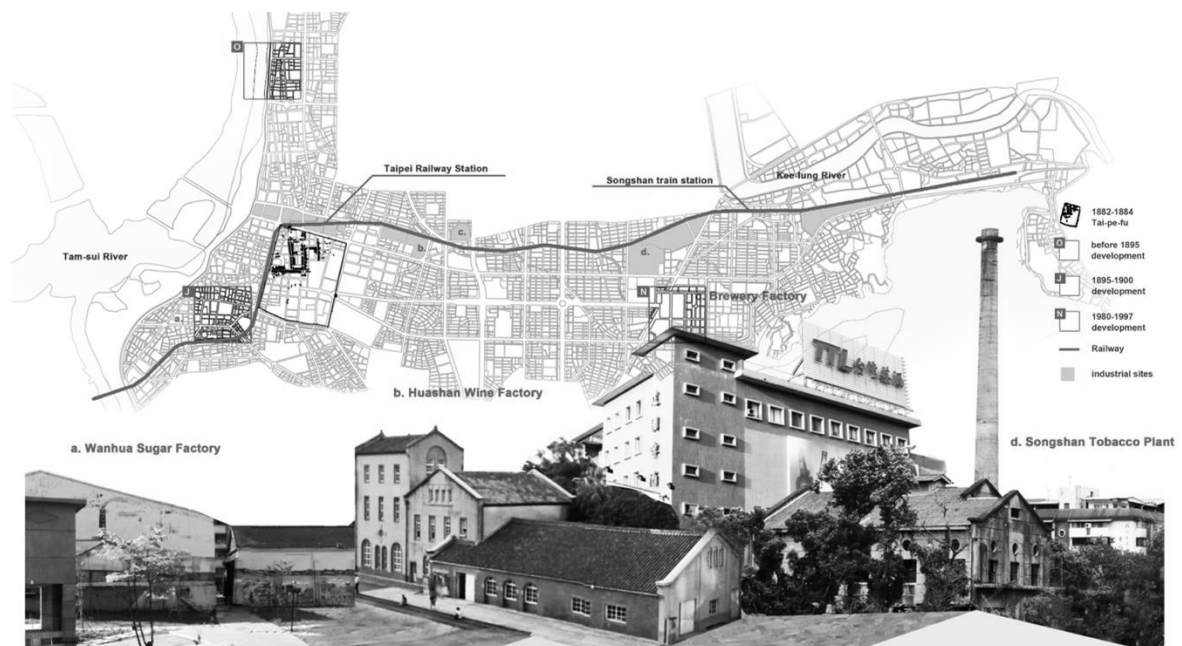

Figure 11. Along the railroad many industrial redevelopment projects illustrate the homogeneity of architectural forms within global capitalism.

Conclusion: each city must develop its own space on the counteractive of typomorphology by critical approaches

During the process of spatial practice, standardize modification would be impossible to complete, and only highlight the complexity that populations and societies possess in colonial cities. Looking at large-scale urban adaptations from a spatial point of view, one clearly sees new urban blocks generally mixed in with old alleys. Space is still diverse mix, but the standard was implicit in the era of the moment, which is a spatial structure is also a process of deconstruction.

In this hybrid landscape, include those who homogeneous space generated by centralization, there are a number of heterogeneous edge of space in the city. They may accept the change, perhaps to resist change. These are panting for a chance to face major rule era, but in terms of the city is very important. Rich and interesting city, because the production of different social identity through every hybrids space, and even the creation of a different culture. Therefore, the production of space can also be the production of new social relations, space is social.

How to see the counteractive of hybrids space? Planning scholars Nihal Perera said 'clarify the relationship between the resistance or institutional behavior and rules of the system, he pointed out rebel action is not exist independently, but often entangled together with the formal system, making the space to do the cutting becomes almost impossible. He stressed: "These vulnerable people in society created by the edge of space and can not

completely replace the hegemonic narrative space, but the presence of these narratives can be localized and contextualized.'

As stated by Paul Ricoeur (2007): "I shall call for the time being the creative nucleus of great civilizations and great cultures, that nucleus on the basis of which we interpret life, what I shall call in advance the ethical and mythical nucleus of mankind." This space can be defined as a "living space" where the inhabitants or users have some degree control over it. Therefore, emphasis should be placed on the fact that though planners follow a narrow ideal of scientific and architectural standards, residents have the power to reshape the space and give it new meaning. However, space is liable to be eroticized and restored to ambiguity.

Abstract. *This research comes from the idea that the tools of urban morphology can be applied on 'informal' contemporary city. Informal fabrics are basically spontaneous fabrics, but 'spontaneous' are a large part of the pre-modern urban fabrics on which urban morphology developed as a discipline, let us recall the studies of MRG Conzen on Alnwick and those of S. Muratori on medieval Venice. It is possible then to find some interesting morphological analogies between the urban processes of pre-modern historical cities with those of the major slums in many contemporary metropolises. Starting from this assumption it was taken the case study of the Villa 31 in Buenos Aires. This fabric is of great interest for the purposes of our work. It is located in a strategic position with respect to the historical and economic centre of the Argentine capital, between the harbour, the railway station and the compact fabrics of the consolidated city. It is crossed by a main motorway overpass, the Autopista Presidente Arturo Illia. It has already a first social and building stratification that makes it a very useful example to extend to other similar cases. The application of the urban morphological tools to contemporary slums should, in our opinion, make it possible to critically understand the transformation processes of these kind of neighbourhoods (often considered chaotic, illogical and so 'unreadable'), either from the urban point of view and from the social-economic aspects, in order to consciously design the regeneration of its fabrics. This is the direction of our research on Villa 31 and the approach taken on other similar situations on which we are still working.*

Key Words: informal city, urban morphology, social and urban transformation, urban design.

Introduction

This research comes from the idea that the tools of urban morphology can be applied on 'informal' contemporary city. Informal fabrics are basically spontaneous fabrics, but 'spontaneous' are a large part of the pre-modern urban fabrics on which urban morphology developed as a discipline, let us recall the studies of MRG Conzen on Alnwick and those of S. Muratori on medieval Venice. It is possible then to find some interesting morphological analogies between the urban processes of pre-modern historical cities with those of the major slums in many contemporary metropolises. Starting from this assumption it was taken the case study of the Villa 31 in Buenos Aires. This fabric is of great interest for the purposes of our work. It is located in a strategic position with respect to the historical and economic centre of the Argentine capital, between the harbour, the railway station and the compact fabrics of the consolidated city. It is crossed by a main motorway overpass, the *Autopista Presidente Arturo Illia*. It has already a first social and building stratification that makes it a very useful example to extend to other similar cases. The application of the urban morphological tools to contemporary slums should, in our opinion, make it possible to critically understand the transformation processes of these kind of neighbourhoods (often

considered chaotic, illogical and so 'unreadable'), either from the urban point of view and from the social-economic aspects, in order to consciously design the regeneration of its fabrics. This is the direction of our research on Villa 31 and the approach taken on other similar situations on which we are still working.

The typological process

In the informal city, the rules of urban morphology are often based exclusively on economic issues and behaviors related to lifestyle culture. The occupation of the lots and the absence of laws makes the urban expression a text devoid of contamination superimposed in which the researcher is able to analyze the social and cultural needs that cause the urban changes. However the study of these phenomena is often not a simple exercise: governments tend to ignore the problem and, in the official documents, these areas simply do not exist and it is impossible to find any evidence of urban transformation. So the only analysis workable is the direct one and the urban transformations can be deduced only through the stories of the inhabitants, limiting the scientific nature of the study. In this respect it was considered very useful to analyze the dynamics of formation and growth in the 'formal' context of the urban fabric. In this case, it is possible to trace the reasons for the development and transformation of contexts both by direct analysis of the urban organism, either by the use of documents able to demonstrate the changes in the analyzed fabric. The dynamics of development of the 'formal' city, however, are based on a series of data that depend on the legislation and the need to control the transformations in addition to the economic and cultural problems. So in this case, the analytical tool compared to the contexts 'informal' contains a number of variables that require further interpretation in order to free it from the data are not strictly cultural. This operation is made possible by considering the feature of the building organism generator of the urban fabric. In fact these features contain within them the logical development of the analyzed context and allow evaluating the transformations irrespective of any external variables that come into play from time to time. In the analyzed case, the basis of the urban structure of Buenos Aires consists of the derivations of the development of the *Casa Colonial de Patios*. This courtyard organism is based on a predominantly longitudinal dimension along which develops a series of *patios*, which distribute around the various rooms of the house. The short side is the one that is directly related with the public way and in which is located the entrance on the longitudinal axis of the building. This structure, whose size (20 for 100 varas: 1 varas = 86.6 cm) is practically constant, becomes the generating element of the whole urban fabric: the urban block is formed by aggregation of basic architectural organisms that give rise to the *cuadrícula* mesh, typical of the colonial Latin American cities. The transformation process of this type is developed from the demographic growth of the early nineteenth century. The typological transformations, aimed to respond to the increase in housing demand, define units with an area ever smaller, without big changes to the buildings structure and the urban fabric to allow accommodating a greater number of inhabitants. The first important transformation of the type is developed in the second half of the nineteenth century, with a body that measure 10 *varas* and which is called *Casa de Medio Patio* o *Casa Chorizo* (1870-1915). Its plan is the result of a virtual division along the longitudinal axis of the Casa de Patios and its dimensions arrive to a limit which represents the minimum acceptable for the health and livability: 4m to the covered part of the unit and 4 meters for the *patio* and the area of distribution. In most cases the *Casa de Medio Patio* occupies the whole lot and it going to be a type formed by a sequence of patios, which distribute two or three rooms, up to a number of five consecutive, depending on the size of the lot. This type will remain stable for more than 40 years and become the basis of a large variety of multi-family types. The great housing demand within the city, further compresses the housing units and the new small lots are transformed to accommodate a greater number of inhabitants. This operation is defined by F.E. Diez densification for 'reduction-multiplication' and will become the basis for the establishment of multi-family homes. This

process will lead to the formation of *Viviendas en Hileras* (1890-1940), consists of a sequence of small houses along the longitudinal dimension of the lot. In this case, each *patio* corresponds to a housing unit that conceptually contains in itself the compositional features of a *Casa de Medio Patio*: an access from the path that comes to a courtyard that distributes the various rooms of the house; the served area has a transverse dimension of 4 meters as well as the height, instead the serving area has the first floor of 2 metres in order to obtain another service environment of the same height upstairs which is accessed through a metal stair that starts from the patio. The access to each dwelling is made by a passage on one side and is separated from the *patio* of each unit through a low wall which allows a greater lighting for the small size of the open-air space that lost surface because of the connection path. Parallel to the densification for 'reduction-multiplication' begins the process of vertical development, the process by which the one-story buildings are starting to gain the upper floors. This growth begins with the overlap of the ground floor plan on the first floor while maintaining virtually unchanged distribution. The superposition of several floors leads to the establishment of multi-family organisms as the *Casa Chorizo de Altos* (1880-1925) and then *Casa Chorizo Superpuestas* (1885-1940). During the same period it developed a type defined as *Conventillo Chorizo* that, with the same structure, is a type in which each family occupies a single room, sharing the serving areas. The morphological difference with its mono-family referent is given by the presence of stairs located in each patio which distribute the upper floors that work thanks to a gallery configuration. The *Casa Chorizo Superpuesta* contains the main features of both types: the repetition of the ground floor distribution to the various levels and the presence of stairs in each patio. In this type are accommodated a family in each floor and for each patio and this morphology causes problems of introspection on the ground floor and the upper floors only keeps a visual relationship with the courtyard. From this moment on, the courtyard loses its meaning of center of the house to becomes a space with a just distribution role.

A parallel process concerns the development of *Vivenda en Hileras*. During the first forty years of the twentieth century this architectural organism use an horizontal extension of two lots (*Vivienda en Hileras doble*): the ground floor is mirrored in the next lot to generate a building structure that defines a number of housing units 'in line' with access from the path generated by the recast of the two already existing entries. The combination of the two-mirrored plans allows the formation of a secondary path perpendicular to the public street, which replaces the narrow passage of the *Vivienda en Hileras* and configure a semi-public path. The new path has greater exposure to the sun, as well as patios that in this new configuration, not confine more with the built but with the next *patio*, separated by a low wall. Soon you will begin to open windows facing the new path which links the units and this fact will lead to change the position of the housing units in order to respect the value of new passage which is comparable to a pedestrian public path. The largest change, with respect to the new structure, refers to the location of the *patio* that regains its typical placement on the bottom of units. This defines the type called *Pasaje* whose structure determines units with a distribution more suited to the needs of contemporary society and consists in the rapprochement of the kitchen to the dining room and bathroom to the bedrooms. Further developments are related to the progressive loss of significance of the open-air space that on one side will generate compact architectural organisms, able to use on several levels a significant area of the lot and on the other will develop multi-story buildings (Diez, 1996). This process refers to developments in the 'formal' city of Buenos Aires and defines a structure whose expression derives from dynamics influenced by economic, social, regulatory and formal problems. Therefore, before setting up a comparison between developments of the 'formal' and the 'informal' environments in the analyzed area, it is very important to underline a very important aspect: beyond the procurement of construction materials more or less appropriate, the most important differences between the results of the processes are related to economic issues linked to conditions of occupation of the lot, strongly influenced by the need to optimize the space, even at the expense of a clear division of property, a distinction between public and private or the health housing and the fabric. The starting

hypothesis was born from the analysis of the two distinct urban expressions and identifies the type of the *Casa de Medio Patio*, such as the common denominator of the two fabric; this architectural organism, which is strongly linked to the ways of life of local culture and identity, is systematically used within informal contexts to create mono-typological fabrics or nearly so. The developments of this type, in the two distinct environments, contain some differences but the logic of the growth results, in both cases, are linked with the basic features of the organism.

Starting from the beginning, the first phase of development of the architectural organism and its urban fabric, is realized in the subdivision of the area with the formation of lot of about 200 square meters for each family. Lots occupied measure about 10 x 20 m, size corresponding to the minimum area of a *Casa de Medio Patio*. The main problem is the safety of the propriety and the demonstration of the possession of his lot. A property title cannot be obtained in any legal form or in a short time and the previous show that, once installed on a plot of not important commercial value, rarely there are possibilities of displacement, therefore the safest form of defending the property is to build a strong structure with good foundation. For this reason, the occupants are forced to build on their lots as quickly as possible. The first building is the fence which defines the area of the property. At the same time it forms the first housing unit built with precarious materials because the urgency of defining the occupation. As the *Casa de Medio Patio*, even the makeshift shelters, that form the first expression of informal fabric of the Villa 31, refer to the features of a courtyard organism. The closed fence is the main structure and the covered living space is located on the perimeter, so as to create a distribution open-air space that links each room. Compared to the courtyard type, the main difference you notice analyzing the urban organism of the Villa 31 corresponds to the tendency to open the enclosure with direct openings on the public path. In the urban fabric analyzed, the commerce space is closely related to the house, often to solved safety problems. In this sense *los kioscos* (shops) are part of the homes and have direct access to them. In these cases, the sale space is external and the contacts between customer and seller are held on the threshold of an opening which, in most cases, corresponds to a window or even a door. Therefore the openings on the street are often made in anticipation of a commercial use, because the exchange of goods is one of the main means of subsistence in these contexts. Another very important aspect to take into consideration for the analysis is the concept of courtyard and his use.

We have seen how the Latin-American process, is not only a very short process, from a duration point of view, but also immediately defines a multi-family organism that, if at first tries to keep protected the privacy of the courtyards, then surrenders to the demographics pressure of the surrounding urban fabric, by sacrificing the private use of the open-air space. Actually this part of the house does not lose importance, because becomes the distributor space of more housing units that form a new community that replaces the concept of family, both from a social point of view and from the point of view of architectural and urban organism. In effect, it can be said that until that time the courtyard type had been the matrix of the urban fabrics of the American Spanish colonies but once scaled the demographic problem, the basic type specialized by acquiring a feature that caused the reorganization of both the society and the basic structure of the urban organism, whose last element, continues to maintain the structure of the basic type but enriched with a data son of a social dynamics, which represents the transition from a society based on the family to one whose constituent element is represented by communities that share the same problems and the same means to address them.

The next phase of development of the 'informal' dwelling in Villa 31, corresponds to the consolidation of existing buildings and the overlapping to the precarious house (which will be demolished then) with a frame of reinforced concrete that will form the basis for the next superelevation organism. At this point the possession of the lot is a certain fact and the architectural organism can develop and contribute to the economic growth of the family that is occupying it.

The first two elementary cells built are positioned almost always on the roadside and placed on one side of the fence. In this way it is possible to enable a passage that from an access both to the courtyard space and to the covered rooms of the house. The housing unit, at least in a first phase, not expects, for safety reasons, the direct opening on the public path.

The second phase sees the doubling of the previous structure so as to define a more private space directly facing the courtyard, and the other part of the housing unit open on the roadside. This area of the house will be allocated to trade or laboratories and workspaces.

The third phase corresponds to the moment in which the housing unit becomes a multi-family building through the building of a unit on the bottom of the fence, with the purpose of obtaining a house to lease or to give to sons who form new families. In the more populated areas, the internal division of the lots may continue until the establishment of units result of further internal split of the lot that uses a single elementary cell on the front and defines organisms similar to row house structure. In these cases the housing requirements exceed the problems related to the housing health forming organisms in part or totally devoid of external openings. The transition, from single-family lots to housing units able to accommodate more families, is possible thanks to the main feature of the organism: the courtyard type lives thanks to the open-air space around which are distributed the various environments of the dwelling. When the architectural organism is transformed into a multi-family unit the environments that previously belonged to a single unit, are connect so as to constitute areas of life for several families that share the distribution space of the previous mono-family house. As in Pasajes of Buenos Aires, also in the informal fabric these paths form semi-public or public spaces that distribute the units in the bottom of the lot. In cases of strong housing demand the described process generates such a pressures able to constitute connections between the public path and the inner housing units through private spaces, often open-air, making very important problems of privacy. In analogy with what happens in the 'formal' fabric process, the development of basic architectural organism, on one hand provides multi-family houses and on the other a vertical growth especially in the most populated areas. New stages of development, often contemporaneous with the described process, depend, as always, by the growth of the surrounding fabric and the increased housing demand. In this case, the unit will develop upper levels, starting from the elementary cells on the road, with a direct distribution from the street which avoids the use of the courtyard for the distribution of housing units on the upper levels. The vertical development also continues inside the patio, but only in cases of high-density urban fabrics and in this case the stair will be placed inside of the courtyard space.

Today walking the streets of Villa 31, but probably in the area of Guemes ten years ago, the constant element, main feature of the architectural organisms, matrix of the analyzed fabric, is the presence of winding staircases, or in some cases rung stairs, along the street in correspondence to each housing unit. These stairs represent one of the signs of the transformation in multi-family houses. Once you have defined the structure on the ground floor, it doubles the height of the reinforced concrete frame (ready for the raising of the structure) and builds more housing units on the upper floors which are generally used as houses to rent. Today the Villa 31 is one of the more established informal fabrics of the whole Argentine Republic, with buildings that come to have up to 5 levels (Amato, 2014).

From morphology to urban regeneration

Regeneration, renewal, revitalization, are just some of the concepts used to define an extremely complex topic as that of the transformation of strongly degraded contexts, in terms of physical, economic, social and cultural development, into proper urban neighbourhoods.

The interdependence of socio-economic factors with those more specifically architectural-constructive is indeed one of the crucial aspects of spontaneous settlements and, above all, one of the basic elements to the understanding and transforming of and contemporary informal city. Do not understand this aspect means to put our self at a 'different' level, far

from the reality that we want to regenerate. On the contrary, especially within spontaneous organisms the understanding of the socio-building logics that led to the formation of these tissues is crucial to achieving the same success of the project: the urban fabric is first and foremost expression of many other social, economic, cultural, 'tissues'!

The Villa 31, like so many similar realities, lacks of a network of sub-services: no running water, no electricity, no adequate sewers, it lacks of the minimum health standards. There is no road paving, actually it often lacks a clear distinction between vehicular and pedestrian spaces, as well as a clear distinction between public and private is not always evident. In short, it lacks all the elements that characterize a contemporary urban neighbourhood. Think of those elements according to a functionalist and technicist approach only makes us fall into the error previously mentioned, that of 'take the distances' from the reality that we want to enhance paving the way towards a likely failure. On the contrary, all these elements must fit within a 'socio-morphological' framework traced starting from the understanding of the strategies that have led, up to that moment, the formation of these tissues. In this way, each new element is able to 'tune' itself with the community living in that given context and which, in turn, is able to 'make it their own', being responsible for its functioning. It's always the community of inhabitants to have in its hands the fate of its district, especially in contemporary informal and semi-urban slums. Do not involve it, do not understand its settlement logic means to fail in our intent. These fabrics possess, in fact, a strong social density and an incredible building dynamism, both aspects of great importance when designing an urban 'regeneration'. These are the dynamic, vital, elements on which to build the new district. These are the 'forces' to use to actually regenerate an urban setting. Forces that, if misunderstood, will lead to the probable failure of any urban initiative but, if well understood, they may also constitute its foundation.

Paths, polarities, fabrics

Our first task was therefore to understand the socio-morphological structure of the Villa 31 in order to design its conscious regeneration. Paths are the tool that, perhaps more than others, allows us to understand and read the processes of anthropization of a given territory according to their 'structural aspects'. The more an environment is anthropized, the more the logics driving the formation of routes are accurate and precise. The less it is anthropized, the less its routes have a 'form' scientifically readable remaining in the boundaries of the subsistence routes and of immediate functionality. Paths that belong to the same logics of settling and therefore constitute a good basic structure on which to consciously read (and design) urban transformations. In Villa 31 is possible to identify three interrelated systems of routes. The first, most important, that we have called *matrix path* as the main route structuring the whole neighbourhood. It has a longitudinal trend, parallel to the railway tracks, which arises from the Buenos Aires Bus Station and, a little farther, from the Retiro Train Station. It is the only path characterized by the noticeable presence of commercial activities that characterize it as the backbone of the entire neighbourhood. Substantially orthogonal to the latter there is a secondary matrix path connecting the first one with the eastern tissue. This too presents small commercial equipment along its margins. The two main routes, structuring the new settlement are therefore the two major connection arteries with the existing context. This is not accidental because as we said, we are in a settlement phase where the 'streets' are paths of immediate functionality. It is along these two axes that the heights of buildings are over two floors above ground and it is along these axes that we find the greatest concentration of non-residential uses. A second system of paths, which we call *building paths* arise mainly from the Bus Station square and from the main *matrix path*. These are the routes along which the neighbourhood builds its urban structures. They are characterized by the dominant presence of the residence with commercial activity concentrated at the points of connection among the building paths and between them and the matrix paths. A third and final routes system concerns that broad network of lanes (*pasajes*) generated directly from the consumption of the courtyards of the first plant, when the patios

turned itself from a private family area to a collective semi-public ambit. They are paths deeply rooted in all courtyard fabrics when the increase of demographic pressure and the finite amount of building space leads to a need to increase the population density through the occupation, the clogging, the superfetation of all the available space. For this reason, this third routes system is of fundamental importance in the understanding of the 'socio-urban' tissues of the Villa 31 constituting the lifeblood of the entire building structure. It is in them that the daily life of the district take place, it is to them that the functioning itself and the identity of the informal settlement defer. At these paths corresponds a dimension purely residential except for some craft activities that can take place in what remains of the original courtyards and that are spread patchily across the fabric without a real urban logic.

"A city is a system in which all life, including the everyday life show a tendency to be polarized, that is to take place in terms of social aggregate, public or private. More polarization is exercised and closer is the exchange ratio between the public and the private and more 'urban' is the life of an aggregate from the point of view of sociology". (Bahrddt, 1966). It is not a coincidence that the vast urban historical iconography presents the city as an object enclosed by walls and exalted within towers and domes, sharply contrasted to an 'external' rural undeveloped, although often carefully organized. The view generally tended to identify the essence of the place fixing its special features in a high-quality 'characteristic image'. Those towers, those walls, those steeples, those domes, minarets and so on are what comes of urban polarities. They are responsible for coordinating the urban fabric; they are responsible for identifying the different urban communities by giving all citizens a sense of belonging to a single civil individuality. Polarities can thus be 'centralizing' or 'delimiting' an urban organism. In particular, civil and social most representative buildings were located, in the heart of the city or its neighbourhoods (the cathedral, the parishes, the Bishop's Palace, the Broletto, the market, the stock market etc.), while buildings with a specialized function (the city walls, the lazarettos, monasteries, military barracks, etc.) because of their higher dimensional space and because of their sectorial role within the civil fabric, tended to sit on the side-lines of the city, to occupy those urban fringe belts defining both the urban boundary and its points of exchange with the territory. There are two key elements that emerge studying the concept of urban polarity. The first is the dynamic relationship that is established between the polarities. The second is the relationship that develops between the polarity and the urban fabric. It is a relationship of reciprocity: tissue indicates the various possibilities of polarization available within itself, but it is the physical construction of the latters to allow that potential to materialize and the fabric to be realized. Like many other spontaneous contemporary reality, however, even in the Villa 31 we look at the total absence of urban polarities, of special buildings carrying out some recognizable public function within the tissue. Beyond the two major polarities formed from the Bus Station and Railway Station from which, we said, originates the same Villa 31, the district is, in fact, in a pre-urban settling condition in which the maximum level of specialization is given by commercial ground floors along the matrix route and the major connection points between the different road systems. This does not mean that they lack places with a strong polar vocation. On the contrary, the still directly utilitarian characterization of paths makes that along the latters those conditions of nodality and anti-nodality cited in the construction of a building fabric, are conducted freely and spontaneously. Conditions that lead to the identification of areas of higher (or lower) polar vocation in which it is possible, at a later time, to realise those public buildings around which to consolidate and identify the urban organism. Specifically, in the Villa 31 we can see how all the significant spatial dilatations of the tissue occurs along the main matrix path to connote an embryonic system of public spaces of unequivocal evidence. A system of 'squares', one might say, placed to enhance the role of the main matrix path as a great 'linear polarity' as a common threads that is a system of urban polarities able to structure and prioritize dynamically over time the whole neighbourhood. No coincidence that the only exceptions to the rule are characterized by whitespaces at eminently anti-nodal position with respect to the fabric of the Villa but directly related to the urban context according to a settling ratio typical of the 'peripheral polarities' whose specialist

function play a role in defining the building organism but, then, determining its exchange points with the territory.

The city is an organism made up of fabrics. Social, economic, cultural, environmental, fabrics leading the correct functioning of an urban structure. The more they are interconnected, the more that organism will be dynamic, versatile and able to answer to citizen needs and aspirations. To understand their 'form' means to understand their relational logics. The way in which these tissues interact with each other, in fact, expresses the way in which citizens live the city, expresses the way in which citizens transform the city through their daily actions. Understanding these logics, or rather, to understand the logical basis of these relationships and above all to understand their role in the definition of the urban fabric can be of considerable interest when studying the informal city. The reasons that support the formative process of its building structures, its tissues, are to be found within the dialectic 'nodality/anti-nodality' where the condition of nodality does not coincide necessarily with that of the centre and the anti-nodality does not necessarily correspond to that of the suburbs in the strict sense. It 'a matter of basic behavioural priorities and then of the hierarchies that are derived from these priorities. To these conditions of nodality correspond a greater specialization of the urban fabric that will go reducing as the distance from the nodality will increase until it will reaches the opposite condition of 'anti-nodality'. To the latter will correspond the absence of any specialization and the progressive fall of urbanity. The first is 'centre' and the second is 'periphery', the first is 'axis', the second is 'border' and so on. Through this dialectic urban fabrics will develop an integrated system of hierarchies, the more complex the more it will be the society of which they are an expression. In the case of the Villa 31, as explained before, urban fabric is characterised by the *Casa de Medio Patio* building type and its variations. Changes that follow the parallel system of hierarchies put in place by the urban fabric according to a dialectic of nodality and anti-nodality. So it is along the main matrix path that we find the greatest non-residential specializations of the ground floor. It is along this route and on the 'squares' that buildings implement, first, that process of multi-family transformation and that development in height of the type resulting from the rapid increase of population. A process of clogging and superfetation that, by now, involves most of the central areas of the villa but that gradually moving away from the 'centre' loses in specialization, characterising itself as a predominantly residential area, loses in number of stories, leaving the traces of original fences re-emergence with greater force, loses urbanity, blurring the transition between public and private, between built-up areas and open spaces. Putting together all these elements it has been possible then to come to the definition of a first draft 'structural (morphological) map' of the Villa 31. On this map we finally started to found our regeneration project of the villa.

The regeneration project

The most urgent problems of the Villa 31 regard the basic services of the everyday life (water, electricity, gas etc.), the drastic health conditions (no adequate sewers, no wc etc.) and the retrofitting of the buildings from both the structural and environmental point of view. For this purpose the rudimentary morphological map drawn in the analytical phase of the work has proved of great methodological utility. The vast array of open spaces, previously analysed and broken down into their urban potential, were thought as vocational areas for the distribution of all the sub-services networks. Spaces for which has been laid down the paving and the hierarchization according to their more or less nodal position within the urban fabric. So in the squares of the central spine was planned to build all those public buildings necessary for the everyday life of the neighbourhood. So in the two polar areas around the perimeter of the settlement, to the Port and to the Bus Station, two specialised public building were predicted to better connect the district to the urban context. So, finally, the green has been hierarchized following the same nodality/anti-nodality system according to a progressive decreasing of urbanity until to become a public garden or a sports equipment

(football field) in the most peripheral locations of the tissue. For the urban fabric have been planned the optimization of its spaces through the densification and the structural and environmental regeneration of its structures. Regeneration that must be done, however, according to the processual logics of the the *Casa de Medio Patio*, with the advice of engineers and building companies identified initially by the Municipality and through the activation of mechanisms of public-private financing. Apart from the services of first necessity, the fabric of Villa 31, in fact, must continue to grow and change autonomously according to the processes already started and clearly legible and where public intervention must be limited to a work of normalization. It's always the community of the Villa primarily responsible for the transformation of its district and its *civitas*.

The neighbourhood, however, is in constant and rapid expansion. For this reason it has been identified an area already partially occupied, towards the harbour, as the scope of a future expansion of the settlement. Expansion that, too, must take place according to the settlement logics already analyzed: starting from the hierarchical system of routes and public spaces. In particular, the second (building) and the third system of paths (local) are entrusted with the construction of the new fabric on which two new transversal paths (taking the role of secondary matrix paths) are interposed to connect the Villa 31 with the new context. Similarly, two new public spaces are planned in as many key positions to characterize the new building fabric. In this case needed more than ever because of the strong break of the district carried by the Autopista Presidente Arturo Illia of which we suggests undergrounding in order to permit the full conversion of the Villa 31 into a proper urban neighbourhood. The new fabric is then set according to the typical lots of the Casa de Medio Patio leaving the implementation of the process (building-superelevation-clogging) to private initiative with the advice and control of the municipality and through systems easy-access to credit.

Conclusion

La Villa 31 in Buenos Aires has been a good test to start a research project designed to assess the usefulness of the urban morphological tools in the regeneration processes of the contemporary informal city. Its location in a strategic position with respect to the historical and economic centre of the Argentine capital, between the harbour, the railway station and the compact fabrics of the consolidated city, its basic social and building stratification made the Villa 31 a very useful example in this direction. In particular, it gave us the opportunity to identify some key concepts, exportable to other case studies, around which to start building a morphological methodology for Urban Design.

Urbanization in the Ave Valley region: more than a sum of building projects?

Daniel Casas Valle, Nuno Travasso

Centre for Architectural and Urban Studies (CEAU), at the Faculty of Architecture at the University of Porto (FAUP). E-mail: dcv@cityeu.eu, ntravasso@arq.up.pt

Abstract. *In the diffuse urbanized pattern of the Ave Valley region (NW Portugal), a dominant urban morphology is absent. The fragmented and discontinuous urban form is a result of a layered urban landscape with a big variety of urban patterns. In contrast to compact urban settlements, this region has a very dispersed urban image. Not only have the physical and social conditions determined a relative small development grain, but also the planning system. In VN Famalicão – despite the availability of urban or project planning instruments (PU, PP) which have been the exception – the urbanization process has been highly determined by the sum of small loteamentos (since 1994, when the overall spatial municipality plan – PDM – was approved: one PU and one PP – global and detailed urban plan types - and 510 loteamentos). These are private urban developments regulated by a simple procedural regime almost without a specific urban regulation. The autonomous character of this urbanization mechanism has led to an uncontrolled or unplanned urban pattern for the whole, without a leading role from public administration. Central question is what is the result of the total of all individual building projects, which patterns and structure can be mapped? What is the spatial contribution to the public space structure (streets and roads) and public facilities (schools, sport, etc.), which design rules or urban regulation are applied? What kind of instruments are used to guide building projects, within the framework of the loteamentos? And what kind of instruments are included into the licence process of building projects for future use and maintenance?*

Key Words: loteamentos, private urban development, planning system, urban pattern, street

Introduction

“Facing the evident mismatch, it was needed to put aside the idea – typical of planning technicians – that the world is wrong when compared to abstract models which are right; instead of thinking that the problem may be that our theoretical and technical tools are not adapted to reality.” (Portas, [1986] 2006)

In the diffuse urbanized pattern of the Ave Valley region (Norwest of Portugal), a clear dominant urban morphology is absent. The fragmented and discontinuous urban form is a result of a layered urban landscape with a big variety of urban patterns. In contrast to compact urban settlements, this region has a very dispersed urban image. Such image is determined not only by specific physical and social conditions but also by the planning instruments and established daily practices that shape common urbanisation processes.

Although the diffuse urban landscape and the fragmented urbanisation process are since long recognized and studied (Secchi, 1984; Portas, [1986] 2006; Sá, 1986; Indovina, [1990] 2004; Neutlings, 1990), certainty is that there are still missing the means, models and instruments capable of guiding action in these territories, based on their own logics, in order to improve their legibility and intelligibility (Sieverts, [1997] 2003). Furthermore, Cavaco (2009) emphasises the existing of a mismatch between the planning system and the urbanisation processes.

In a context of vast and diffusely urbanised areas, where urban transformation is made by the sum of small autonomous private interventions the main question is: how to articulate such individual operations in order to create a coherent and intelligible larger urban structure?

The answer seems to point towards a planning essentially based on management (Bourdin, [2010] 2011), resting on a more continuous, procedural and reflexive practice (Ascher,

[2001] 2010), able to involve all willing actors (Jessop, 1998; Forester, 2008). Such practices will necessarily be the result of a bottom-up process, based on learning experience of local agents (Sanderson, 2009) and on a profound knowledge of the existing reality.

Figure 1. Urbanization in the Ave Valley region: more than a sum of projects?

More recent studies – namely in the field of urban morphology – seek such knowledge, by identifying and analysing the main elements that compose the complex structures of diffuse urbanisation (Boeri, Lanzani and Marini, 1993; Viganó 1999; De Rossi, 2009), and by understanding how they relate to each other in multiscale networks (Oswald and Baccini, 2003), and what are the logics and processes that shape each one of those elements (Mangin, 2004).

Following such path, this paper looks at the *loteamentos* of Ave Valley Region. These are private urban developments regulated by a simple procedural regime, and one of the main elements of this region's urbanisation.

Taking the municipality of V.N. Famalicão as a case study, *loteamentos* are analysed both as a process and as an urban morphology in order to better understand their role in the definition of this urban structure. Central questions are: What is the result of the total of single individual building projects to the overall spatial structure? What are the planning instruments, procedures and actors behind this process?

Urbanization in V.N.Famalicão

Adding fragments

During the last five decades, the Ave Valley Region has undergone an enormous urban growth, mainly shaped by the sum of small autonomous fragments, namely private urban development projects. Although this process followed an existing diffuse urban pattern²²⁴, it shows a *trend break* on the urbanization process, which is expressed by the transformation

²²⁴ The extensive diffuse urban settlement of this region has ancient origins. It has been referenced in 1762 by Castro, who described this whole region as a *continuous city* (I, 48).

speed, the type of operations, the building typologies and the planning procedures. The creation of *loteamentos* in 1965 is a key factor in this shift.

In the period 1970-2011, the population of V.N. Famalicão increased 49,2% and the total housing units rose 178,7% (Figure 2). This growth was caused by several reasons such as: internal migrations induced by new industrial jobs, improvements of living conditions and mutations on household types. Simultaneously, between 1976 and 2003, private house ownership was stimulated by a public program of subsidized credits and a series of fiscal benefits.

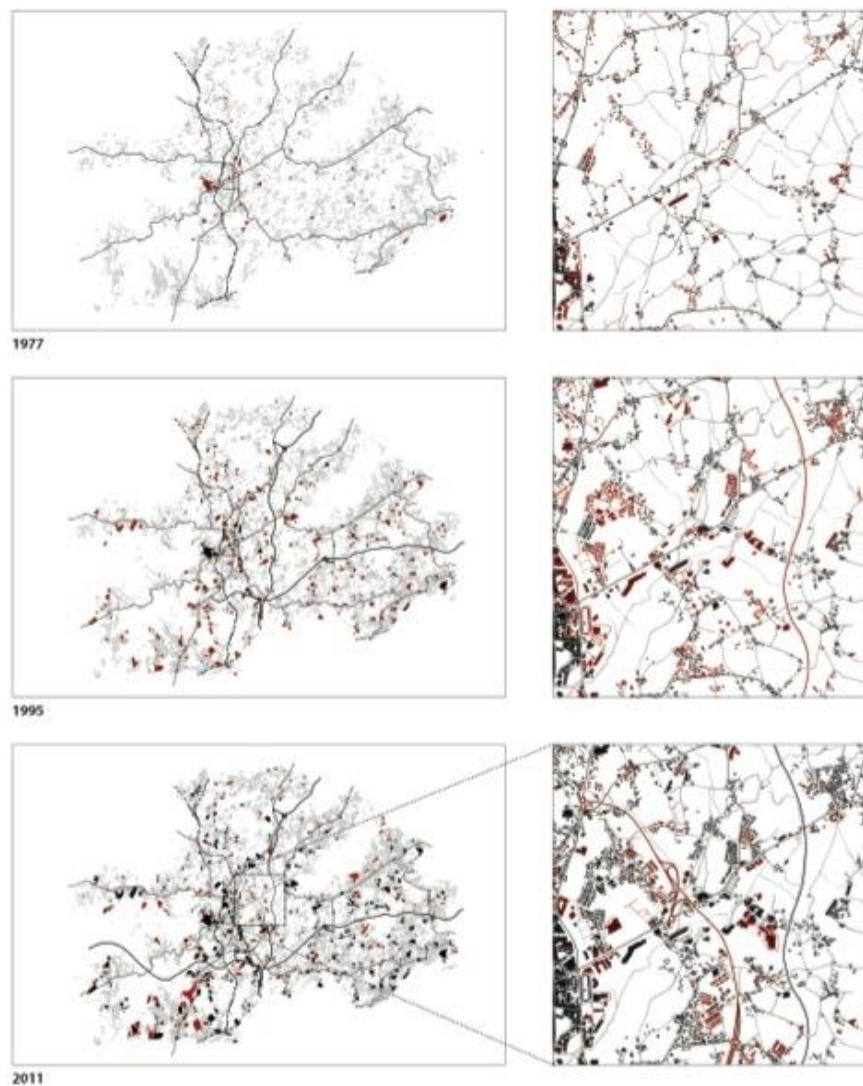

Figure 2. Evolution of the urbanisation in V. N. Famalicão.

The existing planning instruments and institutions were unprepared for such a sudden growth. In V.N. Famalicão, the existing plans were limited to the central town area and essentially linked to the design of specific public spaces and facilities.

The first comprehensive plan covering the entire municipality's territory – the PDM, *Plano Director Municipal* – was published in 1994, and it is still valid today²²⁵. This long or mid-term spatial plan established zoning (land use), generic rules (procedures, taxes, land use, typologies), new mobility lines and some special projects (as the town park). The plan

²²⁵ Presently, the PDM revision is in process. According to the national law, this should be updated every ten years.

enables large building possibilities in a vast area²²⁶, which was a common practice in Portugal. The logic was to provide excess of building area, to ensure low land values and, in this way, controlling housing prices, considering that housing production was completely dependent of the private market²²⁷. The plan does not go further in the creation of mechanisms to steer the urbanisation process, such as the definition of a yearly housing quote, target groups and their necessary housing demands, or a public housing policy. Furthermore, it does not include an implementation or execution programme

More detailed urban plans – such as PU, *Plano de Urbanização* and PP, *Plano de Pormenor* –, which, according to the Portuguese planning system, were expected to detail and shape the generic rules of the PDM (art. 87th, art. 90th, RJIGT), have shown to be the exception (Portas, Sá and Cardoso, 1998).

It is important to underline that, due to limited financial and technical resources, the municipality has no leading role in the urbanisation production, at least as a developing agent. Even more, it has no instruments to directly control land value (Correia, [1993] 2002). In practice, this means that the municipality has a restricted capacity to impose specific land uses or urban design²²⁸. Therefore, its key role becomes essentially to regulate and control individual private urban interventions.

In fact, the urban structure of this region is not the product of any overall design, but the consequence of a process of successive addition of autonomous private urban development projects. Even though these operations have been created through different procedures, the standard legal instrument is the *loteamento*. In V.N. Famalicão it is possible to recognize the major impact of this mechanism in the urbanization process (Figure 2 and 3). There, we can count a total of 1090 approved *loteamentos*²²⁹. Since the PDM was published, in 1994, while only one PP and one PU have been approved, a total of 488 permits for *loteamentos* have been issued. These correspond to more than half of all housing units licensed during the same period.²³⁰

Figure 3. All loteamentos of V. N. Famalicão.

²²⁶ This included the already urbanised territories in 1994, plus an important share of contiguous areas for future urbanization.

²²⁷ Controlling housing prices was one of the main purposes of planning laws and practices of this period, due to the fast urban growth and housing shortage, especially considering the almost absence of public housing.

²²⁸ This was particularly true in a context where urban growth was an objective to cherish. Not only because it was understood as a device and a sign of local development, but also because it was an important source of income for the municipality.

²²⁹ Although the large majority of these *loteamentos* are held by private developers, they include 17 initiated by the municipality, 15 of which for public housing.

²³⁰ Between 1995 and 2011 there have been licensed 16813 dwellings in new buildings (data: Instituto Nacional de Estatística). The *loteamentos* licensed during the same period comprehended 8662 dwellings (data: Municipality of V.N. Famalicão), which corresponds to 51,5% of the total licensed dwellings.

In this region, *loteamentos* are based on a small grain and historical irregular parcel structure. The overall image *loteamentos* have in common, is their significant autonomy or independence of developing logic (Figure 4), which is directly related to ownership and small grain of this urban territory (89,3% of the *loteamentos* are smaller than 2,0 ha). In general, the possibility to urbanise a certain area is always approached from the logic of one-entity-one-area. Though, in certain situations, the ability to develop larger areas through the collaboration of different landowners would probably increase spatial quality and economic value, this is not an established practise. By enabling building in such a vast area, the planning strategy made it impossible to create enough urban pressure to lead to bigger interventions. More than spatial reasons, the urbanisation is led by other factors such as economy, employment, demographics, public policies (taxes, subsidies), and the trends and dynamics of housing market.

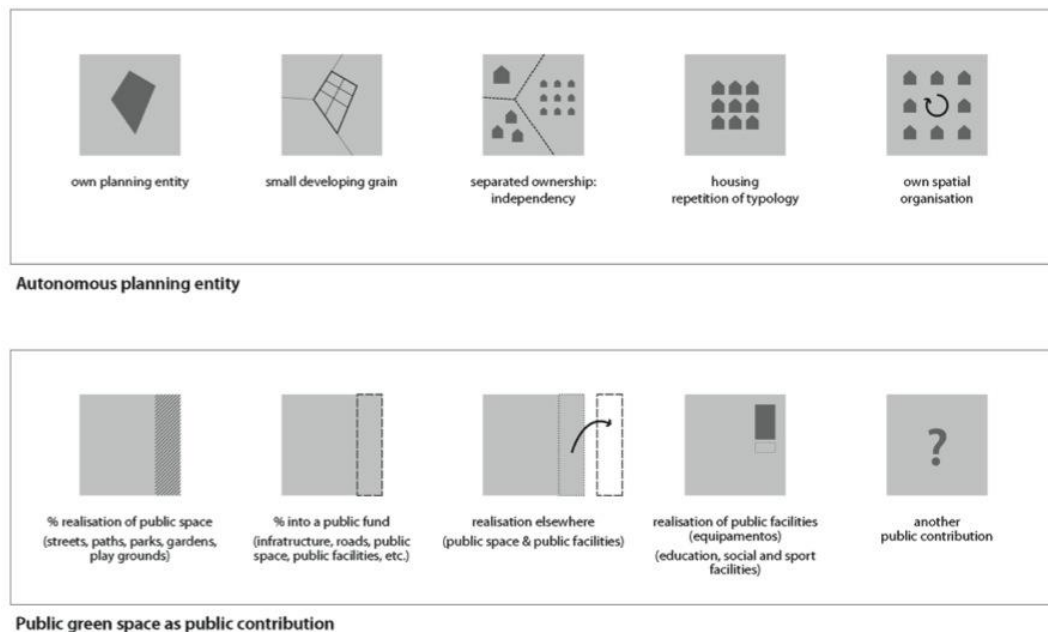

Figure 4. Planning logics of loteamentos.

Planning instrument

Loteamento: The creation of the legal instrument

In legal terms, *loteamento* is an urban operation that implies the division of the land in plots to be subsequently built (art. 2nd i), RJUE). It was created in 1965 (Decreto-Lei nr 46673) as a reaction to the proliferation of private urban development projects held outside any planning instrument or legal framework, which was a reaction to the fast growth of that period. By then, existing regulations were only applied to the few areas covered by urban plans; as the possibility of relevant urban developing outside central town areas was generally not considered, although common practise. In order to control these kind of private developments, the government created the *loteamento*, as a new legal instrument. For the first time, it was recognized to private agents the ability to urbanize the territory, and, in this sense, private developers were considered as substitutes of public entities, in their duty of urban developing.

Since 1965, the legal framework of *loteamento* has changed several times, pointing towards the creation of a simple and fast procedure. Such changes followed three main axis:

(i) Simplifying the procedure – Initially, obtaining approval for new *loteamentos* outside planned areas was difficult, time-consuming and uncertain, as it was decided directly by the central government. Hence, the tendency for developers to use other legal or illegal mechanisms in order to obtain the same effect. Seeking to oppose such practices, the government tried to ease and clarify the approval procedure. Nevertheless, the main change came with the implementation of PDMs, with which approvals of *loteamentos* became dependent only from municipalities. (ii) Limitation of alternative mechanisms – In order to escape the requirements of *loteamentos*' procedures, developers found other legal instruments that enabled land division, which became common alternatives. Several changes were made to the legal framework in order to abolish or limit those alternative mechanisms. (iii) Collective space – In order to guarantee a minimum quality of collective space and prevent the common practice of selling parcels before the completion of the needed infrastructures and public spaces, seldom left undone, new regulations have been created, defining minimum areas and conditions for such spaces and determining that parcels can only be sold after the completion of all collective spaces and infrastructures.

The legal procedure

Loteamentos made it possible that the urbanisation process is mainly based on individual operations, held directly and autonomously by private developers. Prerequisite for this is that they follow the general legal framework, and that their parcels are comprised *within* urban or *to-be-urbanised* areas according to the municipal plan.

The *loteamento* is a simple administrative procedure that can be initiated by any landowner by presenting to the municipality an urban scheme proposal for the intervention (street layout, public green space, parking, plot divisions, building footprints and typologies, functions and number of dwellings, etc.). In this process, the municipality has mainly a controlling role. It verifies the compliance of the presented proposal with the legal national framework and with the municipal plans and regulations. If the intervention is smaller than 4 ha, has less than 75 housing units²³¹ and is previewed to increase the population of its parish by less than 10%, no public consultation is needed.

After approval, the developer has to present detailed design proposals for all collective spaces and urban networks (water supply, sewerage, electricity, ICTs, roads, etc.). These are examined by the municipality, which consults all the responsible external entities. When these are approved and all due taxes are paid, the permit is emitted and the developer can start the construction of public space, including all the urban networks. Only after their completion and transfer to public domain is the developer able to sell the created plots or built units. The principle is that the municipality will be responsible of the maintenance of the public space.

Besides the needed streets and infrastructures, developers are required to create public green areas (Figure 4) and areas destined for public facilities. The needed dimension for this depends on the number of housing units or building area, according a general national regulation (Portaria nr 216-B/2008). However, such spaces are not always created. According to the municipality regulations, developers may compensate the public domain by creating similar spaces in other areas or by paying an equivalent financial contribution. This contribution should enter a public fund destined to invest in new public spaces and facilities, which in practice, is not a common practice.

²³¹ 75 housing units, according to municipal regulation (art. 10th §1 b), RMUE) which, in this particular point, is stricter than national general law, which considers a maximum of 100 housing units (art. 22nd §2 b), RJUE). The remaining conditions are similar both in municipal and national regulations.

Loteamentos and urban plans

Apparently, this simple and fast process came to substitute what was expected to be the role of PU and PP. Unlike *loteamentos*, those plans imply a fairly long and complex process, not only because of the needed steps to complete the procedure, but also because of the number of actors involved – namely several landowners, central government guidance, sectorial entities and mandatory public consultations. Changes to already approved plans are equally long and complex. Furthermore, whenever one landowner disagrees with the plan or does not wish to participate in its execution, all the process may simply block. Compulsory purchase is the established mechanism for solving such cases, but it implies financial resources public entities normally don't have.

More exactly, it is not relevant to compare the two processes – plan vs *loteamento* – as two possible alternatives (Figure 5). The *loteamento* is also the common mechanism for execution of urban plans. Therefore, it is possible to say that, in normal urbanisation processes, PU and PP are simply dispensable. PP and PU are only necessary if changes to the PDM are required (functions, building volumes or urban structure) or whenever the PDM explicitly states that a certain urban plan type is mandatory for a specific area. But these are clearly the exceptions²³².

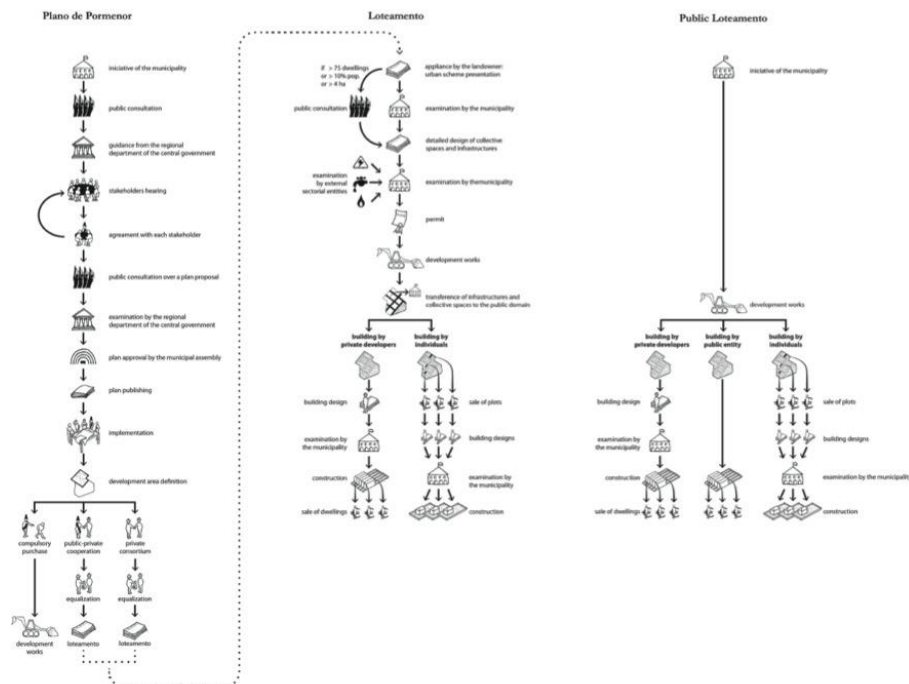

Figure 5. Comparison of planning processes between ‘urban plan’ (PU, PP) and loteamentos.

A procedural paradox

In principle, *loteamentos* are not recognized as a planning instrument²³³. According to the law that regulates *loteamentos* (RJUE), all urban structure and design should be determined by

²³² An on-going revision of national planning legal framework has the intention to change this condition. However it is still not possible to realize the real consequences of such revision.

²³³ This position is clearly stated in the on the law that regulates *loteamentos*: “*loteamentos should stop being understood as a mechanism for substitution of public administration by individuals in the functions of planning and urban management.*” (preamble, RJUE).

urban plans. Consequently, the *loteamento* should be understood as mere mechanism for their execution, with no relevant interference on urban structure, similarly to regular building licences. Such is the reason why the same law now regulates both *loteamentos* and individual building operations. This is a significant issue, as it points towards the idea that public entities have mainly a verifying and approval role²³⁴, instead of an active planning position. According to this stance, local public administration should not have the instruments or the ability to guide or affect the design of each private urban development, in order to make it a logic part of a coherent wider urban structure, for which the municipality is responsible.

This leads to an apparent paradox. On the one hand, the lack public financial resources and the absence of urban pressure – particularly on a context of diffuse settlement such as the one of Ave Valley – makes it impossible for public urban plans to establish as a standard mechanism for urbanization. On the other hand, the municipality has no means to interfere on the design of each of the fragments that, in practice, compose the overall urban structure without any clear coordination.

Daily practice

In spite of law intentions, the daily practice shows that the municipality has means to interfere. In reality, the actual law gives necessary margins. As mentioned, during the approval procedure, the municipality has the duty to examine if the presented urban schemes comply with municipal plans and regulations (art. 24th, RJUE). Such examination allows some room for interpretation²³⁵; especially considering that such plans and regulations are created by the municipality. Other mechanisms are at the municipality disposal. For instance, in V.N. Famalicão, in the case of larger projects, the urban management department of the municipality – responsible for the licensing procedure – usually asks the planning department to pronounce itself on the relation of the proposed development with its surroundings. The position of the planning department may then be presented as an external sectorial consult, and, in this way, reason enough for veto.

However, it is not as much a question of legal power, as it is of recognized legitimacy. In fact, from the analysis of several dossiers of licensing procedures in V.N. Famalicão²³⁶, it is possible to affirm that developers, in general, do accept municipality changes and suggestions in order to improve the urban scheme, without questioning its authority – obviously, after a process of dialogue and informal negotiation. Actually, this ability to directly negotiate with private developers has often been pointed out as one of the main instruments of the so-called *informal planning*²³⁷.

Nevertheless, this is the exception. Municipality's interference on the urban scheme proposals is usually very limited and restricted to the correction of clear and quantitative

²³⁴ RJUE clearly states the specific reasons for possible non-approval (art. 24^o).

²³⁵ The law that regulates the procedure clearly identifies the specific reason for possible non-approval (art. 24th, RJUE). However, it creates room for some interpretation. For instance by stating that an urban operation may be denied whenever it “*negatively affects archeological, historical, cultural or landscape heritage*” (art. 24th §2 a), RJUE) or by stating that “*The analysis by the municipality of loteamentos' proposals [...] should focus on its compliance municipal spatial plans, national spatial plans, [...] as well as on its uses and urban and landscape integration.*” (art. 21st, RJUE)

²³⁶ The presented conclusions result from an on-going systematic and detailed analysis of licensing processes of *loteamentos* in V.N. Famalicão. This study is part of the PhD research of one of the authors.

²³⁷ *Informal planning* is the common designation for the series of planning practices conducted by municipalities which are outside the established legal framework, such as negotiations with private developers or the development of urban design studies to guide urbanisation process which are not approved and have no value as plans. Several authors have studied such practices considering that, despite their lack of legal value, they tend to reveal higher effectiveness than formal planning system (Portas, Sá and Cardoso, 1998; Morais, 2006)

regulatory issues. In the few cases in which the municipality took a more active stance, the arguments supporting its suggestions were generally not evident, showing the lack of a clear, comprehensive and supported strategic vision for the spatial development of V.N. Famalicão. In this sense, it is noticeable the lack of municipal instruments based on spatial criteria, principles or qualities, than could be used in this phase, such as public space design guidelines or an overall maintenance strategy for public space. It was also possible to identify the absence of an established negotiation culture between the involved actors (no clear procedures, mistrust).

It is then possible to claim that, as João Ferrão (2011) argues, the main issue is not a legal one. It is mainly a question of *culture*. It is the way in which all involved actors understand and relate both to *spatial planning* and to the *territory* itself that determine the daily practices which shape the urban landscape.

Impact of Loteamentos in V.N. Famalicão

Looking at loteamentos

Acknowledging the impact of *loteamentos* in the urban landscape of V.N. Famalicão, it is clear they have contributed to the creation of a very dispersed and fragmented urban pattern (Figure 6). Analysing their spatial distribution there is no evident concentration related to any period or type, apart from a certain prevalence of collective housing typology in the central town area. *Loteamentos* are spread all over the municipality, following the existing diffuse pattern distributed along the valleys of the region and main road infrastructures, to which urbanisation is mainly linked. At a smaller scale, it is evident *loteamentos* have contributed to the creation of complex, discontinuous and fragmentary structures.

Figure 6. The sum of all loteamentos in relation with the urban areas of V. N. Famalicão.

Dynamics

As stated, urban growth of the Ave Valley Region directly follows market dynamics. Until the implementation of democracy in 1974, *loteamentos* had little presence in V.N. Famalicão. In 1974 there was a first production peak, corresponding to a total of 926 housing units²³⁸, followed by a profound depression in 1978 and by a second peak in 1981 (1027 housing units). From 1985 it is possible to identify a continuous and sustained increase until the year 2000 (1252 housing units), after which the number of processes clearly falls. From 2008, with the sub-prime crisis, the market has basically paralysed.

Figure 7. Licensed housing units, in numbers.

Figure 8. Housing typology in loteamentos (average housing units per year, for each period).

Figure 9. Developer category in loteamentos (average housing units per year, per each period).

²³⁸ Number of housing units contained in the approved permits for *loteamentos*.

During this period (Figures 7, 8, 9), different trends – related to typologies and procedures – can be identified. Key factors are the approval of the PDM and the introduction of professional developers. Before 1994, the most common projects were the ones initiated by individual landowners, who, most of the times, limited their interventions to plot division (with or without the creation of new public space and infrastructure) leaving building for future buyers. In such cases, single housing was the most common typology.

After 1994, the share of row houses increased enormously, becoming the most common typology for *loteamentos*. From 1994 to 2007, row houses and collective housing clearly dominated the growth process, which had a relevant impact on the urban landscape of the region, until then mainly dominated by the small grain of detached and semidetached houses. Such trend is correlated with the evident preponderance of private professional developers during this period. The introduction of this kind of developers had an effect on the dominant typologies, as they were normally responsible not only for infrastructure and plot division, but also for the buildings. It had also an impact on the scale and network type of the operations. Also, more non-residential *loteamentos* were initiated in period, because of the industrial zones established by the PDM. These *loteamentos*' types show a completely different urban design and morphology, primarily because of the different building typology and heavy road network destined to trucks.

In the last years, the involvement of professional developers has gradually decreased. Though private companies are still responsible for the major part of *loteamentos*, they are now a minority when considering the totality of permits for new housing units in the municipality – something that happens for the first time since 1998. Such mutation will probably have noticeable consequences on housing typology and on the processes of transformation of urban landscape.

Loteamentos: morphological typology

Case-study selection

For a more detailed morphological analysis of *loteamentos*, an East-West strip covering the whole length of the municipality is delineated to select a representative sample for residential *loteamentos* (209 *loteamentos*, ~19% of the total *loteamentos*) (Figures 10, 11, 12). It is a 1500 m wide strip along the axis of the regional road N206, covering different contexts: a more rural and dispersed area to the West, the central town area in the middle, and a more intense and diffuse settlement to the East.

The presented results are based on this sample. Main focus is on the contribution each *loteamento* has to a larger structure. In this sense, two scales were essential to map: the *loteamento* unit and the impact to a bigger area (sample). For this analyses GIS data is used combined with map and aerial photograph information. The base source for this research is the GIS database of the municipality of V.N. Famalicão. This database is further developed and extended by the authors for this article. In the last year, several fieldwork visits were made.

Relation of loteamentos to the overall structure

Essential *loteamento* aspects are: ownership, own accessibility, series housing types, and one single planning process. Therefore, *loteamentos* tend to present certain independence in relation to their surroundings: an autonomous spatial entity. Each *loteamento* introduces its own urban type (Silva, 2005) without clear or significantly transforming, adding, improving or adapting the larger existing context. However, the sum of all creates small and larger disruptions in the existing spatial structure, due to the introduction of big building volumes

and new typologies, clearly identifiable building clusters, or larger street space standards (Figure 13).

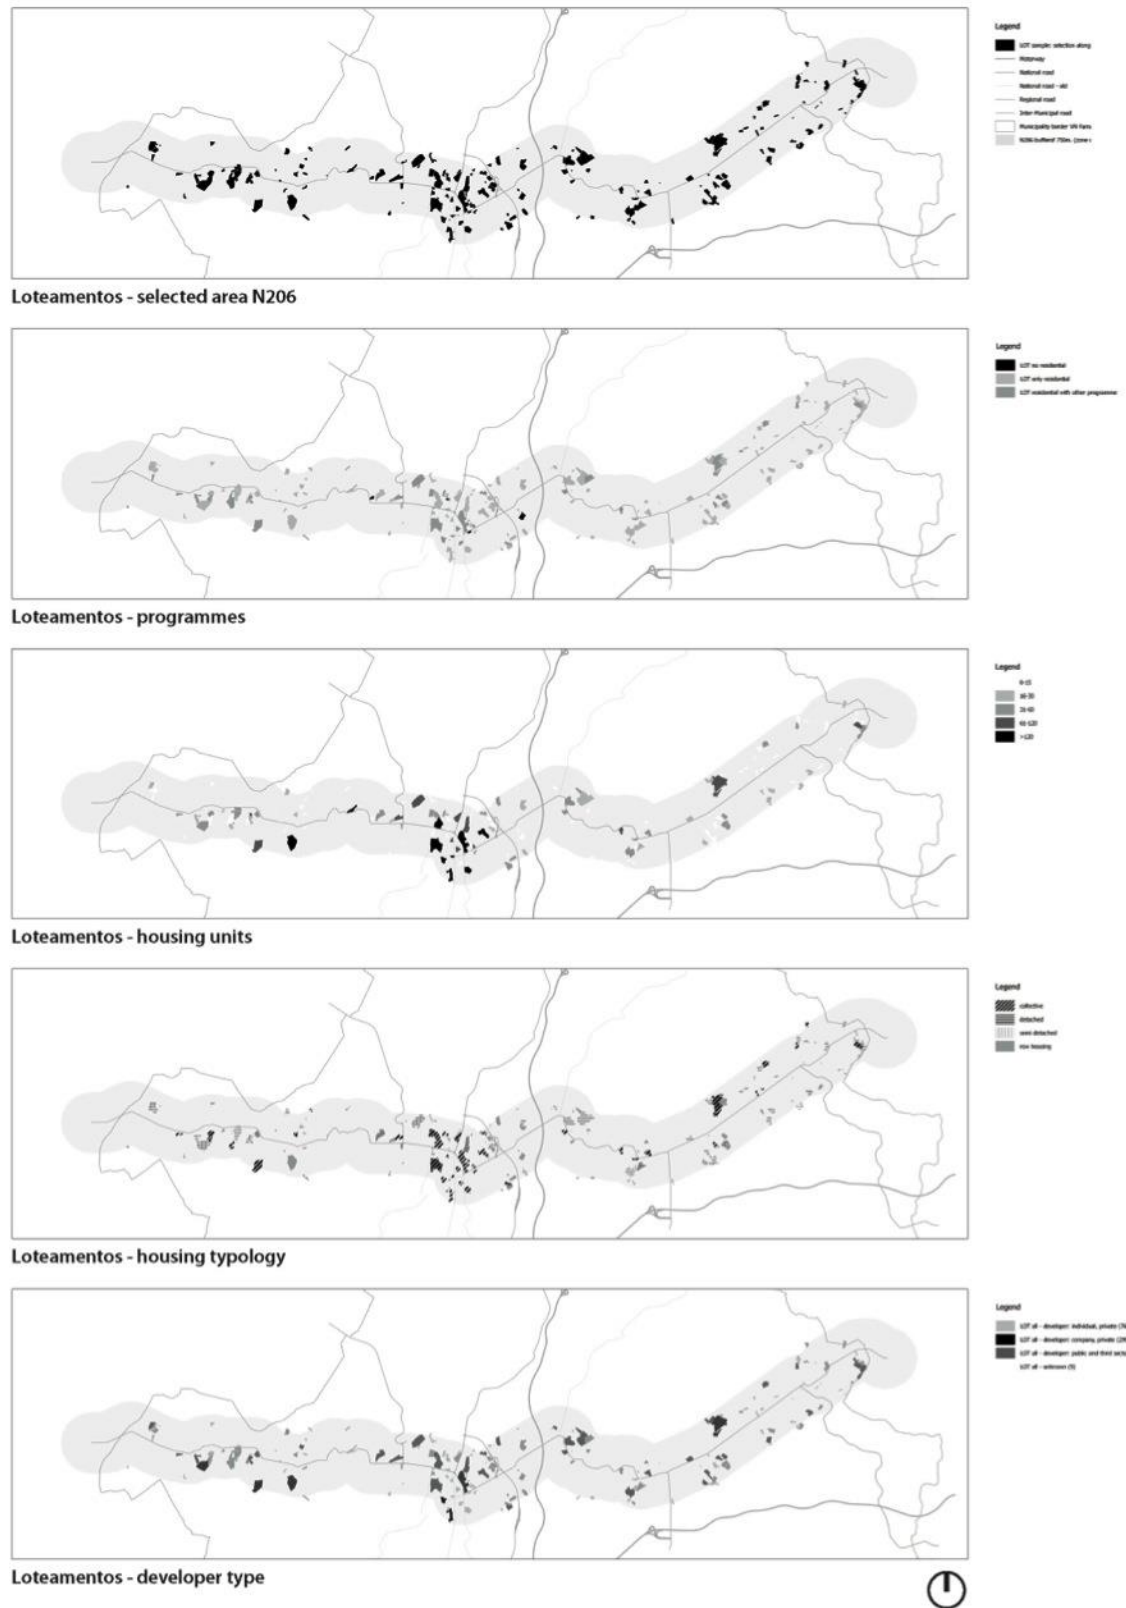

Figure 10. Sample of loteamentos 1 – programme and developer type.

Daniel Casas Valle, Nuno Travasso - CEAL/FAUP, 2014

Figure 12. Sample of loteamentos III – data.

Figure 13. Two examples of loteamentos – introducing new public space characteristics and building typology.

In order to better grasp in which way *loteamentos* participate on the construction of urban structure, the analysis focused on the *public contribution* given by each operation, namely looking at the proposed public space design.

Public contribution

In principle, each *loteamento* is a unique and autonomous 'urban product'. However, the ability to urbanise involves certain responsibilities towards the community and/or the direct surroundings. As mentioned before, developers have the obligation to execute all needed infrastructures networks and public space – namely public streets, a certain amount of public green space and areas destined for public facilities. After completion, these are transferred to public domain, shifting the maintenance task to the municipality. In this way, an important share of the public urban structure is created by the sum of private interventions.

Nevertheless, these are mainly quantitative demands – often even with a paid-off possibility – which do not take in consideration local spatial characteristics. Despite existing regulations, it is noteworthy the lack of public green space (only 37% of *loteamentos* sample), specific pedestrian areas such as sidewalks or squares (only 36%), or the use of trees in public space (only 30%). This gives an indication of the relative minor public contribution of the sum of all *loteamentos*.

Due to the lack of spatial, urban design or morphological municipal regulating instruments or guidance, the design is shaped by generic rules²³⁹, independently from specific contexts. Such rules determine the existence and dimension of elements such as sidewalks, parking lots and road lanes, creating new urban design standards that contrast with the existing thinner and more delicate structures. Public facilities are basically absent. Due to the limited dimensions of *loteamentos*, mandatory areas destined for public facilities are generally too small for buildings. Therefore, they are usually used for installing simple children playgrounds. In the few cases of larger operations, some parcels are transferred to public domain unbuilt, as developers are not required to actually build facilities. Parcels are then part of a municipal land stock, which maintain available for future necessities or opportunities of public domain. In order to include in the spatial analyses urban morphology aspects, two urban design features are distinguished: network type and public green space type. Both are key indicators of 'public space contribution'.

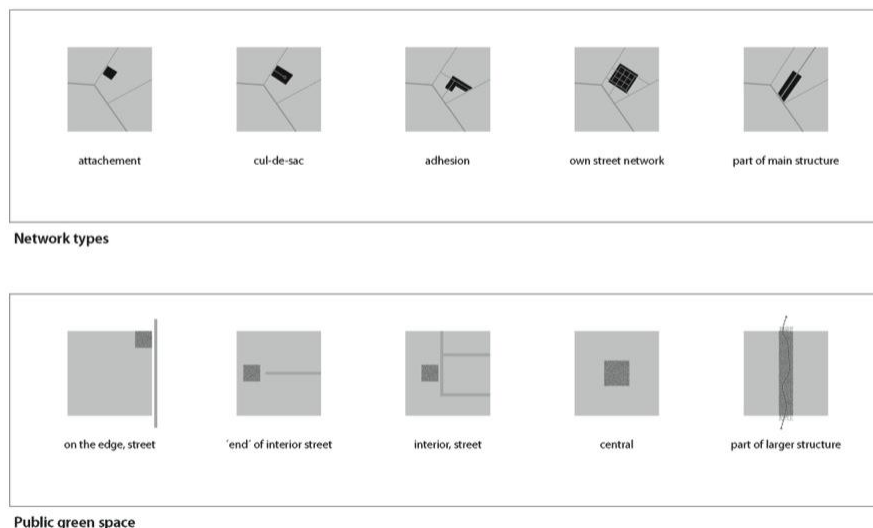

Figure 14. Network types and public green space types.

²³⁹ Portaria nr 216-B/2008 is a national regulation that determines the required areas for public green space, public facilities areas and parking, as well as the required dimensions for roads and streets. Such regulation is valid for all the country, unless it is totally or partially substituted by different rules by local spatial plans. V.N. Famalicão follows the national rules, which not include local specific aspects in order to adapt them to the spatial characteristic and qualities of each context. These regulations are further complemented by other national laws such as the accessibility regime (Decreto-Lei nr 163/06) that establishes in detail minimum measurements for sidewalks.

Network types

The relatively small size of *loteamentos* limits the possibilities of urban structure types. All *loteamentos* have a certain connection to the existing road network, also connecting to other urban networks²⁴⁰. In the selected area, five different network types can be distinguished (Figure 14, 15): (i) Attachment: *Loteamentos* that make use of the exiting street or road network; (ii) Cul-de-sac: *Loteamentos* based on new introverted streets; (iii) Adhesion: *Loteamentos* that create new streets connecting to the existing streets and roads, often improving local network continuity; (iv) Own street pattern: *Loteamentos* with a proper public street design with its own recognizable logic, normally with a specific materialisation, urban furniture and green space; (v) Part of the spatial structure: *Loteamentos* that directly contribute to the realisation of a part of the street or road main structure.

In general, *loteamentos* have little contribution to the construction of an overall continuous and intelligible street or road network. In fact, a total of 160 *loteamentos* (77%) have basically no contribution to such a structure (*attachment* or *cul-de-sac* types). 45 *loteamentos* create some local street patterns: some improving the local street network by introducing new connections and enhancing its continuity (no dead-ends), others introducing their *own street patterns*, which, in general, are embedded and connected to the existing street network. Only two *loteamentos* have a direct contribution to the main street network, both at the scale of the town of V.N. Famalicão. No *loteamento* makes a contribution to the main regional network.

Noticeable in various urban schemes of *loteamentos*, is the simple repetition of series of a housing typology, even if it does not fit easily into local spatial context or if it does not benefit public space quality. This has directly consequences to the network type layout, public and private gardens, and the connection with the surrounding. Specially, if there is no clear vision on the overall public space structure, including a maintenance framework and specific design aspects.

Public green space

Based on the position and access scheme of public green spaces – and considering their relation with different network types – five categories were identified (Figure 14): (i) Green space situated on the edge of the *loteamento*, facing a street; (ii) Green space situated at the end of an interior dead-end street; (iii) Green space situated in the interior of the *loteamento*, facing a street of the new network created by the operation; (iv) Green space as a central organizing space of the *loteamento*; (v) Green space designed as constituent part of a larger structure.

Similarly to the network types, it is here possible to observe that public green space has little contribution to the creation of an overall coherent urban structure – only in two cases are green spaces part of an existing or expectable larger structure – or even to the definition of a clear order for the *loteamento* (see example m and n in Figure 15). In the majority of the cases, they are small spaces, with no specific character or use, simply located in the areas of the parcel which are the most difficult to occupy with buildings. In this sense, they seem to bring little value to public space or to each operation.

²⁴⁰ This point is clear in the PDM, where it is stated that in order to be approved, a *loteamento* needs to be connected to the existing road and urban network by qualified links (art. 37th)

Management of public contribution?

These two features underline the aforementioned difficulty of the municipality to guide each project in order to make them part of a larger intelligible urban space. However, it is not possible to claim that this results from the lack of legal instruments.

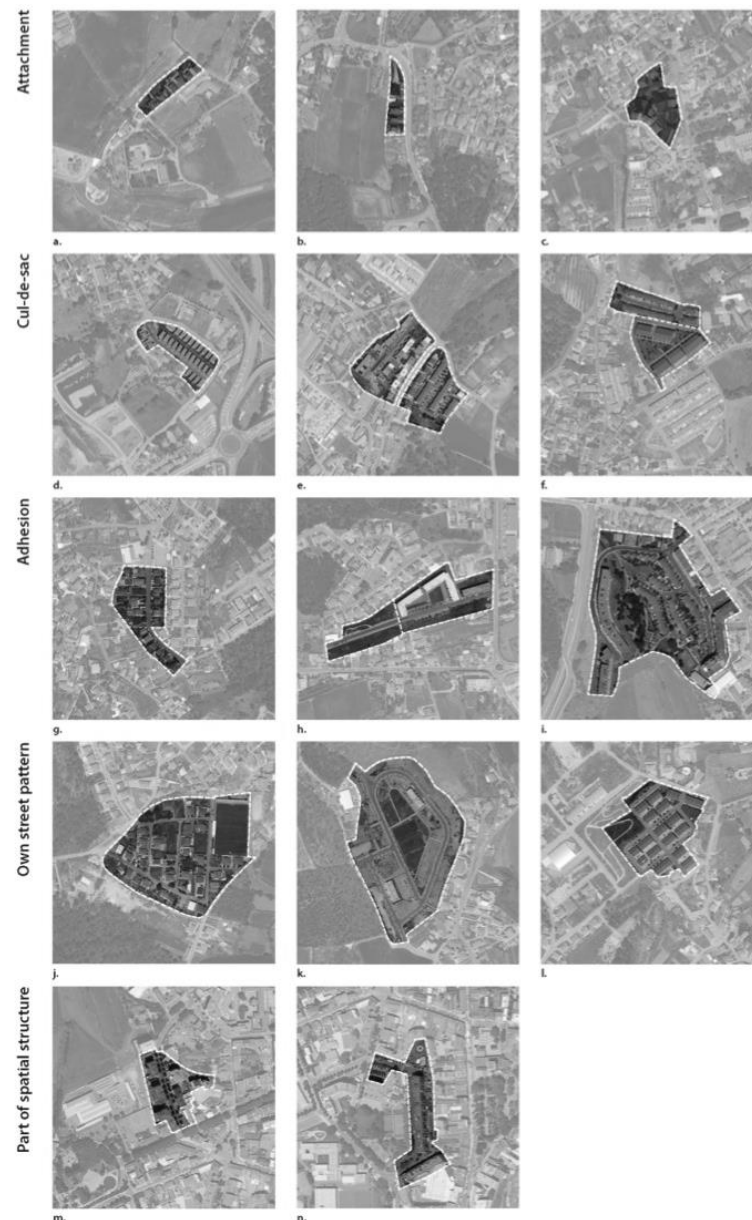

Figure 15. Network type, example of loteamentos.

Municipal regulations clearly state, “[...] all loteamentos [...] involving the creation of new roads shall be designed so that they rest on the existing network, establishing connections with unquestionable logic and urban justification and, whenever possible, avoiding dead-ends.” (art. 35º §1, PDM) They equally affirm that the “location, design and dimension” of public green spaces must “a) ensure an appropriate relation to its surroundings, enhancing the urban space where it is embedded; b) present adequate size and shape to the intended uses [...]” (art. 12nd, RMUE). However, the effectiveness of such regulations depends on the municipality’s capacity to interpret and implement it.

Conclusions

It seems clear that, in the Ave Valley Region, an urban growth shaped by the sum of autonomous small fragments has failed in creating an overall coherent and intelligible urban structure. *Loteamentos* are a key element of this process, producing various (new) urban typologies. And, in fact, generally, they do not contribute to the construction of continuous logic larger structures, mainly due to the lack of attention paid to their public space.

However, the main problem is not the existence of the legal instrument of *loteamento* in itself - although it is not an adequate instrument without overall spatial plans or visions. In reality, *loteamentos* seem to have revealed an important potential for the production of urban space, especially in a moment of a bursting real estate dynamics, and in which other planning instruments have shown to be incapable of answering to the existing demands. The problem rests mainly on the lack of efficient apparatus able to coherently connect each individual operation to other interventions and to its surroundings, in order to create logic urban structures.

Nevertheless, such lack of effective mechanisms is not primarily due to existing legislation or procedures. It is a result of the *spatial planning and territorial culture* of all involved actors, which determine daily planning and urbanisation practices. It is possible to identify a mismatch between, on one side, what different involved agents think planning and urbanization process *should* be, and, on the other side, the real dynamics, trends, logics and processes that daily shape the urban landscape. In parallel, there is also a mismatch between the planning system itself and its instruments (plans, design guidelines and regulations: formal and informal). Standardisation may have evident value when applied to large-scale integral urban plans. But when applied to scattered small urban developments, such as *loteamentos*, an incomprehensible mismatch between new small urban pieces and the existing spatial structure is produced.

In order to develop more effective planning practices, it is essential not only to recognize the specific characteristics and logics of *loteamentos*, but also to understand the impact the sum-of-all has to urban landscape. Much more important than possible changes to the formal planning system is to create an informal planning process based on local contexts and on local actor experiences. Instruments such as informal guidelines and spatial strategies – clarifying an overall vision but open and attentive to specific characteristics of particular territories – can contribute to the urban planning process in order to guide and define clear requirements in more open and transparent dialogue phase. This is not to substitute the formal planning system itself, but to give more room for local-based-solutions.

Integration of public spaces into the urban environment in case of Perm

Anastasia Kuznetsova, Svetlana Maksimova

Department of architecture and urban design, Perm National Research Polytechnic University. E-mail: nastyakyz@mail.ru, svetlana-maximova@yandex.ru.

Abstract. *The quality of urban environment is constructed not only with help of certain elements of it but with help of interaction between them. Historical buildings, nature elements (the river, the lake, the forest) should be integrated into public spaces of the city for the best perception of them. In this case public spaces have one more social function. The tool for planning is the a graphical method of a placement building mass (filled spaces) and open spaces. The open spaces are streets, parks, embankments, the yards inside the blocks, etc. Such morphological elements directly influence on the quality and comfort of urban environment and create the impression about the city as well. Interaction between open spaces and buildings takes place with help of facades of buildings. It is necessary to take into consideration the morphotype, condition of the facade, relation between the facade area and open space area, etc. Perm is the Ural city which partly has historical buildings of XVII-XIX centuries. The events of XX century contribute to lose historical shape and authenticity of the city. Seven rivers valley in the city are existing in bad condition and have no social and recreation functions anymore. The analysis of existing situation of Perm is occurring by the method of placement open spaces and research of facades condition for different morphotypes. It allows to find the ways of improvement of urban environment quality.*

Key Words: public space, morphotype, interaction, perception of the landscape, historical heritage.

Perm is a city on Ural Mountains of Russian Federation with the numbers of inhabitants about 1,023 millions, total area is 800 square meters. City is situated on the banks of the Kama river, stretched along it. The central part of the city has linear structure. Here are located historical centres and the main public spaces of the city.

Figure 1. The central part of Perm (Google maps).

Nowadays territory of the city crossed by 7 big valleys of small rivers, flowed to one of the biggest rivers of the Ural is Kama river. Historically, the city started to develop in the beginning of XVIII century on the banks of the Egoshiha river, where the territory of copper smelting plant was formed. To the end of XVIII - beginning of XIX century the center of the city gradually shifted to the banks of Danilikha river and continue to develop along Kama

river. Therefore the rivers are flowed in the central part of the city have not only recreational function but the historical meaning as well.

Figure 2. Perm 1910. Valley of the small river.

On the top of the valleys slopes diversity of the buildings are dominant: low-rise residential wood buildings, high-rise buildings, industrial buildings and empty spaces.

Herewith the valleys don't integrated to the city fabric, and are used for horticulture, don't connected by functions with the buildings around, are existed in abandoned condition. The accesses to them extremely uncomfortable and sometimes dangerous, or don't exist at all (Figure 3).

Figure 3. Valley of the small river.

Some watercourses of the small rivers are locked in the tubes and identify them as the water objects is not possible.

The embankment of the Kama river also is not in good condition now. Many years it had the scenic landscape and it was the adornment of the city and the favourite place for citizens walking. However, in the last time it has less popularity. Market makes faced interests of different departments and existing urban codes for railroad, river port, historical heritage (river station), electricity power line. In addition were formed the problems of bad conditions of entrances to this embankment from nearest streets: ruined ladders and subways are dangerous in the dark time of the days (Figure 4).

Figure 4. Subway led to the embankment of the Kama river.

As the result the main function of the territory to be a public space is blurred. The valleys of the small rivers and the embankment are the main and biggest components of green spaces of Perm (Figure 5).

Figure 5. Ratio of the green territory areas of Perm. Source: Strategic master plan of Perm, 2010.

Thus only the part of the green spaces are filled by functions. Big number of the small green areas and green yards is characterised by low quality of accesses, don't clear function, low activity of use. There is not infrastructure for physically disabled people. There is not the full recreation function.

Figure 6 shows the use of graphical method of two main elements of urban environment placement: the mass of buildings and empty spaces to define the problems and the ways of transformation the territory. One of the first who begin describe and search the relations between built and open spaces was Camillo Sitte.

Open spaces are the yards inside the blocks, streets, embankments, etc. These morphological elements directly influence on the comfort and quality of the urban environment and form impression about whole city. Interaction of open spaces with the mass of buildings is realized with help of the facades. Here are considered the morphotype of the building, its condition, relation between the area of façade to area of open space, and other parameters.

Figure 6. Open spaces of Perm (empty spaces are marked by grey, the main recreation areas are white).

The method of open spaces placement allows to analyze urban fabric in criteria: define existing functions of public spaces; location in relation to public spaces in city and local levels; accessible; connectivity of public spaces; possibilities to form of the public spaces system.

Figure 7. Placement of green spaces of the central part of the city and the main streets are connected them.

The second part of research is the analysis of facades which is allow to define presence of the visual connective between public spaces and buildings around. The visual links are created in depending the way of looking is going in between buildings and the main facades are located in relation with streets and open spaces.

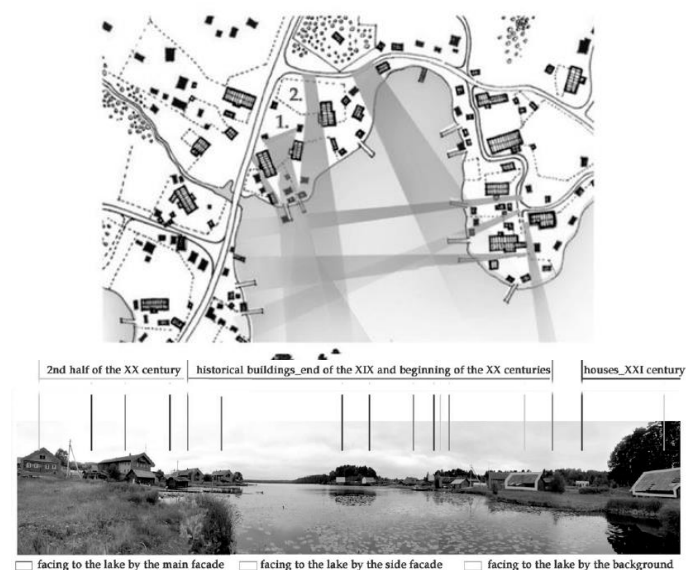

Figure 8. The example of defining of the visual links.

For example, the embankment provide good visual connectivity with the park near Art Gallery and the Gogol garden. (Figure 9, 10)

Figure 9. The view from the park near Art Gallery to the greenery of embankment

However, these territories have different quality: good condition of one territory is not continue in other green area with absent landscaping.

Figure 10. Parks are connected with the embankment.

Conclusions

Morphology of the buildings of the peripheral Russians cities became more blurred. Buildings and cars displaced people, nature and the public spaces.

Perm has unique resources of recreation spaces which are nowadays don't consist full functions of public spaces and recreation. In the city which has a lot territories for winter sport activity inhabitants have to go 40 km for skiing. The summer create big traffic to the banks of Sylva river (30-60 km outside the city). All these are existing in the same time the water resources in the center of the city don't using at all.

The transformation of the small rivers valleys have to starts from the back the first view of it, the nature landscaping and after has to be in harmony with the transformation them to public spaces with certain functions. Unify it in the urban net of the public spaces with help of pedestrian ways, bicycle lines, visual connectivity, providing the accesibility with help of improvement of the paths and roads, creating of places for street celebrations, open-air games, constructing of the playgrounds and grounds for the dogs. All of them will improve physical and visual links between public spaces and green areas of the city. The perception of the city will be changed in minds of inhabitants. The territories of the city which are now have a potential but don't used will be full of life.

A planning method of identifying viewing spots and area for landscape control by utilizing spectator's experience of a Japanese traditional festival

Daichi Yamamoto¹, Susumu Kawahara²

¹ Department of Tourism Science, Faculty of Urban Environmental Sciences, Tokyo Metropolitan University, Japan, 1-1 Minamiosawa Hachioji-shi, Tokyo-to, 192-0364, Japan. ² Graduate Schools of Urban Environmental Sciences, Department of Tourism Science, Tokyo Metropolitan University. E-mail. yfmr1104@yahoo.co.jp, ssm.kawahara@me.com

Abstract. *We present a practical a planning method of identifying viewing spots and area for landscape control by utilizing spectator's experience of a Japanese traditional festival. To realize these aims, viewer's favorite photographs of "festivalscape" are analyzed in a case study of Kibune festival, a traditional Japanese festival held in Manazuru Town, Kanagawa. This study recognizes three categories of "festivalscape," namely, the viewing location (Viewing spots), the viewer's target (Performance of the festival), and the wider landscape (Background). In this study, we identified three popular viewing spots examined the landscape viewed by spectators at those locations. Also, The most commonly viewed area was failed in comparison with landscape control area for festival compiled by the Manazuru planning authorities. These results located areas that should be preserved or enhanced for a more pleasant viewing experience during the festival. Our method is attractive because it can be easily implemented by non-specialists, uses data acquired from ubiquitous, low-cost digital cameras and smartphones, and is versatile. This last feature renders the approach applicable to any region with a traditional history, bordering seas or with panoramic points.*

Key Words: *Japanese traditional festival, Festivalscape, Viewing spot, Landscape control, Viewer's favorite photographs.*

Introduction

Tangible landscape control, which unifies the heights of buildings and facades in townscape or highlights landmark features, such as castles, towers, and mountains, has been embraced worldwide. In contrast, landscape control based on intangible features has remained underdeveloped. Such intangible features are rooted in tradition and local lifestyles and constitute the living and cultural landscapes. Japanese traditional festivals have been globally recognized as an intangible cultural heritage by UNESCO (2014).

This exploratory paper aims to develop a planning method of identifying viewing spots and area for landscape control by utilizing spectator's experience of a Japanese traditional festival. As a case study, the method is applied to enhancing the experience of spectators at the Kibune festival, a traditional Japanese festival held in Manazuru Town, Kanagawa.

To realize these aims, the study presents a series of viewing spots favored by spectators and landscapes that attract viewers' attention. This information is obtained to analyze viewer's favorite photographs of "festivalscape".

This study recognizes three categories of "festivalscape," namely, the viewing location (Viewing spots), the viewer's main target (Performance of the festival), and the wider landscape (Background).

Manazuru Town is located on the Manazuru peninsula of southwestern Kanagawa prefecture. The cone-shaped terrain faces Sagami Bay and projects toward the sea. With a population of approximately 8,000, Manazuru Town is a prosperous hub of fishing and stone industries.

The Kibune Festival is a portable shrine that carries a god by ship through the Manazuru Port. The origins of the Kibune Festival are intimately linked to the town's historical

background. Since the early modern period, Manazuru locals were mainly employed in fishing and in the mining and marine transportation of stone. Because the ships built for fishing and stone transportation were very small and sophisticated technologies and machines were lacking, people were regularly exposed to natural dangers. Therefore, people offered prayers for safety and plentiful fishing hauls and strongly appreciated the peace and security of their everyday activities.

From this background emerged the Kibune Festival of Manazuru Town.

Figure 3. A “festivalscape” of Kibune festival.

Landscape planning of Manazuru

This study aims to clarify the current situation and landscape planning problems of the “design code of beauty” aspect of the Kibune Festival of Manazuru.

To this end, I bibliographically surveyed the “design code of beauty” and interviewed a representative of the Manazuru Town Planning Division.

Manazuru Town was not exempt from the high developmental pressure that has altered Japan’s infrastructure since the late 1980s. Manazuru Town is a commutable distance from the Tokyo metropolitan area and is renowned for the quality of its natural environment.

In order to resist development beyond a human-scale landscape, Manazuru Town introduced the “design code of beauty” rule to promote creative urban designs and landscaping appropriate for a small town. The “design code of beauty” is based on the “pattern language” concept proposed by Alexander (1994), a positional design algorithm for representing high-quality regions. The algorithm locates suitable landscape grounds from 69 keywords. In applying the algorithm to Manazuru Town, the term “Festival” is included as a keyword.

Landscape planning in Manazuru has relied on qualitative assessments of attractive buildings, such as “design code of beauty,” for 10 years. Furthermore, after the landscape by law was enacted in Japan in 2004, Manazuru became the first township to specify administrative organizations and undertook quantitative landscape planning in January 2005.

To control its landscape, Manazuru Town has adopted a color standard that quantifies the festival by the Munsell value of the plan. During the festival, the port is dominated by vivid red ships. Consequently, the external walls of buildings in the Manazuru Port district, which define the background of the festival, are set to be brighter than other Manazuru districts to emphasize vivid red ships. Thus, an advanced landscape planning approach has been adopted for the Kibune festival.

On the other hand, a line of demarcation for color control area is obtained by utilizing land use, that is, basis for this standard is not intended to be reflecting the spectator’s perspective. It was recognized that spectators’ perspectives are dynamic, and that current measures to enhance viewers’ experience may alter in future. Therefore, the planning seeks to create favorable viewing spots for the festival and to increase the range of viewing perspectives.

Data Collecting Methods

Two surveys were conducted to obtain the required data for analysis.

In the first survey, preferred festivalscape views were derived from viewers’ favorite photographs captured during the festival. Photographs were collected from three sources.

First, 250 viewers selected by random sampling were requested to photograph the marine parade and e-mail their five best shots of the festivalscape. This approach yielded 39 photographs from 10 viewers.

Second, 13 high-quality festivalscape photographs entered in Manazuru photograph contests targeting various categories, such as historic sites and nature, cityscape, food, festivals, events, and people, were collected.

Third, we conducted a web search of the phrase “Kibune Festival space Manazuru” and selected a blog article on the Kibune Festival from the sites returned by the word search. This approach yielded 43 photos posted on 26 blog sites.

Collectively, we obtained 81 high-quality photographs of the marine parade festivalscape.

The second survey focused on the action records of Kifune Festival spectators. On July 27 and 28 in 2013, 10 investigators tracked the progression of the Kifune Festival and recorded its movements on a map. Moreover, the procession was captured by video cameras operated from three fixed points overlooking the entire Manazuru Port. To maximize the recording time, the photographing direction of the video was altered to follow the dynamic movements of the audience.

This survey revealed that almost all viewers distributed along the waterfront line moved around relatively freely while photographing the event.

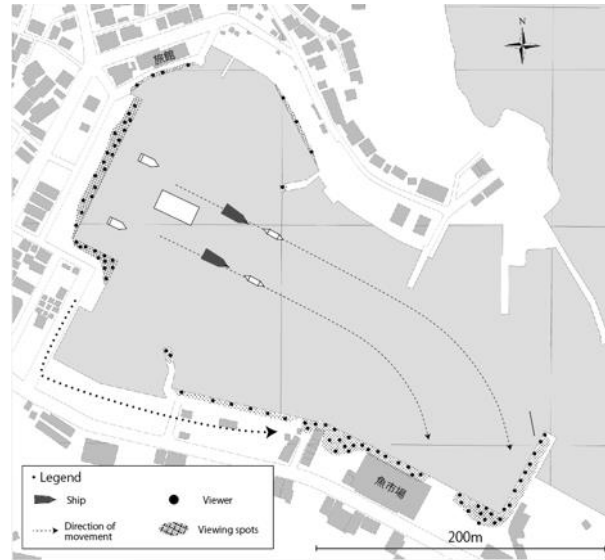

Figure 4. Results of spectator action record survey.

Best-photograph analysis of festivalscape

Favored viewing spots

The 81 photographs obtained from the photographic survey were analyzed with respect to viewing spots and cityscape.

The first analysis extracted several favored viewing spots from the landscape elements in the 81 photographs.

Process 1: The photographs were vertically bisected by a line defined as the central axis. Points of intersection between buildings and the uppermost and lowermost parts of the central axis were designated as Points A and B, respectively.

The density distribution of Kibune festival visitors, captured by the fixed video cameras, revealed that viewers remained along the waterfront of Manazuru Port. Thus, we extended a line through Points A and B in the direction toward the waterfront line. The intersection of this extended and waterfront lines were labeled as Point C.

In addition, the direction of the line joining Points C and A indicated the eye direction of the viewer, and the range between Points A and C decided the photographing area.

This process was completed for all 81 photographs of the festivalscape collected in the survey.

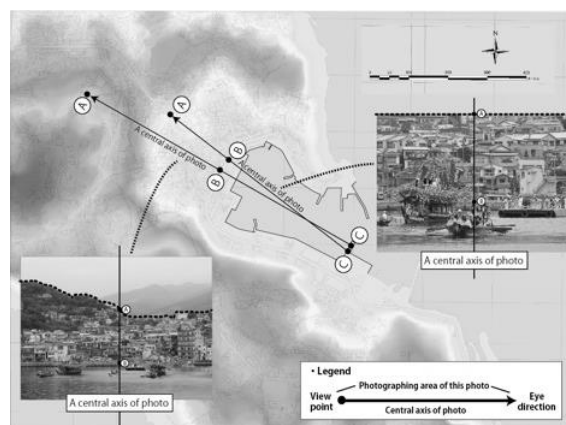

Figure 5. Implementation of Process 1.

Process 2. Based on land use and spatial continuity, the waterfront areas of Manazuru Port were classified into 10 regions and labeled Area A to Area J, each with its longest side extending to a maximum of 100 m.

Within each of these areas, the degree of the integration of viewpoints was acquired by dividing the number of photographs with viewpoints contained in the area by 81 (the number of photographs acquired).

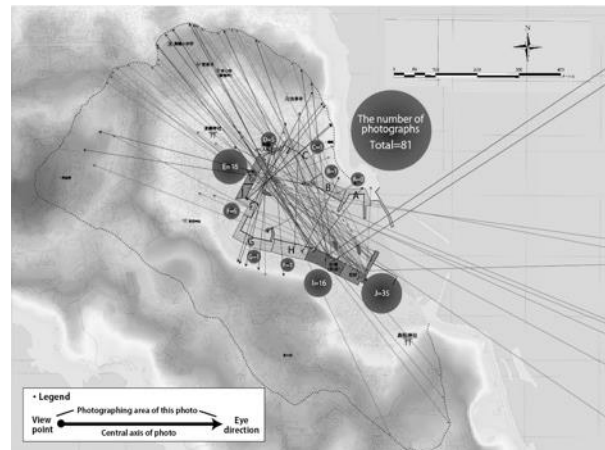

Figure 6. Implementation of Process 2.

Areas E, I, and J showed a high degree of integration, being observed in 14, 16, and 35 out of 81 photographs, respectively. Therefore, these three areas are identified as the favored locations for viewing the festivalscape in action and are expected to enhance the experience of viewers visiting the Kibune festival.

This result is likely affected by two factors: the parade route of the main target (the ship) and the visibility. The viewing values of Areas E and J may be linked to their proximity to the start and end points of the parade route, where viewers tended to congregate. In addition, the field of view in the southeast and northwest directions opens into Manazuru Port owing to the cone-shaped terrain projecting into the sea.

Extraction of important cityscape

Subsequent study focused on the backdrop landscape of the festival.

Because the festival is viewed against a background of buildings, Manazuru Town has formulated a color standard for landscape control.

However, a line of demarcation for color control area is obtained by utilizing land use, that is, basis for this standard is not intended to be reflecting the spectator's perspective.

So, to clarify important cityscapes that should be preserved, cityscapes that frequently appeared in the 35 photographs acquired from Area J were analyzed as a case study. The aim was to determine the section of cityscape most commonly encountered by viewers' eyes.

Process 3: The analysis focuses on a panoramic shot acquired on a sunny day on November 27, 2013. The panorama extends through 90°, sufficiently covering the city area from the midpoint of the waterfront line in Area J. The camera that acquired this image was affixed at 160 cm above the ground, the approximate height of a man's glance.

The acquired panorama covers almost all of the cityscape regions visible from Area J.

Process 4: In this analysis, buildings occupying the four corners of a photograph collected from Area J were extracted and labeled Building 1 to Building 4. The four buildings are interconnected by straight lines, which delineate the cityscape background of the festivalscape most commonly visualized by viewers.

The background cityscape observed by many viewers was identified by projecting the

delineated cityscape on the panorama and overlapping each area. For this purpose, Buildings 1–4 in each of the 35 photographs taken from Area J were identified in the panorama. The matching buildings in the panoramic view were connected by straight lines in all 35 photographs.

At the completion of Process 4, the most commonly viewed sections of the cityscape are indicated by dark colors.

Process 5: The obtained chart was divided into square grids of approximately $5\text{ m} \times 5\text{ m}$. The grid dimensions were based on the minimum size of the photographed buildings. If the projected areas covered 50% or more of the grid, the covered grids were counted, divided by 35 (the number of photographs acquired from Area J), and multiplied by 100. The result expressed the degree to which viewers focused on that area of the cityscape.

The numerical results were classified into four viewing frequencies ($\geq 50\%$, $\geq 40\%$, $\geq 25\%$, over 0%). Process 5 reveals how a background is observed from a viewer's elevation. Landscape planning, such as designating landscape preservation area, requires a ground plan. To solve this problem, buildings included in areas of high visual interest (40% or more) were extracted by the visual observation of the locale and painted on the residential quarter chart.

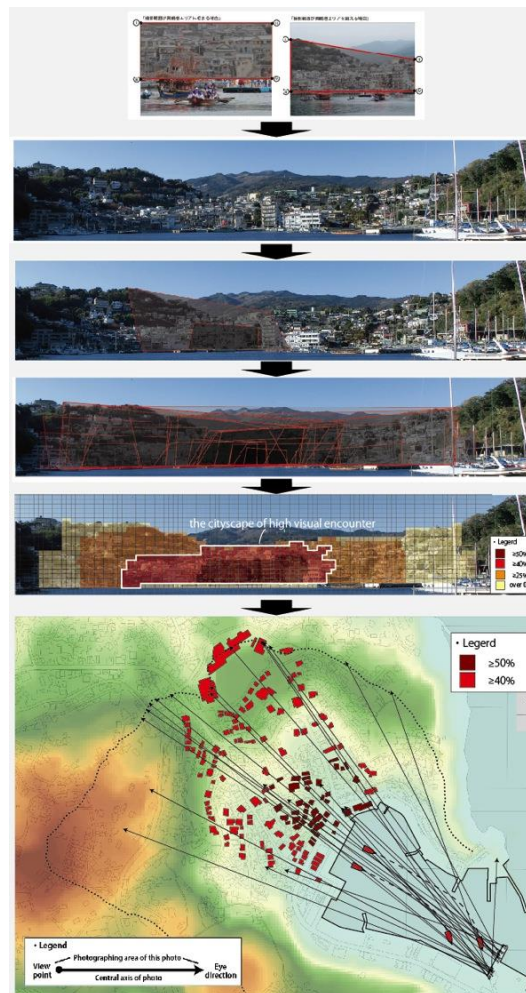

Figure 7. Implementation of Processes 3–5. The thick white line in the central panels delineates the cityscape of high visual encounter.

The chart with the painted buildings presents a symbolic landscape of the Kibune festival, revealing the background cityscape most commonly viewed by festival spectators. Thus, these buildings should be earmarked for landscape preservation.

Conclusions

This paper presents a method of identifying favored viewing spots from photographs of the festivalscape, based on landscape features along the central photograph axis. By dividing the number of viewpoints contained in designated areas by the total views of the festivalscape, three areas of favored viewing (Areas E, I, and J) were identified.

We consider that cityscapes most commonly viewed by festival spectators should be preserved because these areas frequently appear in spectators' photographs. These results can guide the current situation of landscape planning in Manazuru Town.

The most frequented viewing areas, I and J, should be maintained as favorable viewing spots by improving the land use of their backdrops. This is especially relevant to Area J, whose background encompasses a vacant "no entry" zone.

In addition, the extracted buildings mentioned in subsection 4.2 were compared with the color-controlled cityscape rendition of the Manazuru festival clarified in Section 2.

The comparison highlighted the need to accommodate more of the spectator's perspective in district planning. In particular, the Manazuru primary school situated high above the Manazuru port should be included as a landmark in the controlled district.

Figure 8. Areas I and J should be maintained as viewing spots.

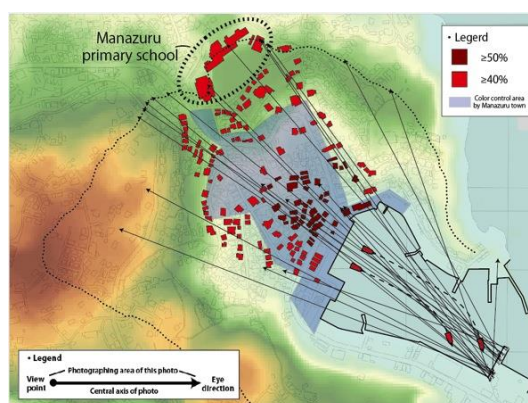

Figure 9. Extracted buildings mentioned in subsection 4.2 superimposed on the color-controlled cityscape version of the Manazuru festival.

The proposed method makes three useful contributions to district planning.

First, the method is easily administered in practice. High-quality photographs that provide the underlying data are easily retrieved from photograph contest archives. At present, anybody can capture images on digital cameras and mobile phones. With these technologies, which have become ubiquitous, viewers can essentially capture events, such as festivals in action, providing a wealth of data reflecting the viewpoints and needs of numerous viewers at

low cost. To narrow the data sources, photography contests on themes, such as “Landscape and Festival,” could be held.

Second, the analytical procedure is easily implemented by non-specialists, as it requires no specialized equipments or analytical techniques that must be learned beforehand.

Finally, because traditional festivals are held throughout Japan, this method provides an effective support tool for landscape planning around regional characteristics. Moreover, the method is applicable to any region with a traditional history, such as sea-facing bays or slopes that provide ideal panoramic points.

In summary, we present a versatile and practical approach to landscape planning that identifies both important viewing spots and area for landscape control. Such planning will certainly enhance the viewing experiences of spectators at Japanese traditional festivals.

Urban form and orientation in urban space

Anna Agata Kantarek

Faculty of Architecture, Cracow University of Technology
31-450 Kraków, ul. Ułanów 28, Poland. E-mail: akanta@poczta.onet.pl.

Abstract. *The question is about developing research disciplines based on human abilities of perception in the spatial reality of a city and referring them to urban morphology and typology. This also means posing a question about human orientation abilities in urban space nowadays. Urban structure and spatial legibility relation is extremely important. It is possible to formulate orientation codes of the urban form (the own codes of a form, signaling codes, mass transmission codes and other codes incorporated in culture) and find determinants which could define the notion of orientation of the balance in the urban space as a criterion of Urban Form.*

Key Words: urban space; space orientation; codes in urban space; urban meaning; urban signs

Thinking of spatial orientation as a significant aspect that determines the form of a city is obvious and yet very often neglected when it comes to the designing of the form and its content and implementation decisions.

The book "On Orientation in The Space of The City"²⁴¹ deals with the realities of the urban form perception nowadays. It develops the theme of orientation in the space of a city as a stage of developing such awareness of the city and acquiring such habits or skills of purposeful movement that would make other activities possible. Thus the quality of orientation plays the role of a determinant of other aspects of the life of man and the community.

Urban space and, in particular, public spaces realize a variety of types of information transmission and are targets of many information providers. The process can be called a struggle for efficient information transfer and an incessant play for the attention of users – the city residents and visitors.

A short summary of the conclusions and results of the above work "On Orientation in The Space of The City" is given below.

According to the definition of orientation in the space of a city " ... orientation in the space of a city is the whole of man's psychophysical and spiritual abilities to define his place in the physical space of a city in the face of the meanings it carries. It should be treated as the basis for intentional movement, activeness and being in an urban space as well as the establishment of values and meanings.

Orientation in the space of a city: is fixed in space-time; binds and facilitates man's other relations in the environment; concerns what is included in space and perceptual but may be associated and identified with non-spatial meanings and values; is environmental (Gibson); concerns values and potential actions (Lewicki); is aware to various extents; in the broadest depiction, it remains under the influence of elements from the area of consciousness, including knowledge and abilities, and from beyond this area, including hidden memory, while a certain range of environmental monitoring is the constant, unconscious labour of an organism involving it at the level of reception as well as an initial selection and the valuation of stimuli; is related to various degrees of attention engagement in spatial orientation processes in relation to people's direct contacts or expression and concentration on non-spatial values and contacts (D. Broadbent, A.M. Treisman, U. Neisser and others) as well as man's emotional and cognitive disposition (K. Obuchowski); is connected with the

²⁴¹ The study was published in 2008 (Kantarek, 2008), and its abbreviated and revised English version was released in 2013.

characteristics of a manner of staying in a space (a kind of movement, objectives, the knowledge of the space); is based on the concrete, generalization or abstraction to various degrees (Obuchowski); is of local character; is of adjusting character, uses the most expressive elements, in a sense it accepts the state of things; so, it results in a kind of adjustment; is rooted in culture and uses the temporary knowledge of a city whose sources are diverse. ²⁴²

Typology	Examples Of Types
according to a place	place of residence, house, neighborhood places of work, education places of relaxation, recreation, destination places of motion characteristic places – Centre, regions, areas
according to motion in time	every day every several days, monthly yearly festive untypical
according to traffic – kinds of motions and vehicles	on foot by bike by car /driver, passenger/ by bus by tram
according to person – age, psychophysical condition, culture	child adult elderly person disabled person
according to person – relations to the city	inhabitant visitor – tourist, guest, employee
according to the degree of the cognition of space	

Figure 1. Situations related to orientation in the space of a city. A register of typologies (by the author) (Kantarek, 2013) p. 94

Attention should be drawn to several general determinants.

Firstly, orientation abilities are specific to a particular person – this includes individual perception abilities, cultural background, intrinsic values, interests, habits, age which make up a person's unique profile.

Secondly, orientation is dependent on the extent of the knowledge about the space.

Thirdly, orientation depends to a great extent on the manner in which one moves or stays in a particular space and hence on the kind of attention that is triggered (Fig. 1.)

Fourthly, it is a fixed ways in which a space is being used by a man, a group and a community.

A look at the space around man is one aspect of the issue. While asking about urban form we are concerned with another aspect – it is a reflection on the structure and dynamics of the changes in the anthropogenic environment.

There is a question about such a description of urban form and its elements that will help determine the best possible conditions of orientation in the space of a city.

²⁴² (Kantarek, 2008) p. 125, 126, (Kantarek, 2013) p. 91, 92.

This purpose is served by the orientating codes of urban form. There are four kinds of such codes²⁴³ (Figure 2.).

A *The own codes of a form*. U.Eco's definition of a code through an architectural sign can by analogy be extended to refer to an urban sign and subsequently a distinction can be made between inherent codes of urban form (semantic – denotation or connotation through form) and syntactic (the structure of the form). It is important to bear in mind that the codes operate on various scales and within various ranges – from the scale of a single object, interiors and their details, architectural forms, their complexes to any extended image of the whole of a city, region or the world. These are aesthetic codes.

B *Signalling codes*. These codes are based on the form but speak a different language. They are mainly signals defining the principles of movement around the city but also informing about the content of particular elements of the form – including designations and proper names of places. Their basis are written language or conventional signs (pictograms).

C *Mass transmission codes*. These codes in urban space use primarily pictorial and written language. Pictorial narration and linguistic message firmly embedded in culture create an attractive means of communication that captures attention. Basically, these are advertising messages – public sphere is involved in private messaging that works for the benefit of small groups of sponsors rather than the residents. The message, whose strengths lies in the application of repetitive elements of slogans and pictures, obscures the image of the city and makes identification impossible. It is a confusing element. Nowadays, the subject matter of the codes is extended from solely commercial to a wide range of political and cultural persuasion. More and more tools of transmission are being used – architecture and animated events in urban scenery become advertising banners.

It is worth noting that the message is external in relation to the space in which it operates. It uses the space and destroys it.

D *"Other codes incorporated in culture*, including information and events. All the other codes used by the city dwellers as the entire process of communication exist in the space of a city in an obvious way. They include both personal codes, related to the story of a life, based on subjective sensations and diversified, and many conventional codes built anew. Their coexistence and co-creation with an urban form is self-explanatory, unusually dynamic and elusive. They also include various manners of looking for a destination, e.g. asking the way or using GPS." ²⁴⁴

A diagnosis of urban space perception under contemporary conditions shows mass transmission and signalling codes to prevail. In the case of signalling codes this means that coding through form is too weak to satisfy the need for comfortable movement within the space or reflect the dynamics and complexity of connections. As for mass transmission codes, we are faced with unjustified interference with the urban public space of the content which has nothing to do with this space and affects recognizability of the site since it conveys a typified message.

Another question to be asked is what relations there should be between the elements that carry the particular codes in the city space to ensure optimum conditions for good orientation.

Orientation called *the orientation of balance*²⁴⁵ is in fact a postulate addressing urban form. To make possible the operation of other codes incorporated in culture (D), the own codes of a form (A) synthesize all the others. The composition of codes is based on the composition of the form of the city. (Table 1)

It is worth pointing out to what extent the above concept of orientation in the space of a city differs from K. Lynch's views on orientation in space.

Composition Of Codes		Composition Of An Urban Form In Accordance With The Requirements Of The Orientation Of Balance		

Figure 3. The composition of an urban form in accordance with the requirements of the orientation of balance (by the author) (Kantarek, 2008) p. 130, (Kantarek, 2013).

According to the definition given by Lynch in his book of 1953 (K. Lynch, *Notes on City Satisfactions* (1953), [in:] (Lynch, 1991, pp.135-153): orientation is "... the sense of clear relation of the observer with the city and its parts, and with the larger world around it. In the simplest sense it may be taken as knowing where one is at any time, and how to reach any other part." (p. 135). Although the concept is restricted to direct spatial relations and being aware of them, it is part of a more general definitione given above.

However, orientation is treated here as one of the seven areas of City Satisfactions(beside: Warmth and Attachment, Stimulus and Relaxation, Sensual Delight, Interest, Movement, Shopping and Entertainment). This means that it is in no way general in nature. It is one of the elements of satisfaction generated by a good form of a city; it does not determine other activities of a man or a community.²⁴⁶

K. Lynch regards orientation as way-finding, by which he means organization of a body monitoring the environment: "... it now seems unlikely that there is any mystic "instinct" of way-finding. Rather there is a consistent use and organization of definite sensory cues from the external environment. This organization is fundamental to the efficiency and to the very survival of free-moving life."²⁴⁷

And yet it is just the systems of orientation that form the basis for classifying the main elements of the image of the city. "The systems of orientation which have been used vary widely throughout the world, changing from culture to culture, and from landscape to landscape. (...) examples of many of them: the abstract and fixed directional systems, the moving systems, and those that are directed to the person, the home, or the sea. The world may be organized around a set of focal points, or be broken into named regions, or be linked by remembered routes. Varied as these methods are, and inexhaustible as seem to be the potential clues which a man may pick out to differentiate his world, they cast interesting side-lights on the means that we use today to locate ourselves in our own city world. For the most part these examples seem to echo, curiously enough, the formal types of image elements into which we can conveniently divide the city image: path, landmark, edge, node, and district."²⁴⁸

The question about Lynch's concept of orientation comes back while reading his "Good City Form" (Lynch, 1984). It seems to play a marginal part here, too.

Lynch presents the elements that constitute the basis for the spatial form of the city - Vitality, Sense, Fit, Access, Control and two complementary ones

– Efficiency and Justice. They should be regarded as requirements of a good urban environment.

The category defined as *Sense* (Lynch, 1984) pp. 131 – 150 includes: *identity, structure, congruence, transparency, legibility, unfoldingness and significance*.

Depending on the size of the urban system Lynch distinguishes two situations concerning orientation (within *formal structure*): "The next element of sense is formal *structure*, which at the scale of a small place is the sense of how parts are fit together, and in a large settlement is the sense of orientation: knowing where (or when) one is, which implies knowing how other places (or times) are connected to this place. " (Lynch, 1984) p. 134.

The concept of orientation is interpreted differently, depending on the extent of knowledge of the urban environment. Lynch points out that in a small and familiar place our awareness and attention are not engaged since our intuition and habits are sufficient to make use of the place.

In conclusion, the author's approach to orientation in city space presented in the paper differs from K.Lynch's theory. It seems rather to concern the level which Lynch defines as

²⁴⁶ The ways of such orientation thought of as self-location are defined by Lynch (pp. 135-137) as follows: directed lines, sequences, landmarks, spaces or areas, grid system, diffuse ["... compass orientation only, from various effects: streets which run in one or two general directions, though not on a grid (Bologna); large topographic features visible outside the city (Udine, Chicago); sunlight, etc." (p. 137)], topographic and symbolic.

²⁴⁷ (Lynch, 1960) p. 3

²⁴⁸ (Lynch, 1960) pp. 7, 8.

Sense (of settlement): "By the sense of settlement, I mean the clarity with which it can be perceived and identified, and the ease with which its elements can be linked with other events and places in a coherent mental representation of time and space and that representation can be connected with nonspatial concepts and values."²⁴⁹

The wide scope of the concept of orientation in the city space brings to mind the opinion of K.Obuchowski who wrote that " (...) we are taking into account all the levels of orientation – from an instinctive backward movement of a burnt hand to the definition of the meaning of one's own life."²⁵⁰

The presented concept of *The Orientation of Balance* based on the concept of *The Orientation in The Space of The City* as an explication of the relations between man's orientation abilities implemented in the city space makes many things clear but does not provide tools for action. Many urban practices nowadays ensure effective solutions to shape urban space properly in this respect²⁵¹ but many situations are still out of control.

The above remarks were made from the point of view of visual perception and in relation to the anthropogenic environment.

The reality is much richer than that. Perception comprises all the senses and the life of a city is the phenomenon of life of all of us and various personal relations on a myriad of levels.

The problems outlined in the book requires a broader perspective nowadays.²⁵²

First, it concerns looking at perception as a whole – through all the senses. Orientation is formed by various stimuli and received information and although the visual sphere prevails it is to a varying extent complemented or co-created by the other senses.

There remains the question about the ways of perception. Between the associationist and Gestalt perception theories there is a wealth of others (e.g. Reed's theory of pattern recognition, Gibson's theory of features, Marr's computational theory, Gibson's ecological theory) and each one highlights significant elements of the process.

Another important aspect of orientation is the manner in which the knowledge about the possibilities of moving around is gathered consciously and deliberately. This is not only investigation or asking the way but also using modern tools (GPS, the Internet).

Manipulating our attention is an increasingly important question these days. Not only do we live in the world of information overflow but also we are subjected to various scenarios that engage our attention. The scenarios employ more and more sophisticated measures and mainly concern advertising but can also be of a more general nature through promoting a particular lifestyle or simply a way of spending time.

²⁴⁹ (Lynch, 1984) p. 131.

²⁵⁰ (Obuchowski, 1967), p. 104

²⁵¹ In (Kantarek, 2008) pp. 132-154 examples of such solutions have been presented: comprehensive regulations, creation of new key sites for orientation and the redefining of the city space.

²⁵² In 2009 and 2011 surveys on orientation in the space of a city were carried out.

The surveys were carried out in Evora (Kantarek, 2009) (Kantarek, 2012) in 2009 among a group of students and tutors who had come there to attend a two-week workshop. The questionnaire was filled in on the arrival and its purpose was to show the knowledge of the space of the city among the people who had not been to Evora before. At the end of the stay, another questionnaire was filled in to show the knowledge of the city the respondents were already familiar with. An interesting finding was the fact that in the second survey, topographical features of the city were much more appreciated as *Elements of The Structure in Support of Orientation* (even though the respondents had learnt about the specific location of the historical city centre before); another point of interest was the appreciation of the venue (Giraldo Square – the city's main square) in the *Landmarks* category. Both elements were also appreciated in *The Most Important Elements of The Urban Structure* category. In 2011 first year students of the Faculty of Architecture were surveyed (Kantarek, 2011). In answer to the question: "What spaces do you associate with Krakow? Name several." they enumerated sites, regions and specific elements of landscape (edges, nodes, roads, dominants or accents did not count among significant answers) Significant elements listed in answer to the question: "Which elements help good orientation in the space of Stare Miasto" included nodes, accents squares and gates.

All the above questions are concerned with urban form. The reality of the three dimensions of space and time can synthesize other, more elusive dimensions of life.

Nowadays, defending the form of the city is essential. It is one way to defend the dimensions of the reality of our lives against the illusion that we can only live in virtual dimensions and that the fragmenting of the physical space and time is justified and possible. It is neither possible nor does it give grounds for seeking beyond them the earthly basis for the coherence of man as a person²⁵³ and hence of the life of a community.

We are concerned with a conflict, a clash or the situation that requires urban form to be defended.

The concept of codes composition (Fig. 3.) explains a lot – it says that composition in aesthetic terms is part of composition or harmony in a broader sense. Within the codes of the form we deal with a composition of volumes, requirements of open spaces where we move and a scope of meanings. The other codes transfer information (also through their form) which can help or hinder orientation in space.

Can we control the arrangement of space so as to facilitate orientation to the maximum extent? We seem to have reached the level of explaining and ordering notions rather than possessing pragmatic tools.

How can we define the mutual requirements of urban form and life activities going on in its dynamic and changeable contemporary reality to obtain such pragmatic tools? What tools should they be – of monitoring, control, prohibition or injunction?

This is, of course, the sphere of urban space management and there is a number of good practices in this respect. They should be promoted and inspire further regulations.

How shall we fight for the form of the city, its typological clarity and good orientation within it?

Since the city is, by definition, built on consensus, agreement – it is the agreement that is the means. This implies a regulation that is enforced as well as sensitivity to the dynamically changing needs of urban life and the stabilizing force of the built form of the city.

How can we build a kind of the *Map of Orientation in the space of the city* or a visual information system that would be based on the form of the city, on the message concerning the form? I do not mean another kind of coding through signalling codes – road signs or pictograms but a kind of formally legible composition of elements of the form that would facilitate orientation.

Some important areas are listed below: (i) Ordering the elements of the form by the orientation of balance requirements basically means eliminating the excess of signalling elements and mass communication elements. In some zones of the city there are regulations in force (an example is Polish legal formula of Culture Park); (ii) Rearranging the image of the city as viewed from the main access and transit roads (where signalling systems cannot be questioned). This system of roads forms the basic division of the city area into vast urban superblocks. The edges of these superblocks adjacent to the roads are filled in various ways but it is those urban superblocks and the sites from which new panoramic views or vistas can open that determine the orientating quality of communication sequences. It amounts to the requirement of legibility of particular city districts and regions; (iii) The concept of *the city of small towns* which has been popular for many years makes sense when primary residential environment is taken into consideration. Identification with the site on the basis of the space of the flat, house, neighbourhood or elementary educational or shopping facilities (local shop) is insufficient. A possibly complete hierarchy of connections with other districts (more distant neighbourhood, other functions) and the centre is necessary. The relationship between the centre and the outskirts is an important reference point; (iv) It is worth recalling the mechanisms defined by K. Lynch and referring to: (a) building the image of the city (developed along familiar lines of movement, construction of an enclosing outline, by a basic

²⁵³ In philosophical terms it is worth noting the contradiction inherent in our western civilization: individualism which is at its roots leads to the destabilizing of man's identity as a person and negating its individualization.

repeating pattern, as a set of familiar regions or developed from a familiar kernel²⁵⁴) as well as (b) related to stages of awareness, how parts are arranged in a structure (unrelated elements, flexible relations of parts to one element, flexible structure, related elements, rigid structure and multiplied connections²⁵⁵); (v) A particular role in the creation of the image of the city is played by powerful forms. Jacek Gyurkovich w (Gyurkovich, 1999) writes that a powerful form : „... focuses the observer's whole attention distracting it from other elements which participate in the creation of spaces and reducing their role to that of a background”²⁵⁶. The most important feature of the powerful form, beside attracting attention, is its emotional effect through distinctness (shaping, inner organization, scale).

The author treats the powerful form as an extension of J. Żórawski's concept of the strong form. In brief, J. Żórawski's theory²⁵⁷ is concerned with the perception and construction of the architectural form and is based on Gestalt psychology. Żórawski distinguishes two categories of form in relation to its environment: a strong form (when it dominates the surroundings) or a weak form (when it does not assume a dominant role). In terms of internal relations, he speaks of coherent forms (whose composition is fixed and unalterable) and free forms (where the relationship between the elements can change with no consequences for the whole) The concept of the powerful form is an extension of the strong form concept to include urban relations.

I imagine the *Map of Orientation in the space of a city* to be an individual document for each city that would oblige the city authorities to include its guidelines in the urban planning system and which would also form the basis for creating the image, or images of the city for the purpose of the Internet or advertising since orientation key points can differ in relation to a place or person. The top-down formula should be supplemented and enriched with local initiatives to create images of local communities. The map together with its documentation could be thought as an element of the *Open Book of Urban Form of The City*.

In the case of Krakow it would be advisable to include the *Map of Orientation in the space of the city of Krakow* in the *Study of the Conditions and Directions of the Spatial Management of Krakow* and to maintain its character of a dynamic monitoring-based document.

Urban form and social output

Romulo Krafta

E-mail: krafta@ufrgs.br.

Abstract. *Assuming that the ultimate purpose of the city is to provide support to human interaction and that opportunities to social interaction are unevenly distributed across the urban fabric, this paper reports some attempts to describe such a distribution, as well as to infer the role of urban form in it. In order to do that, it is proposed, firstly, a method to describe urban form from its smallest components up to the different urban fabric patches, to the entire spatial system, and second, a model to represent social interaction as a process associated to the urban morphology. Both the spatial description and the analytical model are discussed through the examination of some results, obtained through simulation.*

Key Words: urban morphology, spatial analysis, urban performance indicators

Introduction

Cities are places for social interaction (Batty, 2012, Bettencourt 2013, Jacobs, 1969). Social interaction occurs across cities in many different ways; it can vary according to group size, purpose, intensity, frequency, group composition and so on. It also can take place in different locations and settings, from the privacy of residential rooms to many collective gathering buildings to the open public space. All of them, regardless scale, type, location, etc., contribute to the social output of a city. In this sense, social output encompasses the so-called productive activities, as expected, as well as many others that invest in family, friendship, love, culture and civilization. All of them flourish in the city, some in concentrated ways, others scattered around, some daily, some occasionally, and depend upon the city to carry on.

The most recent attempt to capture such a process in a unified urban model and to describe it quantitatively has been by Bettencourt (2013); his model builds upon the notion that each individual has an actual interaction area, defined by the average distance he or she can cover in a day. The more mobile an individual is, the larger is its interaction, and consequently its social output. But area is not the only variable for interaction definition, as the presence of other people is essential, so Bettencourt considers an average density across the entire urban area, so that eventual more disperse areas will be compensated by others more dense. Mobility is, of course, defined by urban infrastructure, which puts urban actual form as crucial to social interaction and output.

Urban form is uneven and hierarchical, it is also occupied by so many different activities which contribute to its unevenness and hierarchy, some of those activities add to the basic urban form differentiation, some others can create their own differentiation. Moreover, mobility can vary widely within the urban fabric, all those evidences suggest that, despite the average described by Bettencourt's model being accurate, not only relevant differences in social interaction can be found, but also urban spaces can perform better or worse, according to their morphologic characteristics. The possibility of achieving a more morphologic based representation of social interaction distribution suggests that not only our understanding of the phenomenon would improve but our ability to act upon key components of city spatial structure, aiming at performance improvement, could be better.

Theory, model definition

Assuming that the urban fabric is an aggregate of many components, it is relevant to identify what they are, and how they are put together, from smallest urban bits. Figure 1 represents that, suggesting that the urban atom would have two types of matter particles – built forms BF and open public space PS, directly connected (A column in the figure), as well as other non-matter particles, called interaction-machines IP (B column). These are force-carrier particles of various kinds, associated to BFs, all sorts of institutions (families, shops, service providers, industries, ...), promoting specific interactions; associated to public spaces, other group of more ill-defined institutions, promoting less controlled interactions (C column).

In C, the figure suggests different types of social interactions, such as SI1, which could be strictly residential, SI3 & SI4 as two different types housed in a same built form, and SI2 as a more complex social interaction process involving the same people of SI1, 3 and 4, as well as other operators passing through the open public spaces. In this sense, the urban atom would entertain a same group of people (residents and eventual service users) in different types of social interactions, some more defined and controlled, indoors, and some less defined and controlled, outdoors. It becomes clear that some social interactions have trivial descriptions (residential, both isolated and grouped in condominiums), some are a matter of more careful consideration, as they do not have a previously known population (shops, offices, schools, hospitals), while public space is a mixture of local and passing by population.

Figure 1. An illustration of a urban atom: A: matter-particles built forms BF and open public space PS; B: interaction machines IP of different types, each one corresponding to an social institution; C: social interaction associated to each matter-particle (red cycle arrows) and accumulation in the public space (blue arrows).

Urban molecules of different sizes and shapes are easily derived from the atom, such as suggested in figure 2A. In the example, other particles are included, as open collective (although not public) spaces, such as front gardens, halls and other built spaces available to more than one interaction promoter IP. Molecules are, of course, joint together, forming the actual fabric, as in 2B, and the whole city.

Now, considering that every instance of spatial configuration is likely to house some kind of social interaction, the next step is to provide formal description to them. Social interaction is, of course, a function of the number of individuals present at a certain place, interaction with each other. The least a social interaction requires is two people, whereas social interaction could involve pairs, as well as any other amount of individuals. The larger the group, the higher the social interaction, in geometrical progression. Here social interaction will be taken by its root variable, population size P , relativized by a parameter K , which measures the specific social interaction's relevance (intensity, frequency, proportion to the whole social output). Social interaction is not cost-free, however, as individuals usually

travel, sometimes striving to get to distant places, to put themselves in the right place at the right time.

Figure 2. Aggregates of urban atoms; in A a urban ‘molecule’ made out of built forms BF (○○○○), collective open spaces (◇) and public open space (diamond); in B a second order aggregation of many interconnected molecules.

$$SI = f(P, K, (-C)) \quad (1)$$

Starting from the smallest particle of the urban atom, the residential BF’s social interaction population is the respective family, its relevance is probably high and the cost is nil, as the individuals involved in the actual social interaction are already there. In the equation 2, the expression $(P^I * C^i)$ implies that cost is per capita, meaning that in order to have interaction, C^i should be <1 . For residential BFs, C^i is zero. It is noteworthy that the opposite situation, in which cost is maximized, interaction could be null, or even negative. In this sense, interaction costs can prevent interaction, creating a sort of interaction passive. The possible values of K will be addressed later on.

$$SI(BF_{res}^i) = [P^I - (P^I * C^i)] * K^{resBF} \quad (2)$$

While residential BF’s social interaction is trivial, non-residential ones are more complex, due to the fact that their actual population is not declared, as in residences, but made out of individuals that travel from many other places, in order to interact at the given BF. One possible way to proceed with its calculation is to consider all interaction promoters, that is, service providers of one type competing for all potential consumers; in this situation, every individual qualified as potential consumer is likely to choose the place of interaction based on least distance, submitted to size and complexity of the offered interaction places. For every service type, the whole pool of potential consumers will be split up among all places of provision of that service, in different proportions, according to spatial distribution of population and size/complexity of places of provision. A measure of that configuration, called Convergence, is in Krafta (1996), and for the purpose of this work, could be taken as a measure of attractiveness of every non-residential BF, helping to define each BF potential population.

Despite being attracted to a specific IP, individual will necessarily be located at different distances from it, meaning that each individual will bear a cost to travel from home to the considered IP; such a cost can be appropriated through a travel time, taken as the sum of each shortest path’s spaces’ time, measured by the quickest mean of transport, at worst traffic situation. Normalized, so that the shortest travel time being zero (the case of an individual living in the same space as the IP) and the longest being one (the most faraway place of living) each individual’s actual travel time can be taken as its probability to carry out the travel&interaction; the chance of the individual living in the same space as the IP being one hundred per cent, whereas the most distant place being zero. In this sense, for each pair of spaces in which A is where the non-residential BF is located and B is where the residence of a potential consumer is located, the equation 2 applies, provided that population in B is resized by the convergence value of A, and the cost is the sum of travel times of all spaces

linking A to B through the shortest path. The overall social interaction in the considered non-residential BF will be the sum of all pairs A-n provided by the system. K is very high.

$$SI(BF_{IPn}^i) = \sum_i^j [(P^j * Conv_i) - (P^j * Conv_i * C^{ij})] * K^{IPn} \quad (3)$$

$$C^{ij} = \sum_j^p t^{jp} \quad (4)$$

In the equation 3, $Conv^{IPn}$ (convergence) varies between 0-1, the same occurring to C^i , so that the BF population will always be a part of total potential consumers of IPn , and the total cost will be at most equal to total population. It is notable that total population of all IPs is necessarily bigger than the total population of the city, as most individuals will be potential consumers of more than one service, so that the whole numbers need a further normalization based on the actual city population.

Collective spaces are usually placed in between BFs, the private realm, and the open public space. Social interaction in there is performed by the same people living or using the BFs attached to the referred CS. Reaching the CS from each BF involves a cost which is not measured only by the corresponding (usually very small) elapsed travel time, but also the overcoming of an institutional barrier, a locked door of sorts. K is low.

$$SI(CS_{IPn}^i) = \sum_i^j [P^j - (P^j * C^{ij})] * K^{IPn} \quad (5)$$

Open public spaces PS's social interaction has two basic components: locally it works just like a collective space, in which the population is the sum of all residents and other people attracted to it by the interaction machines. Added to it there is the moving population, that is, people passing through. Strong references on co-presence, that is, the relationship between local people and individuals traveling across city spaces are in Hillier and Hanson (1984). Estimation of flows, based on morphology is in Krafta (1994), a measure of centrality adapted from Freeman's betweenness centrality.

To each person present at a public space corresponds a travel cost. Residents will have to cross one or two institutional borders, service users are already there, their travel cost already accounted for. Following the method previously adopted, it can be assumed that travel cost will range between 0 and 1, meaning that people moving from the most faraway place in the system will have cost 1, which in practice make its interaction null. Social interaction in public spaces is, therefore, represented by the following equation 6.

$$SI(PS^i) = \in \left[[P(BF_{res}^i) - C_{res}] + [P(BF_{IPn}^i) - C_{IPn}] + [P(flow) - C_{flow}] \right] * K^{PS} \quad (6)$$

Territorial domain

The method explained above suggests that travel time, or cost, is always maxim at the most faraway location, which is obvious, and equals 1, meaning that the whole system's population is likely to be included in the global interaction process, in the sense that even the most remote residential location will have a travel cost < 1 and therefore an interaction value >1. More realistic and interesting is to consider that this condition does not always hold, and thresholds should be considered, such as Marchetti's (1994) invariant – half an hour, or the observed city's average travel time. With thresholds on, every BF holding a non-residential Interaction promoter IP will have a territorial domain, constituted by all reachable spaces

around it within the time limit. In this case, the normalized travel time value 1 won't be at the system's border, but on the threshold, and all spaces outside the territorial domain will be excluded from the considered BF interaction. This could be considered an interaction deficit, to be compared to the actual social interaction, resulting in an indicator of performance M^* .

Figure. 3. The notion of territorial domain in a one-dimensional city, defining the part of the system holding actual interaction in a particular space, as well as the part of the system excluded from it, therefore bearing a interaction deficit. The difference between positive interaction (yellow zone) and interaction potential unfulfilled (pink zone) is an indicator of performance M^* .

Establishing a threshold is not trivial, as both travel mode and urban form are involved. In general terms, urban form can be described through length, capacity and traffic density. The latter can easily be estimated by one of many accessibility measures available, working as a proxy for inverse speed and parking opportunity. However, such a description suits only one transportation mode, the private car, or public, surface, transport systems that use ordinary roads. For pedestrian travel mode, capacity is not relevant and speed is more uniform. Multi-modal travels are even more complex.

Two territorial domains seem to be relevant: the first related to purpose travels ending at the space being considered, and travels using that space as a link to elsewhere. For the latter, only pedestrian travel will count, as people passing through in cars or buses won't interact; for the former, all means should be considered. Territorial domain for pedestrians can be established once a distance/time limit is defined, using a simple accessibility algorithm. TD for people traveling to the considered space has two options: point-to-point car travel, and pedestrian-public transport-pedestrian one, provided that public transport runs on segregated lanes and are, therefore, free from the ordinary traffic congestion. In these cases, it will be necessary to proceed with time calculation, from length, capacity and traffic density, then to apply an algorithm which builds up a spanning tree from the space in question up to the threshold limit, calculating for every space visited, a population/cost factor.

Figure. 4. Spatial system (A) and graph representation of alternative space unit description: (B) space is described as street segments, in (C) corners and street ends.

Space description is relevant here, figure 4 shows an idealized spatial system (A) and two graph-representations, taking different space descriptions; the graph (B) considers space units as street segments, whereas (C) takes space units as corners and street ends. It is easy to realize that B representation is more intuitive and probably handier for population and activity appropriation; on the other hand, C is better for distance/time description. Figure 4

shows also a possible public transport route (red dots and lines), running on segregated lane, so that its speed is different from the ordinary traffic.

Up to this point, it has been described all interaction that a space unit can generate by itself, both from its own population and from the visitors it can attract. However, nearby space units, particularly those bearing commercial activities, are known to benefit from that propinquity, case in which people visiting one is encouraged to visit, and therefore, interact in the others as well. To this extent, space units can work together, as a macro molecule (MM). Territorial domain is clearly of pedestrians, spatially defined by adjacency and increasing cost varying with distance. Equation 7 captures this interaction

$$SI(MM_{IPn}^i) = \in [P(PS_{IPn}^j) - C_{ij}] + * K^{IPn} \quad (7)$$

Finally, the K parameter should be addressed; it has been valued as ‘high’, ‘low’, ‘very low’, etc., suggesting that each type of interaction adds differently to the overall social output of a city and therefore K can be estimated. Indeed, it is easily seen that some interactions involve large number of people, compared to others that take just a couple of it or little more, some are very frequent, compared to others that occurs rarely, some are very well programmed and controlled, compared to others that are next to random. All of them are socially required and productive, each one in its own way, probably even those which look destructive. One possible way forward is to consider the relative density of social interaction over the population involved. On the one hand there is the residential instance, in which few people develop and maintain constant interaction of each family member with every other; on the other hand there is the public space, where a large population develop a few, eventual interaction. In the former, it takes few people to get high level of interaction, in the latter it takes large population to get low lever of interaction.

Experimentation

In order to provide some evidences on the effectiveness of the proposed models, some controlled experiments were carried out. The city has been reduced to a one-dimensional string of sequentially connected cells, in which one half side is removed, as showed in figure 5. In this way, the cell on the far right is the centre. This simplified city is supposed to grow, from its most initial 2-cell embryo, up to 21 cells; in all its stages, the cells are filled with an Alonso style (1964) activity and population distribution, although at some point a secondary service centre is introduced, as explained later on. Total population in each stage is always 3X the number of residential cells.

Considering that built form constitution inside each cell is not specified (assumed as a single built form), residential interaction computation is trivial – equals the population of each cell, the same occurring with collective space’s interaction (non-existent), and public space (again, interaction there equals the residence’s one). A little more interesting is to observe how interaction in the centre occurs. Having no residential population of its own, the red cell attracts service users from all existing residential cells, who have to travel along the string. The simplified city implies that all cells are alike, meaning that infrastructure (roads) is equal; in this way, it is expected that traffic fluidity is maxim at the border and minimal at the centre (more congested). Traffic differential conditions at each cell have been taken as the inverse of accessibility, that is, at the centre, where accessibility is higher, traffic conditions is worse and vice versa. Length is equal for every cells, what makes the inverse of accessibility the only variable defining the travel cost from each residential cell to the CBD; this value has been initially normalized from zero (at the centre) up to one (at the border), meaning that all population is within the centre’s range, although the cost of each one’s actual interaction varies with distance. The computation of each residential cell’s contribution to population at the centre is then made as a probability of each resident to take the trip; the

ones living at the cell next to the centre is near 100%, the ones living at the most faraway is near 0%.

Table 1 shows some results from a full 21 cell system, considered in three different ways: *a*) having a evenly distributed population (3 residents in each cell) and no traffic fluidity influence (only plain distance), *b*) population distributed according to Alonso's general curve and no traffic fluidity influence, and *c*) same as *b*, with traffic effect taken into account. Situation *b* produces the highest interaction output, whereas situation *c* the lowest. This is quite interesting, for it, first, do suggest why Alonso's monocentric, non-linear population distribution's city is so right, as it seems to be the most efficient interaction generating spatial configuration. It also suggests that it only works when the undermining effects of congestion is minimized, otherwise it loses its density advantages. Table 1 also suggests that interaction taking place at the centre involves only a portion of the total population, varying from 45 to 75%. This however does not mean that 25 to 55% of it is excluded from it, but that not everybody will be interacting at a given time, although everyone will interact at some time.

Figure. 5. A One-dimensional half city made out of a string of 21 sequentially connected cells. It is supposed to grow from a 2-cells embryo up to 21 cells. Population distribution is as Alonso's general city form curve. Jobs and services are at the centre.

Table 1. Results for a 21 cell system, considered in three different situations: A) having a evenly distributed population and not suffering the effect of traffic congestion, B) having a non-linear distribution of population and not affected by traffic congestion, and C) same as *b*, with traffic effects.

	A	B	C
Total population	60	60	60
Total interaction	28,5	45	27
% pop/interact	47,5	75	45

As a second step, the one-dimensional city has been examined while it grows from the 2-cell seed. It has been done through the evolution of the M^* interaction performance indicator. M^* is defined as the difference between actual produced interaction at a nominated space and the interaction deficit at the same place. Interaction deficit is understood as the unperformed interaction. In this sequence of experiments, a threshold point has been adopted. Threshold point defines the territorial domain for the considered centre, it is assumed that, either for preference or travel restrictions, interaction will only be possible for people located within the territorial domain, leaving anybody outside it excluded from it. Inverse accessibility, as well as travel times are calculated so that cost at the threshold will be 1, resulting in a 0% interaction probability for those located just out of it. In the case of this experiment, threshold point was arbitrarily established, although in more realistic situations, it would replicate average travel times effectively experienced in a particular city, or the invariant travel time suggested by Marchetti.

Figure 6 displays evolution of actual interaction (blue), interaction deficit (green) and M^* (red) at the centre of a system growing from a 2-cell seed (position 2 in the X axe) up to 7 cells, considering Alonso population distribution, homogeneous infrastructure, and traffic effects represented by the inverse of accessibility. It is seen that M^* grows with actual

interaction growth from the beginning, but soon enough it falls down, crossing the X very quickly. This performance is directly related to provision of mobility infrastructure, in the sense that considering it evenly distributed, the system would have less than required road capacity in the central cells (and certainly more than required at the border). The green zone in the graph represents the interval in which CBD's interaction output is positive, red zone is where interaction deficit exceeds the actual one.

Figure 6. Performance indicators for the central space of a system growing from a 2-cell seed. M red curve suggests that social interaction at the centre is crucially dependent upon mobility infrastructure, as congestion effect at the most central cells cause the M indicator to fall sharply, becoming negative.

Figure 7 displays the evolution of the same system, in which a secondary service provision location is considered at the precise cell that causes the M indicator to become negative. The introduction of a new service location introduces a competition between the two centres for potential users, which is estimated by the measure of convergence. In this particular case, convergence of the principal service centre, which had been 1, falls to 0.76 (implying that the new one starts off with 0.24 convergence). It is seen that the introduction of this new service location not only stops the M fall, but makes it to perform positively again, near the level previously experienced (but still a bit lower). The graph captures this time the effect of spatial configuration on the social interaction, as M performance varies with changes in service locations and consequently with relative distances and mobility infrastructure provision.

Figure 7. Performance indicators for the central space of a system growing from a 2-cell seed, with two service centres. M red curve suggests that social interaction at the centre is fairly dependent upon spatial configuration, as accretion of a new service location makes it return to positive performance.

A third experiment with the same system has been carried out, this time simulating the effect of a transport system. To do this, in the last (eleventh one) step of simulation, it was assumed that, from the border, every other cell of the string were interconnected without the traffic effect (so those direct connections would be either underground or exclusive bus lanes). The display of indicators performances are in the figure 8. It is clearly noticeable the sharp upward tendency introduced in the M evolution by this, confirming the strict dependence of social interaction on mobility services. It is, then, expected that the introduction of transport in earlier stages of the system's growth would significantly change both the road infrastructure and spatial configuration's dependence of M , probably retarding and smoothing its decay.

Finally, figure 9 displays, on the left side, M for all system's cells, and on the right the overall M performance. On the left, red and purple thick lines catch the two service centres, whereas the others are residential. On the right side, blue line describes the overall system's M performance without transport, and the red one, a bit displaced, shows how the transport would make things change. The first graph displays two different types of social interaction, the economically productive ones, in spaces where interaction is more intense, and the family-related ones, in residential spaces. Other types have been omitted, in spite of being real and operational. The right-side graph, summing up all the system's social interaction, combines different kinds of interaction and, in this way, should take measures to weight adequately each one. This issue has not been approached here, so that the graph is just a demonstration, focused more on the comparison of performances with and without taking transport into consideration.

The simulation described above does not include interaction in the streets, in order to do that another set of calculations would be required, according the proposed model. Nevertheless, in this simple spatial configuration, it is quite predictable (increasing quantity of people in the streets from the border to the centre) and it would not change the tendencies previously described. Further levels of spatial aggregation are also left untouched; if unfolded, cell aggregation could reveal instances of social interaction potentially able to change the M overall profile, but still reinforcing the role of central spaces

Figure 8. Performance indicators for the central space of a system growing from a 2-cell seed, with two service centres and the introduction of a transport system in the last step of the simulation. M red curve suggests that social interaction at the centre is deeply dependent upon transportation, as accretion of a traffic-free transport line makes it shoot upwards.

Figure. 9. Left, M curves for all cells of the system, along evolution from 2 to 21 cells; right, M overall performance with and without transport provision.

Discussion

There are two aspects of urban dynamics addressed in this work, the intertwining relationship among spatial configuration, mobility infrastructure and transportation, and the performance of spaces and parts of the city in the social interaction promotion. The model, as well as the few experiments reported in this paper, has suggested a meaningful relationship among those elements of the city, being *urban form at the very heart of it*. Indeed, both spatial configuration and mobility infrastructure are the urban form's actual middle name, they are intrinsic to urban form; even transport systems are themselves conditioned by urban form. The reported simulation has taken urban form at its very basics, although it has allowed the necessary transparency, and so, allowed for a more controlled experimentation. It has provided early evidence on the pros and cons of the monocentric city and accumulated density, but most important, it has revealed an intricate interplay of scales within the urban system. From the most private bit of built form to the entire urban system, the city offers a variety of opportunities for social interaction, where the same individuals do perform different kinds of social interactions, within different groups. In this way, the model could have been revealing a sort of scaling functionality in the urban form, not only in its day-to-day operation but also in its long term fine tuning involving changes in location, linkage, and space provision.

The M indicator deserves a few words too; taking a relationship between effective social interaction and not fulfilled one, it could be indicating a sustainability dimension, in the sense that spaces displaying bad M scores would not be coping with its most fundamental purpose. More revealing, however, seems to be the global M, taken from the entire system, which more properly indicates the city's fulfilment of its fundamental endeavour. Nevertheless, the ability to determine each space's particular performance could be precious for planning and design purposes.

Abstract. Nowadays, a large number of Chinese towns and villages are undergoing an unprecedented transformation. The redevelopment normally favours a one-off urban design method and replaces the traditional fabrics with identical new faces. Although typo-morphological analysis is widely used to inform the characteristics of urban structures, not many studies focus on the role of environmental elements in pattern formation and infer the underlying forces of the structuring in coastal low-lying areas. In this paper, we first mapped 27 coastal villages and towns in Tianjin and extracted some key elements such as street networks, homesteads and three-section courtyard houses. We inferred the driving forces for the origins, expansions and transformations by using the historical and current satellite imagery along with water-related toponyms. We then classified the built environment of the villages into a three dimensional, typo-morphological matrix, and used 'complexity' to categorise the compositions formed by the elements across the three classes. Our approach, which is certainly not tied to the studies of villages, is obviously applicable to any other informal settlements in urban areas. Except for some impossible compositions in the matrix, the rest would offer a template for urban design and new forms generation.

Key Words: typo-morphology, mapping, toponymy, complexity, coastal lowland

Introduction

Although typo-morphological analysis is widely used to inform the characteristics of urban structures, not many studies focus on the role of environmental elements in low-lying coastal areas. Renowned for being lowland as the Netherlands is, the hydrological foundation for urbanism has not been rediscovered until recently (Hooimeijer et al., 2005; Hooimeijer and Geldof, 2007; Hooimeijer, 2011) and moreover, few studies have applied typo-morphology. Hooimeijer et al. commenced to investigate the transformation of Dutch cities with water and water infrastructures a decade ago, where the taxonomy of water towns has been established. Based on the water features and hydraulic infrastructures where a town is adjacent to, located in or situated on, the Dutch water towns are categorised into coastal towns, dune towns, sand ridge towns, river towns, dyke towns, dam towns, etc. According to the topography in which a town is located, more categories include polder towns, peat polder towns, geest towns, mound towns, brucht towns, etc. Hooimeijer summarized the structure characteristics or interrelations of the water, road networks and buildings for most water town types. The classification provides valuable insights for profiling the relationship between water features and urban forms. Nonetheless, citing an instance for each class is limited to performing typo-morphological analysis at the plot scale.

The use of typo-morphology has a long tradition in analysis of urban transformation. A few restrictions limit its application to the non-urban areas: firstly, the analysis is laborious and relatively subjective; secondly, the method is strongly context-dependent and hardly applicable to the homogenous fabrics of new developments or data sparse areas (e.g. informal developments); thirdly, the classic analysis focuses more on the built-form than environmental attributes. Apart from some continued applications to the analysis and evaluation of urban environments (Osmond, 2010; Wang, et al, 2013), there is an increasing interest in applying typo-morphology to urban design and planning (Gil, et al., 2012). Marshall and Gong (2009) developed a concept framework for the specification of a pattern

typology that could be used for either understanding an existing pattern or specifying a future one. A more fashionable method is to use pattern recognition and data mining to support information exploration, analysis and clustering. The basic idea of this method is to decompose the objects into geometric entities or morphological constitutions, which can then be defined by a set of measurable attributes. These geometries generate combinations, i.e. morphotypes, and produce accumulated attributes when combined, which can be classified into homogeneous groups by appropriate algorithms. Computer has advantages in dealing with laborious work to develop a consistent classification, distinguishing typological regularities and further, may create new geometric features to facilitate future design works (Serra, et al., 2012; Gil, et al., 2012; Chaszar, et al., 2013). In this paper, we will study the relationship between the hydro-driven forces and built-forms in the peri-urban and rural areas in Tianjin by using maps, remote sensing images, and water-related toponyms. Characterized by the one-storey, three-section courtyard houses built on homesteads, settlements in the non-urban areas are organised by the ad hoc 'self-regulations'. Homesteads behave as the Conzenian plots (Conzen, 1960) and act as an 'engine' of the urban structuring. Therefore, we will adopt Conzenian approach to define the corresponding complexes of plan elements.

Toponymic typologies of low-lying settlements

Ancient toponyms can contribute to studies on the origin and evolution of settlements, and water-related toponyms can help reveal settlement relationships to water during early phases of occupation. If the name of a settlement contains a water-related character, this settlement likely originated along or close to a water body. Nearly all of the major water-related characters can be identified in the names of over 5,000 currently used administrative division names in Tianjin. Such characters include "sea (hai, 海)" and "ocean (yang, 洋)", which represent water bodies that cover broad surfaces; "river (jiang, 江; he, 河)", "canal (qu, 渠)", "ditch (gou, 沟)" and "flow (liu, 流)", which represent linear water bodies; and "lake (hu, 湖; po, 泊)", "pond (tang, 塘)", "shallow lake (dian, 淀)" and "pool (ze, 泽; chi, 池)", which represent planar water-bodies. In addition to these easily recognisable water-related characters, geographical names in Tianjin also describe river terrain and topographies, providing geographic information on the origins of settlements in connection to water bodies. Many of these names do not possess water-related characters or may have unique meanings that differ from conventional understandings. According to studies by Zhou (2012) and Tan (2005), a geographical name containing a "circle (quan, 圈)" denotes an area that was once positioned along a meander bend, and a geographical name containing a "mouth or head (kou, 口; zui, 嘴; or tou, 头)" denotes an area that may have been located along a confluence or on the intersection of waterways. Certain geographical names may even provide information on the topographical characteristics of a settlement. For example, "heap (tuo, 坨)", "platform (tai, 台)" and "Gu (gu, 沽)" translate to "mound", "high ground" and "central highland in water", respectively. Village names containing the characters for "dyke (di, 堤)", "dam (ba, 坝)", etc. likely denote a settlement was built along a dyke or on a dam that would protect against flooding. Geographical names containing the characters for "islet (ting, 汀)", "beach (tan, 滩)" and "mattress (fa, 垡)" indicate areas located on flat, waterfront terrain, although there are slight differences between these terms. "Islet (ting, 汀)" refers to a small flat waterfront area, "beach (tan, 滩)" refers to a large depositional area that becomes exposed during the dry season, and "mattress (fa, 垡)" refers to land that is reclaimed by an army after the sedimentation of an older river. Geographical names containing the characters for "pit (wo, 窝)" and "depression (wa, 洼)" may refer to the villages that were once located in low-lying swampland. Water-related geographical names can thus provide additional information when topographic data are limited.

The identification of spatial features

We selected the sub-basin of Hai River as the study area. It locates in a coastal alluvial plain, surrounded by the Yongding New River, Waihuan River, Ziya River, Duliu River Diversion and the Bohai Sea (Figure 1a). It is characterised by dense water systems with interlaced rivers, the functions of which include flood discharge, transportation, drainage, sewerage and water supply for agricultural production.

Methods of visual comparison and element mapping using both historical and recent satellite images were applied to explore the influence of environments on village siting and expansion. Based on the principle of well-preserved village form, which refers to villages that do not combine with other villages and that retain the traditional courtyard living structure, 25 villages and two towns were selected as the objects of the study (Figure 1b). These objects cover the Xiqing, Jinnan and Binhai New Regions, which are located in the southern section of the study area and are especially concentrated in the southwest area of central Tianjin. According to the toponyms, nearly half of these villages may have a close relationship with water. For example, the character "tai, 台" in Xueweilai (薛卫台) Village and Chentaizi (陈台子) Village, the character "gu, 沽" in Gegu (葛沽) Town and Xinigu (西泥沽) Village and the character "tuo, 坨" in Xilantuo (西兰坨) Village all refer to waterfront highlands; the character "kou, 口" in Nanlibakou (南里八口) Village refers to an intersection of waterways; the character "wo, 窝" in Zhangjiawo (张家窝) Town refers to a depression; and the character "shuigao, 水高" in Shuigaozhuang (水高庄) Village directly refers a high water level. The majority of the other villages were named using a "surname + Zhuang" structure. The main sources of data used include a digital 1:10000 line topographic map, Google Earth satellite images (hereafter referred to as GE images) and historical satellite images collected through the U.S. CORONA program (hereafter referred to as CORONA images). The digital line topographic map was prepared in 2002. The GE images were captured from 2000 to 2014. Because many villages in the study area were demolished over the past five years and the quality of the 2004 GE images is relatively high, 2004 GE images serve as the primary source of element extraction. The CORONA images primarily cover the left oblique section of the study area and provide relative high quality data for 1967 and 1970. Although they show the approximate boundaries of built areas and farmland textures, it was in some cases difficult to distinguish linear water bodies from roads and ponds from fields/grass/wasteland.

Mapping of the first decade of 21 century village morphology was conducted for all of the research objects. Using water bodies and farmland as the geographical environmental factors and streets and homesteads as the interactive artificial construction factors, elements related to village morphology, including natural and artificial water bodies, street networks and homesteads, were extracted. Most natural water bodies (rivers, streams, depressions, ponds, etc.) were extracted from the 1:10000 line topographic map, which was compared to the GE images. When necessary, minor manual adjustments to the comparative results were carried out. The extraction process for the street network was more complex than that of the water bodies, and we extracted streets of three levels, including crossing roads, main streets and lanes. It is inappropriate to classify street networks solely according to absolute road width. Thus, using the GE images as the control, the streets were classified according to their functions and relative widths in addition to other characteristics. A crossing road generally refers a road that crosses the core area of a village and that connects to other regions; the main street is a street that encloses a block following a homogeneous pattern; and a lane is a path that connects individual homesteads. Lanes that have developed spontaneously tend to have a width of only two to three meters and are thus not easily recognisable through the GE images. However, after removing all homesteads from a block, the remaining space is primarily composed of paths to homesteads. These particular street networks were thus not directly extracted in this study. Homestead borders and internal courtyards were extracted

through visual judgments of the GE images as well as through hand-drawing with judgment bases comprising traditional local residential courtyard formats, shading from the boundary walls, the ages of adjacent buildings and so on. Meanwhile, public buildings in the village were extracted.

Figure 1. Location maps: a) Hai river sub-basin in which the villages and towns are located; b) Locations of 25 villages and two towns.

Limited by the photographic range, the CORONA images cover only fourteen out of the 27 research objects. They were used to infer the siting causes and expansion driving forces of village primarily through visual comparisons with GE images.

Inferring the location and structural evolution

We used Corona satellite imagery to infer the siting history of the villages. According to the type of the water body to which a village is adjacent, we divided the villages into five main categories. The first category is composed of villages that are located adjacent to a major water course. Dangcheng Village (当城村) and Shuigaozhuang Village (水高庄村) are located outside the right bank of the Ziya River; Xiniantuo Village (西碾坨嘴村) is located across the Nanyun River and was constructed along the sinuous embankment. Rivers close to Dangcheng Village and Xiniantuo Village follow a north-south orientation, and both of the villages exhibit comb-like structures, with the comb teeth perpendicular to the river. Rivers adjacent to Shuigaozhuang Village follow a southwest-northeast orientation, and this village has a comb-like structure lying perpendicular to the river that follows the northern section of the river for approximately 80 meters. A large tract of land southward was positioned at a 60° angle to the river, with buildings distributed in the south-easterly direction.

The second category includes villages that are located at the junction of a tributary and a larger water course. Beiyang Village (北洋村) is located approximately 1,000 meters from

the point where Weijin River flows into Hai River. Xiniigu Village (西泥沽村) is located along the eastern side of the old channel of the Hai River, which is located 500 meters south of the junction of the old Hai River and the current Hai River. The western boundary of the village is positioned approximately 100 meters away from the old Hai River.

The third category accounts for villages that are located at the intersection of several small waterways. As it was not easy to identify small streams and roads from the CORONA images, we primarily made judgements based on the identification of sinuous morphologies. We therefore speculate that the Nanlibakou Village was once located in a floodplain at the intersection of multiple streams.

The fourth category encompasses villages that are located close to a constructed waterway. The constructed waterway identification from the CORONA images requires considerations of river names (Irrigation River, Diversion River, Drainage channel, etc.), shapes (straight) and related historical information. It is evident that few of the villages studied are located close to a constructed waterway, and the dominant orientation of the villages is north-south with no perpendicular or parallel relationship to constructed waterways.

The fifth category includes villages located close to a pond. It was observed that most villages that are not adjacent to a natural river are positioned next to a pond, and some villages are positioned close to multiple ponds, such as Xiaobianzhuang Village (小卞庄村), Gaojia Village (高家村), Xiaodianzi Village (小甸子村), Shizhuangzi Village (石庄子村), Yuejiakai Village (岳家开村) and Zhoulizhuang Village (周李庄村). For example, the area of Wangzhuangzi Village (王庄子村) is divided into two sections positioned at a distance of approximately 150 meters apart, and each section is located adjacent to a pond. These ponds are typically fairly large, covering up to several thousand square meters. Certain ponds exhibit irregular morphologies, while others show regular morphologies with border ridges.

Due to the relationships of village forms to water bodies in 1967 and 1970, the coastal area in Tianjin is a low-lying area, and the selection of locations for settlement was affected by comprehensive considerations of many factors, including water usage, flood avoidance and proximity to water. Proximity to an open water body represents the most important driving force. As long as flooding can be avoided, people prefer to live as close to water body as possible. Accordingly, the villages were located along river embankments. In cases where a river was not especially wide, villages tended to develop along both sides of the river. When a nearby river was not readily accessible, villages primarily developed around ponds. Topography is also an essential factor for siting a settlement. Several villages are located on large tracts of farmland far from water and roads, and some settlements separated into two parts over the course of development. We speculate that the relatively high terrain on which these villages were established may have been selected to avoid flooding. Settlement location selection was not affected by constructed waterways because they were just excavated in recent decades. Moreover, the names of Chentaizi Village, Shuigaozhuang Village, Xinigu Village and Nanlibakou Village reflect consistencies between village names and their geographical features. While the character "pit (wo, 窝)" in Zhangjiawo Town (张家窝镇) implies "low-lying", this could not be verified due to missing elevation data in the existing maps (Figure 2).

Following 30 years of development, the settlement area of Dangcheng Village and Shuigaozhuang Village along the Ziya River not only expanded to the entire area surrounding the river but also spread across the road (the original outer boundary) toward outside embankment. Beiyang Village and Xiniantuozui Village, which originally crossed a river, became completely fused. Ponds that were originally located along the edges of the settlements were later located within villages, and some ponds were even located at the centres of villages. Except for the pond adjacent to Xiniantuozui Village, which decreased slightly in area, the area of the other ponds did not change significantly, and the pond boundaries were smoothed. Large ponds were typically found along the edges of expanded villages. In fact, the southern boundary of Shizhuangzi Village (石庄子村) fully invaded adjacent ponds, resulting in an interwoven pattern of built area and water body. If constraints

had not limited the pattern of develop, the village would have expanded in a fan shape facing south. A village would expand southeast if a crossing traffic lies to the east of the village. Likewise, it would expand southwest if a crossing traffic lies to the west of it. Only when space for expansion southward is limited will the village grow northward. During the development stage of a village, the orientation of the homestead will be adjusted according to the farmland orientation. Fine, cultivated traces of farmland ("canvas grid") limited the growth of the street network and homestead. The old farm road became the basis of the street network. The developed village boundaries are largely composed of peripheral roads, drainage ditches and farm ridges that create neat borders. When the area of a farmland block was small with changes in texture orientation, the local border of the village was neat while the overall outline developed into a complex polygonal shape (Beiyang Village).

In summary, we conclude that the environmental factors that drive a village to expand include closeness to water, storm drainage, crossing road and living habits. The initial requirements of water access and flood avoidance at the time of village siting gradually lessened with the influence of recently available household tap water and with the construction of Duliu River Diversion. We inferred that the preservation of ponds addressed drainage needs, and more importantly, lacking of soil.

We then compared the 27 village street network structures obtained through mapping (Figure 3). Of these 27 villages, 26 possess a grid street network structure that is longer along the north-south orientation and shorter along the east-west orientation. Road networks close to a river typically exhibited an orientation perpendicular to the river as well as another orientation parallel to the river, thereby causing deformation based on the river curve. Along the peripheries of large ponds, road networks form loop or alternative routes and may be directly interrupted by the presence of a small pond. Other village road networks adapt to farmland textures based on ridge orientations. Although most of the street networks originate from a regular grid, the internal texture is no longer a grid structure if seen from a scale no larger than a block. We therefore further investigate the characteristics of village textures at a plot scale.

Classifying the interactively computational settlements

Using Conzenian approach, the planes of the villages and towns contain three distinct complexes of plan elements: streets/street-blocks, plots (homesteads) and their aggregation in street-blocks, and buildings within those homesteads. Texture characteristics are difficult to describe. From the perspective of physics, Salingaros drew from theories of computational complexity and classified urban substantial morphologies into four categories: interactive computation, non-interactive computation, random and non-computational. Among these classifications, non-interactive computation is primarily conducted through a planning approach that employs strong compositions, and the random category refers to the so called parametric design in recent years. These two categories are not common in villages. The texture of the villages in this study includes two extreme cases of interactive computation and non-computational forms, and the former is dominant. However, the degrees of "interaction" were different for the two extreme forms.

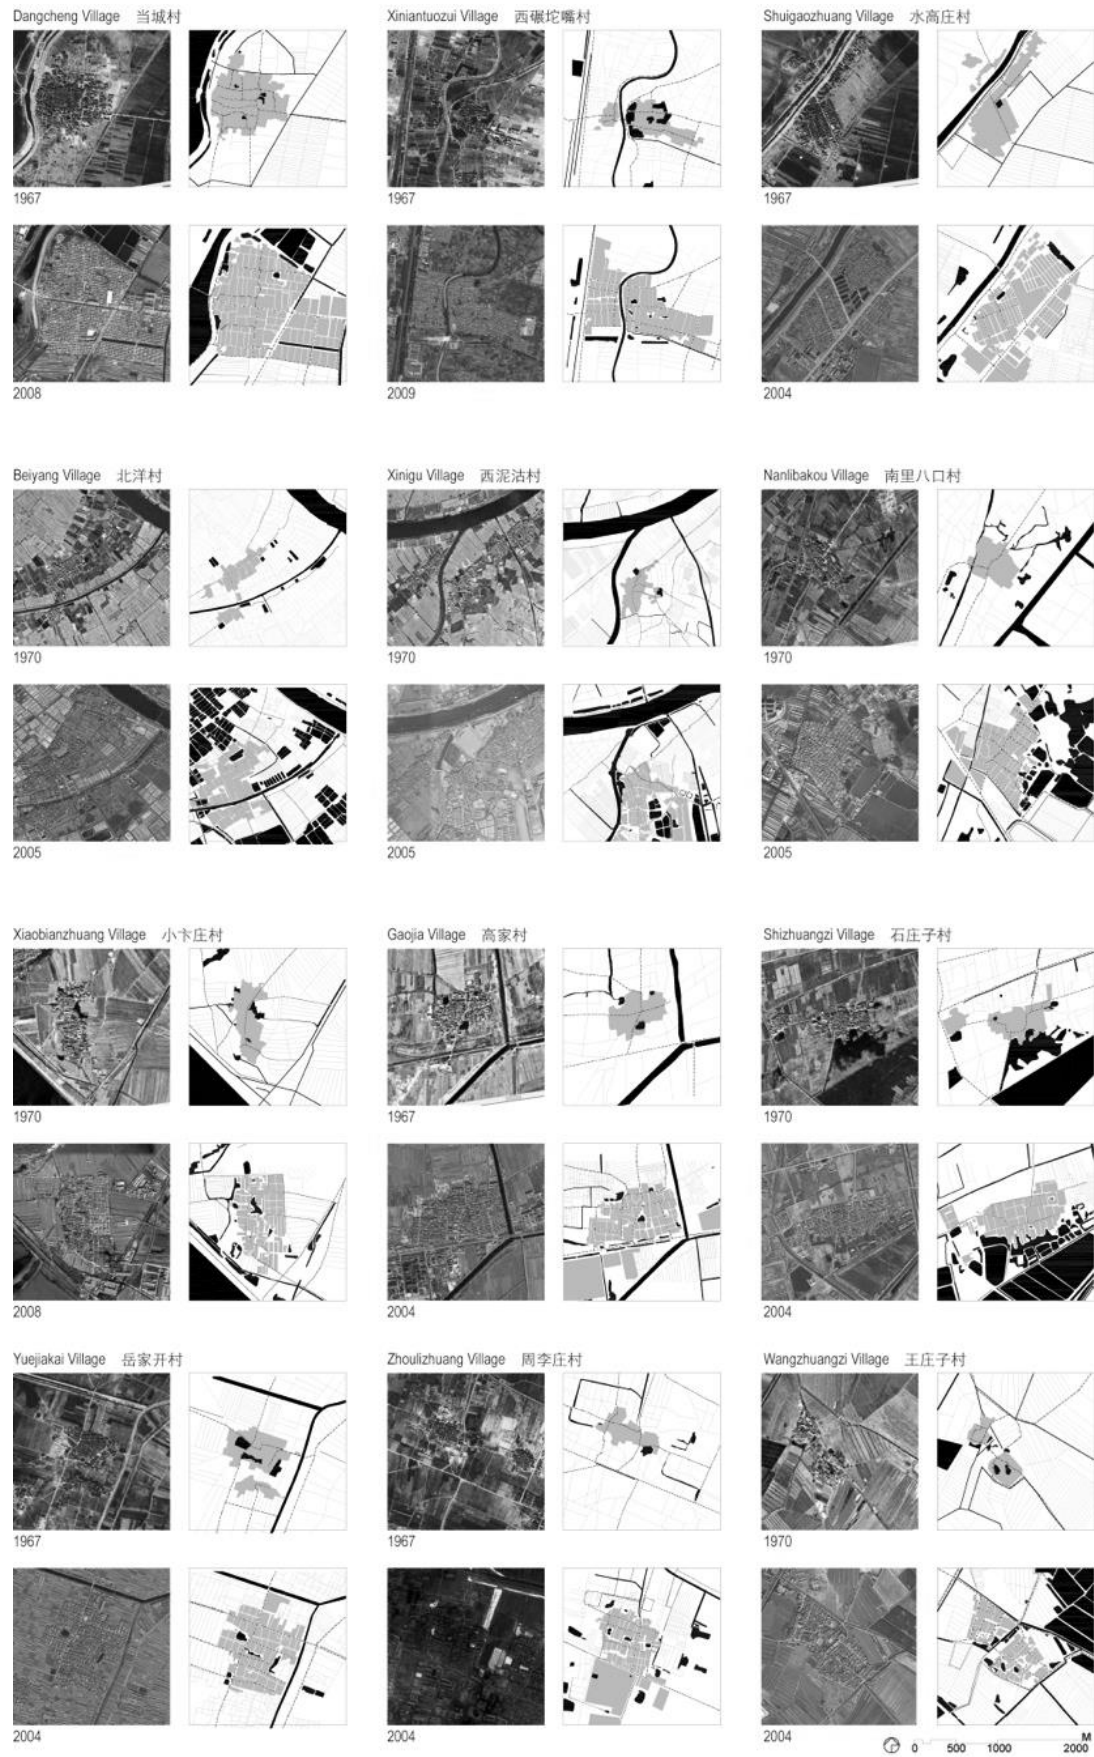

Figure 2. Comparisons between the historical and recent forms of villages.

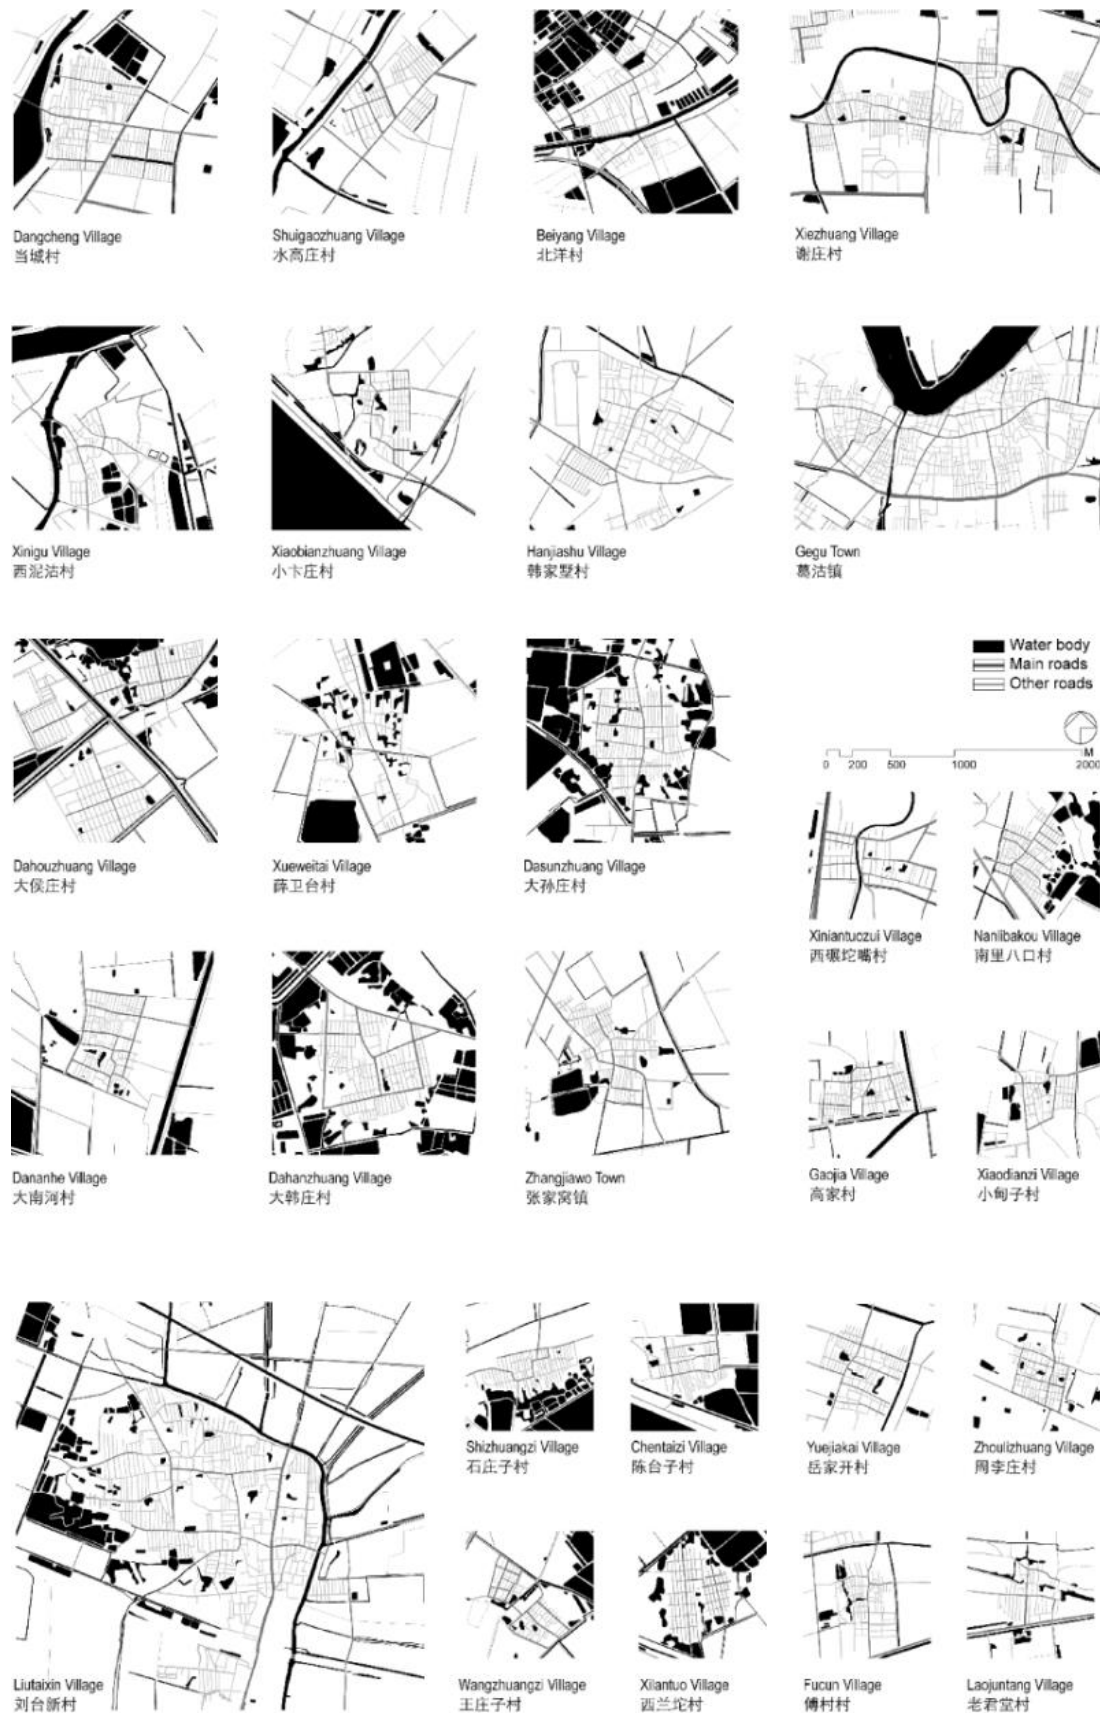

Figure 3. The relationship between the street networks and water systems.

Since Salingaros did not subdivide the class of "interactive computational" form, we devised a method that facilitates the sub-classification and cross combinations of the three plan elements. The elements of each level were expressed as a polygon or combination of polygons of different forms, and the orientation and length variations (abbreviated *Ov* and *Lv*, respectively) of the polygon edges were used together to evaluate the richness of information for this element. A value of *Ov1Lv1* indicates that changes in orientation and length are small; *Ov2Lv2* indicates that changes in orientation and length are large; and *Ov1Lv2* and *Ov2Lv1* indicate that changes in orientation and length are small in one instance and large in the other. Because local resident house orientation requirements are relatively homogeneous (south-facing), the *Ov1Lv2* category represents more self-selection. *Ov1Lv1*, *Ov2Lv1*, *Ov1Lv2* and *Ov2Lv2* show the information richness in the order of simplest to most complex. For the sake of simplicity, these are expressed with the values 1, 2, 3 and 4, respectively. For example, *S1* may represent an orthogonal street system that is nearly equal in width and interval. Next, an inter-level crossing was executed for each element.

The method involves first defining combinations of streets and homesteads in various classifications (Figure 4a) and then cross-combining these combinations with each category after the screening of results (Figure 4b). Three major screening criteria were applied: 1) the information richness for high-level elements should be lower than that of low-level elements (e.g., the information richness of streets should be lower than that of homesteads so that the *S2H1*, *S3H1*, *S3H2*, *S4H1*, *S4H2* and *S4H3* combinations may be excluded); 2) the information richness of orientations should be consistent with each other when plan elements at different levels are cross combined. Hence, the compositions formed by elements from the odd-number classes with elements from even-number classes, or vice versa, e.g. *S1H2*, *S3H4*, *S1H1B2*, *S4H4B4*, etc., were deleted; 3) since buildings in villages are all self-built, the combinations involving *B1* and *B2* were also excluded. After verifying the above principles through real village comparisons, we obtained the 'six basic compositions' in the order of simplest to most complex: *S1H1B3*, *S2H2B4*, *S1H3B3*, *S2H4B4*, *S3H3B3* and *S4H4B4* (Figure 6). For simplicity, we used *I*, *II*...*VI*, to denote the above six basic compositions. The six settlements of Dangcheng Village, Shuigaozhuang Village, Xinigu Village, Xiaobianzhuang Village, Xiaodianzi Village, and Yuejiakai Village were selected for a case study to further investigate internal temporal and spatial morphology changes in villages at the scale of the plot.

Following the above complexity classification model, the villages were classified into varying levels of complexity for the preparation of a grey tone map. Town and village construction boundaries over the two different periods were then superimposed onto the grey tone map. We also calculated the weighted complexity of the two periods (Figure 6). We found that all six villages showed a trend of a gradual decrease in morphological complexity from the village centre to the perimeter, or from one side to another. The morphological complexity level showed a specific correlation with the phase of the village construction. The settlement area morphological complexity levels were dominated by V and VI before 1970 and by I and II at the first decade of 21 century. Thus, rather than overall reconstruction, the growth of these six villages was primarily driven by external expansion. Borders of high complexity in the village centre experience more disruption than the less complex outer boundaries of the lower peripheral region. Public constructions are primarily located in the boundary areas between two levels of complexity, indicating that public buildings were constructed during periods of village expansion.

b . Combinations of streets, homesteads and buildings

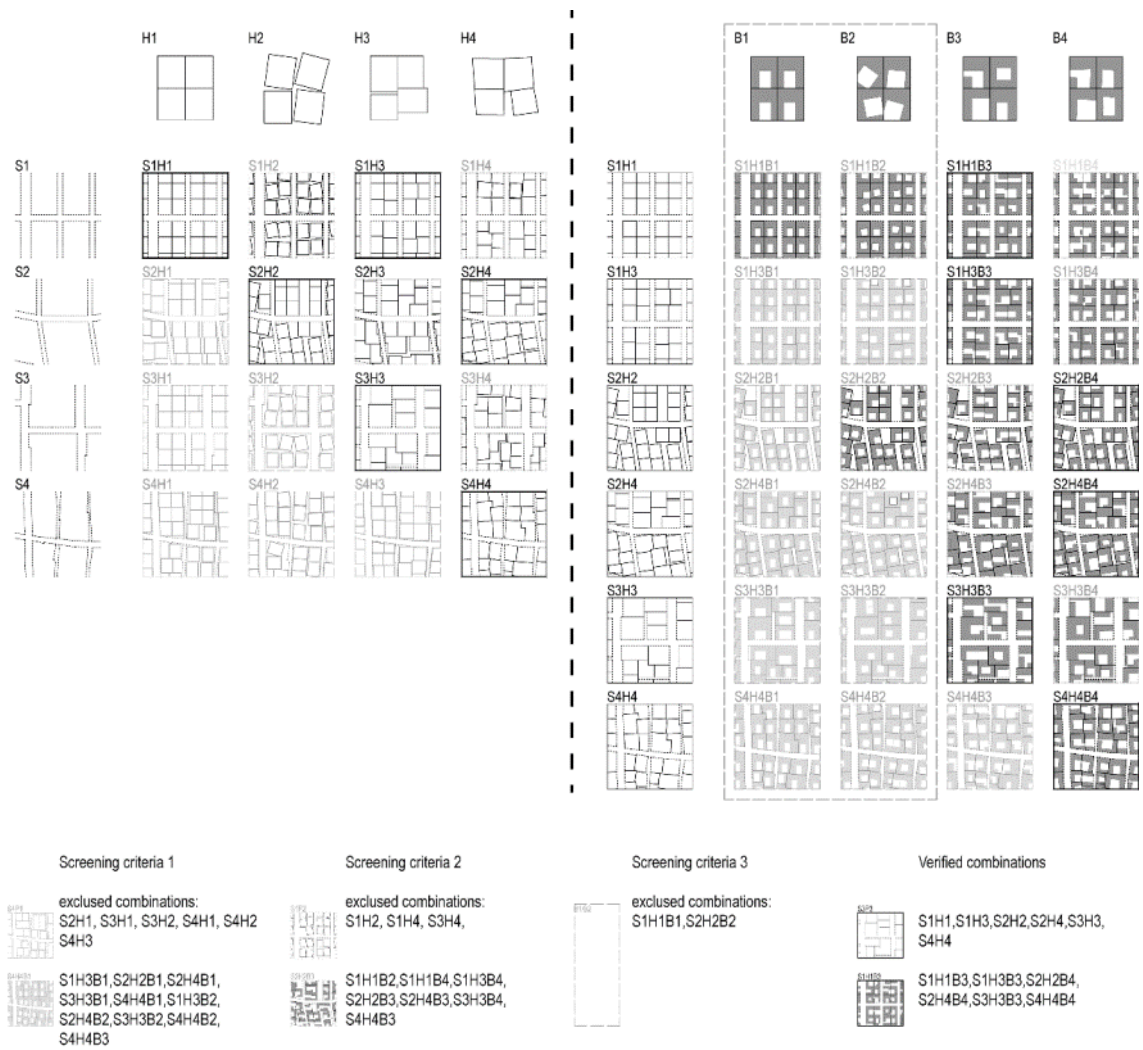

Figure 4. Selected typo-morphological matrix showing the inter-level combinations of the three elements: streets, homesteads and buildings.

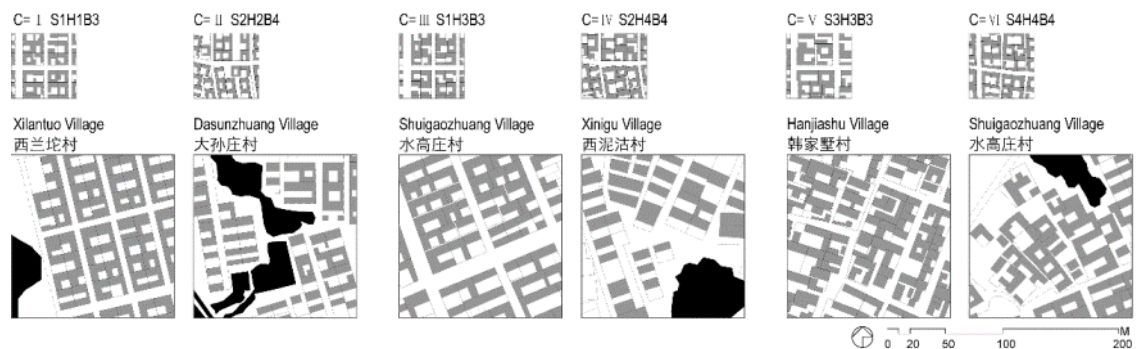

Figure 5. Selected six combinations shown in the village segments.

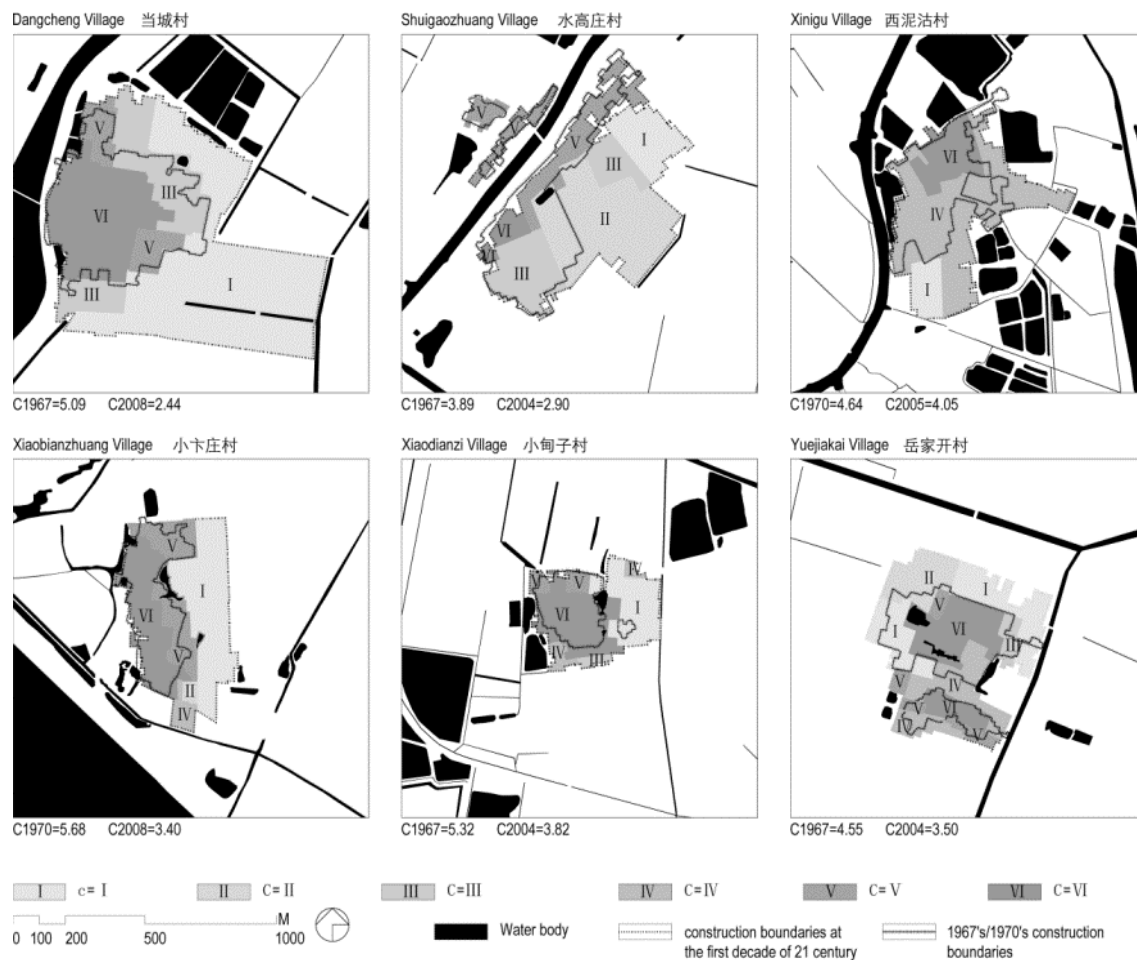

Figure 6. Degree of complexity of the tempo-spatial morphology of six villages.

Inference of homestead-scale interplays

We also examined interactive patterns between homesteads, streets and water bodies. The homestead is the smallest unit of the village environment. Deformations of the road network will thus be affected by homestead aggregation. From 1967 to 2004, homesteads located along village boundaries gradually compacted from loose formations, and the homesteads that were built later on have not always been located adjacent to existing homesteads. With the splitting of households and the arrival of migrant populations, open spaces within villages were gradually occupied. New homesteads were constructed based on existing homesteads and roads, and road borders were gradually defined by homesteads positioned along both road sides.

Homesteads exert the greatest impact on road network morphologies with respect to entrances and angular distributions. The courtyard style house possesses only three entrances along the east, south and west walls. An east-west lane can thus provide the entrance to the north side of a homestead, while a north-south lane road can provide east and west entrances to a homestead. The road network structure of the villages thus follows a grid morphology with lanes of a north-south orientation and with main streets following an east-west orientation. In a strict regular grid, the space between two lanes comprises the width of two homesteads. Homesteads are thus not only affected by the overall pattern of the road network

but are also affected by street linearity. The shape of a single homestead forms a roughly regular rectangle with at least one side of the building lying perpendicular to a water body or road. In spontaneous morphologies, when the border of a water body in a village is irregular, the orientation of the homesteads adjacent to this water body is adjusted accordingly, forming a grid with deformations that are approximately parallel or perpendicular to the water body. We observed a combination of homestead areas following differing orientations, suggesting that these homestead had been planned as integrated zones.

In addition to being affected through a bottom-up process by homesteads, the intercepted texture findings of this study show that road networks may also be destroyed through top-down processes of macro-control. The satellite image of Hanjiashu Village (韩家墅村) shows an oblique crossing road lined with buildings along both sides, with homesteads along the road boundary that do not respond to the road orientation, denoting the occurrence of splicing (Figure 7). This road was thus developed after the village texture had already been established.

Figure 7. An oblique street running through the Hanjiashu.

Conclusions and discussions

Inspired by Conzenian approach to interpreting urban forms with three classes of elements and Salingaros' thoughts on the urban forms as computational complexity, we classified and mapped the built environment of the low-lying villages into a three dimensional, typomorphological matrix. Here, the hierarchical method of traditional typology is challenged by the seemingly homogenous villages where elements at different classes are frequently twisted. We used 'complexity' to categorise the compositions formed by the elements across the three classes, and 'information richness' to classify the properties of elements within the same class. When completely listed, we would gain 64 compositions and form a total set of the degrees of 'complexity'. For the sake of simplicity, we picked out six possibilities out of the 64 compositions and assured that no compositions from our villages fell out of the scope. Our approach, which is certainly not tied to the studies of villages, is obviously applicable to any other informal settlements in urban areas. Except for some impossible compositions in the matrix, the rest could offer a template for urban design and urban form generation. Our method, however, stays in qualitative analysis, which indeed relies on an analyser's intuitiveness.

Although not widely verified, our method lends help to understand the formation of low-lying settlements in coastal Tianjin. The small sample analysis suggested that the older the part of a village was the higher degree of the complexity it exhibited. The only exception, Xinigu Village, which demonstrates an equally high complexity throughout the history, is because the village has been surrounded with abundant water features. The high complexity arises when frequent interactions between the plots and water features occur. Similar to the research into the history of Dutch water cities, many low-lying settlements originate from mounds, opt to live with waters, and develop with water infrastructures (Hooimeijer *et al.*, 2005; Hooimeijer and Geldof, 2007; Hooimeijer, 2011). Accessibility to water supply and avoidance of flood hazards would be the primary factors for siting a village, as evidenced by the toponyms in Tianjin. Villages that abut river levees would remain somewhat orthogonal to the river reaches when expanding, and the expansion of others would normally depend on living conditions, construction cost and industrial development, whereas the need of water is substantially decreased. We therefore concluded that before the systematic water management significantly loosened the tie between the urban form and surrounding water bodies, the water-related settlements in Tianjin were logically shaped by, and thrived with water systems. Insofar as structural measures for the systematic flood control has established and consolidated in the Hai river sub-basin, the development of villages located in the sub-basin barely illustrates the responsiveness to water features.

Industrial-housing ensembles at Lisbon: morphology and spacialization

Gonçalo Antunes, José Lúcio, Nuno Pires Soares, Rui Pedro Julião

e-GEO, Research Centre for Geography and Regional Planning, Faculdade de Ciências Sociais e Humanas, Universidade Nova de Lisboa, Avenida de Berna, 26-C, 1069-061, Lisboa, Portugal. E-mail: goncalo.antunes@fcsh.unl.pt, jmrl@fcsh.unl.pt, nhpsouares@fcsh.unl.pt, rpj@fcsh.unl.pt

Abstract. *This study aims to analyze the housing solutions implemented during the 19th century in Lisbon, focusing in particular on pátios and vilas operárias. Main objectives: i) classify, analyze and describe the urban morphology of pátios and vilas operárias; ii) understand the relationship between urban morphology and toponymy. Clarify the terms "pátio", "vila", "rua", "travessa" and "beco"; iii) analyze which steps have to be taken in order to conserve and adapt this complex heritage; iv) analyze the spatial distribution and points density of pátios and vilas operárias by using the potentialities of Geographic Information Systems, as well as analyze and describe its spatial matrix;*

Key Words: *Vilas operárias, pátios, Lisboa, industrial-housing ensembles, industrialization.*

Introduction

The population lodging is recognized as one of the major urban issues of the last two centuries. Recently the urban population equaled the rural population.

The urban demographic explosion was experienced in several large cities. In Portugal, the population explosion in large cities occurred after 1850 and also during this period started its first industrial developments.

In Lisbon, in the second half of the 19th century took place the first great population impulse, with the arrival of rural population (Brito, 1976). The city newcomers passed serious difficulties to get decent homes. The poor population lived commonly in housing ensembles analyzed in this work: *pátios* and *vilas operárias*.

Methodology

We proceeded to the information collection and georeferencing. In this sense, were collected and georeferenced 562 *pátios* and 364 *vilas operárias* (total: 926 elements), using the following methodology:

- i) information collection: books, articles, annuals, geographic information and fieldwork;
- ii) georeferencing and data processing: list of *pátios* and *vilas operárias* (name, localization, date, parish);
- iii) data validation with historical cartography, particularly: Filipe Folque 1856/57; Silva Pinto 1911; Lisbon Municipality 1950;
- iv) map creation: spatial distribution; mean center; standard distance; directional distance, and; spatial density (Kernel density estimation).

The spatial analysis makes use of the following measurement forms: mean center, standard distance, ellipse distance.

The density maps are exploratory analysis that aims to estimate the intensity of phenomenon occurrence. Thus, it was possible to generate a grid whose values reflected the

intensity of the phenomenon per unit area. This made possible to calculate the value of *pátios* and *vilas operárias* per km².

To the density maps was used the Kernel density estimation method. For the density maps production was used: *grid* (using *Kernel density*); cell dimension: 10 meters; search radius: 1 000 meters.

Results

19th century housing crisis

In Lisbon, during the 19th century the precariousness housing scenario had the condescension of the central and local government. Public authorities considered themselves unable to respond to such challenge. During this period it was believed that the housing market would eventually meet the housing needs of the population (Batista, 1999).

In Lisbon, the first answer to demographic explosion was based in buildings over-occupancy. The city newcomers were forced to live in poor conditions, settling in substandard dwellings, unoccupied houses, ruined palaces, convents, small rooms and basements (Pereira, 1994; Teixeira, 1992; Almeida, 1993).

Thus, the initial response to population growth was the occupation of derelict buildings. In result, the population density increased within the historical perimeter of the city.

Lisbon grew "inwards": pátios

After the buildings over-occupancy, real estate entrepreneurs realized that they could use the backyard to increase profits. Accordingly, *pátios* emerged as a natural conjectural evolution.

Thus, entrepreneurs with limited economic capacities began to build *pátios*. The *pátios* construction meant a small, profitable and secure investment. (Teixeira, 1992).

Ethnographer José Leite de Vasconcelos (1959) defined *pátios* as courtyards with single-family homes around. In the center *pátios* has a space open to the sky, surrounded by small precarious homes. *Pátios* can be thought as semi-spontaneous forms of accommodation that occupy the consolidated urban space. Without planning and as a fallback solution, these habitation ensembles seek to maximize land use (Salgueiro, 1992).

Pátios were small and informal unhealthy houses ensembles, where welfare was not a concern. Stands out the poor habitation conditions, where prevailed construction problems that did not guaranteed minimum living conditions. Bad sanitary conditions potentiate pathogenic problems, increasing hazards to the whole city.

Pátios: spatial analysis

We proceeded to collection and georeferencing of *vilas operárias* built in Lisbon. We identified 562 elements. From the information contained in Figure 1, 2 and 3 we highlight the following results:

- i) in the northwest boundary of Lisbon exists an important concentration of *pátios* (over than 45 per km²). This important concentration extends to downtown direction. In second half of the 19th century this area was in a process of urban expansion;
- ii) Cerca Fernandina endogenous area: dozens of *pátios* in the historic neighborhoods of Alfama, Mouraria and Socorro. This area was consolidated in the 19th century and *pátios* emerged as urban surplus;
- iii) Eastern Axis: there is a significant concentration of *pátios* (35 to 44 per km²) associated with the East Lisbon industries;
- iv) Western Axis: on the slopes of Alcântara valley and in the parish of Prazeres. This axis prolonged to more remote areas, such as Santo Amaro and Ajuda.

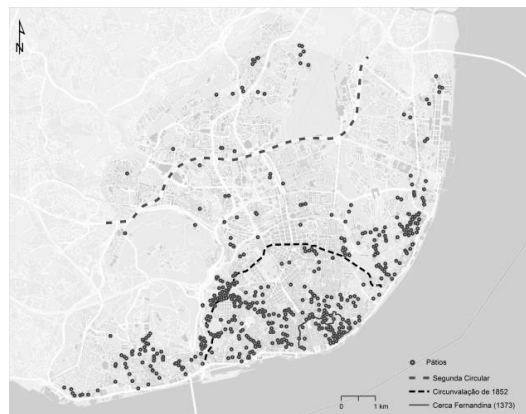

Figure 1. *Pátios*: elements distribution.

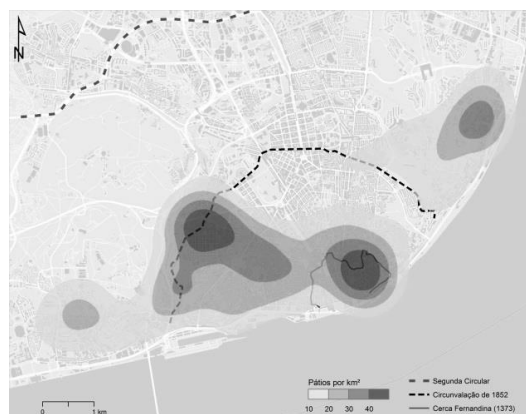

Figure 2. *Pátios*: spatial density (km²).

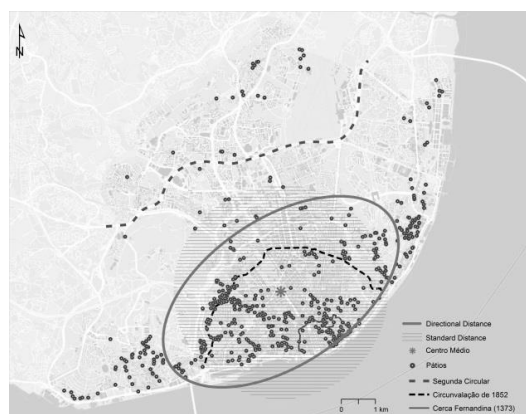

Figure 3. *Pátios*, spatial analyze: mean center, distance standard and directional distance.

End of industrial-housing evolution: vilas operárias

In 1881 was realized an Industrial Inquiry that made critics to industrial housing in Lisbon, specially to the *pátios*. After that, *pátios* lost relevance and were replaced for a new kind of habitation ensembles: *vilas operárias* (cf. Leite *et al.*, 1991).

Vilas operárias were built in devalued land by using cheap material. So, *vilas operárias* were built mainly outside the city in the area of urban sprawl. This period was tender about constructions standards and surveillance. This situation potentiated the economic construction of buildings with one or two floors, repetitive and monotonous.

In this sense, *vilas operárias* were intended to lease low cost for families with low incomes. The *vilas operárias* construction were economic, simple, used inexpensive materials and based on a modular structure, allowing higher densities of occupation and easy expansion.

Thus, the demand to maximum utilization of area to get great profits remained in *vilas operárias* period. However, it should be noted that *vilas operárias* had better living conditions than *pátios* (Pereira, 1994; Leite *et al.*, 1991).

Vilas operárias: morphology

To Nuno Teotónio Pereira the morphological classification should favor the characteristics associated with size and relationship with the public space. In this way, Pereira (1994) classifies *vilas operárias* as:²⁵⁸

- i) Corridor Vilas: exist all over the city, developing directly on the public street.
- ii) Vila generating pátio: houses grouped around a common and discovered place.
- iii) Vila built behind buildings: demarcating the social status of residents. In the building that faced to the public street resided the bourgeoisie, the backyard was left to families with low incomes. This type of vila operária divided the space with a strong social dichotomy. The architectural quality and living conditions were better in the main building, as opposed to the backyard.
- iv) Vila generating street: were often associated with industrial production and near of factories. Some industrial entrepreneurs took the initiative to built vilas operárias, ensuring proximity houses to their workers.
- v) Vila with urban scale: superior area comparing to the previous classifications. This concept of vilas operárias definitely departed from pátios style, although it has not lost the segregated nature (Pereira, 1994).

Vilas operárias: ban, preservation

In the early of 20th century emerged two regulations that defined the construction conditions, namely Regulamento Geral de Saúde (1901) and Regulamento de Salubridade das Edificações Urbanas (1903)²⁵⁹.

These regulations made the buildings construction more demanding, but *vilas operárias* developments were not stopped. This only occurred in the 30's, when the Lisbon Municipality forbade *vilas operárias* construction.

In the 90's Lisbon Municipality created *Gabinete dos Pátios e Vilas* (Bureau of *Pátios* and *Vilas operárias*), which aimed to survey the real number of *vilas operárias* in Lisbon. Accordingly, it identified about 100 *vilas operárias* as *historical and heritage interest to preserve*.

Vilas operárias: spatial analysis

We proceeded to collection and georeferencing of *vilas operárias* built in Lisbon. We identified 364 elements. From the information contained in Figure 4, 5 and 6 we highlight the following results:

²⁵⁸ Authors such as Salgueiro (1981) and Rodrigues (1978) also classified *vilas operárias*.

²⁵⁹ General Health Regulations (1901), and Urban Hygiene and Construction Regulation.

- i) the largest concentration is located in the old western boundary.
- ii) we can identify in Lisbon historic center an axis on the north of S. Jorge Castle. Some historic neighborhoods, like Graça, Mouraria e Alfama have several vilas operárias.
- iii) less relevant: 1) in the East there was a significant concentration of vilas operárias; 2) In the west of the city we can identify a set of vilas operárias extending to the waterfront.

Discussion

In the second half of the 19th century the industrial growth caused high levels of urban growth in Lisbon. In this way, Lisbon faced many problems common to other major European cities (*i.e.* population and urban growth; population density increase; urbanization rate increase; urban space and buildings over-occupation; urban expansion to rural areas; real estate speculation; local administration lethargy; precarious housing construction; neighborhoods without sanitary conditions; urban poverty; mendacity; epidemics, etc.).

Regarding to the housing ensembles analyzed in this work is clear that we are in the presence of different generations: 1) buildings over-occupation; 2) *pátios* dissemination (*i.e.* backyards colonization); 3) *vilas operárias* dissemination (*i.e.* housing ensembles with urban scale).

Figure 7. Temporal evolution.

In parallel, and as the results obtained by georeferencing and mapping of almost 1000 elements, are evident for the following results:

- i) *Pátios* had a higher quantitative and spatial spread than *vilas operárias*. Nevertheless, although *pátios* are more in number, *vilas operárias* generally have higher dimension;
- ii) *Pátios* had higher concentration values in the historic center of Lisbon. On other hand, *vilas operárias* show a spread marked by urban expansion areas (between the nineteenth century and 20th century). In this way, the location of the *pátios* and *vilas operárias* is not fully converged. This is confirmed by mean center analysis, where can be seen *pátios* mean center is located most southern than the *vilas operárias* mean center.

It can be stated that in the transition between the 19th century to the 20th century, private developers have resolved the first major housing crisis in Lisbon. Only in the early 20th century some voices began calling for public policies to promote social housing.

Currently, *pátios* and *vilas operárias* conceal in the urban landscape, in the *non-visible space* of city. With its hidden passages and entrances, these housing ensembles are often imperceptible from the public street, mingling with the other city elements.

Finally, currently *pátios* and *vilas operárias* were presented strongly uncharacterized. The mischaracterization is characterized by the increase of area, allowing dwellings to meet the current demands.

An urban taboo

Marco Falsetti

E-mail: levonraisen@libero.it

Abstract. *The historiography of the twentieth century has always looked to the architectural production of the last century with different critics, while maintaining uniquely, as an unavoidable prerequisite for modernity, the constant reference to the Modern Movement, considered the only parameter and yardstick for any 'value judgment'. As a consequence of this vision, an important part of the projects related to the 'Reconstruction' has long been marginalized from the debate around the contemporary architecture, superficially labeled as the product of an ideological authoritarianism or the aftermath of a broader 'nineteenth-century thought'. Monumental projects like Don Bosco district look significant today, especially if related to the historical period they belong, the Fifties, when most of the interventions on the urban fabric were morphologically punctual and autonomous, probably even more meaningful if we consider that monumentality, that characterizes those projects is a feature obtained through the use of architectural typologies usually unrelated with the idea of monumentalism, and thus they shaped a new idea of city different from both the past and coeval experiences.*

Key Words: monumental districts, countertrend methodology, Don Bosco, urban-integrity.

Monumental district countertrend Rome interruption

Defined through monumental perspectives, dimensionally related to the historical Roman avenues, and philologically connected to the Mausoleum of Alexander Severus, the Don Bosco district in Rome has both the characters of a lithic wing and the obsessive seriality of its housing blocks.

It was mostly planned by Architect Gaetano Rapisardi in the first half of the Fifties, by resuming and developing the "Plan of Rome" made in 1931, and it represents the only discontinuity in the Italian panorama of low-cost housing districts, more related to foreign contexts like France than its Italian coeval experiences, that assume new districts as conflictual realities with the historical urban fabric.

While almost completely ignored by the Italian architectural debate, the Don Bosco district denotes a refined spatial stronghold, thanks to: the monumental dimension of the courtyards and the scenic continuity of Viale Don Bosco (one of the largest axis in Italy); all those elements define an highly discernible morphological area, enclosed by two poles: the Mausoleum and Cinecittà.

The Don Bosco is set on a monumental urban axis, Viale San Giovanni Bosco, that has a length of about 1 kilometre and a half, and which connects the Mausoleum of Alexander Severus to the Basilica of San Giovanni Bosco. This pair of poles identifies what is, in substance, a triumphal street, if we consider the presence of the two thematic depths that open and close Viale San Giovanni Bosco.

The whole axial system, interrupted only by Piazza dei Consoli (which distributes an array of smaller lots), is in fact concluded by Piazza San Giovanni Bosco, where Viale San Giovanni Bosco and Viale Marco Fulvio Nobiliore are tied through the monumental buildings designed by Gaetano Rapisardi, which also bound a space that has no precedent among the public housing estates in Italy, having only few similar cases in Europe, mainly in the countries of the former socialist block.

Viale San Giovanni Bosco's unusual width of fifty meters, in consideration of which would seem more correct to call it 'promenade' (which by definition is opened and

concluded by theme or by a singular architectural episode) is indicative of a strong aesthetic projectual will, which produces, in contrast to the Italian prevailing urban thought, a city-district, both linked to the notions of urban morphology and the Piacentinian idea for the suburb as the sum of large urban systems functionally and formally autonomous but related to the historical urban fabric.

The Plan of Rome made in 1931 originally envisaged the structure of Tuscolano (as it was called the macro area that actually includes the Don Bosco) around a central trident, patterned after a colonnaded square and circumscribed by housing blocks.

The central trident had been planned having as main axis Via Tuscolana, with a branch ending in a widening in the proximity of the rail, and another in a new square. By the latter, in turn, a further, less accentuated trident would have to rise, characterized through a central axis, and interrupted by a large square with government buildings.

The Tuscolano was thought, in this sense, as a homogeneous urban episode, according to the model of the town as a sum of different districts; and thus the Don Bosco was somehow thought to be the typological reference for the southern suburbs, populated by the working class.

Subsequently, for a term of the administration, the uniform project of 1931 was split into two smaller plans, planned at a distance of 7 years, hinged on via Tuscolana. Due to this change Via Tuscolana became a separator element, and also mutated its function from "urban axis" to freeway.

One of the two plans (the one that originated the Don Bosco), was organized around a new axis, parallel to via Tuscolana, and delimited by two thematic polar squares, plus another one in the middle, Piazza dei Consoli, necessary considered the size of the central axis, but also signal of a smaller system of perpendicular streets. However, it remained partially incomplete.

Only one of the two smaller plans was built, creating the district Don Bosco, that reproduces, in a smaller scale, all the features included in the original project for the Tuscolano: in this way focus and theme of the square became the Basilica of San Giovanni Bosco, built between 1952 and 1964 as a result of a competition organized by the Pontifical Commission on May 15th, 1951, on a plot of 17000 square meters donated by the real estate company Tirrena to the order of Salesiani.

The competition was won by Gaetano Rapisardi, who had already worked with Piacentini for the Città Universitaria in Rome (he designed the faculties of Humanities, Law and Political Science) who proposed a building that had both the character of the central plan (expressed by a dome resting on the huge drum) with a basilical type characterized by the great transept.

During the subsequent phases of the project, the nature and the size of the dome were defined, in fact it was lowered and put directly on the drum; then on the main facade three large portals framed by pilasters were opened, a treatment that was later extended to the other elevations with the opening of further portals. On the morning of May 2, 1959, after seven years of work, during an international conference of more than four thousand Salesian Cooperators, present all the superiors of the order, the Cardinal Protector Benedetto Aloisi Masella, consecrated solemnly the Basilica and ten bishops consecrated at the same time the ten altars.

In its final version, the building looks like a rectangle of 45 x 78 meters. The height is 73 meters, including the crypt that is 6 meters below the ground level. The building can be read as two parts, which summarize the basilical type of church and the one with the central plan: the first part stands as a pedestal and measures approximately 20 meters, the latter acts as the crowning, 46 meters and includes the main drum, with a double row of circular pillars, and the smaller drum, the domes, the metal plated terminals and the two bell towers. The facade is divided into seven bays by pilasters (not featured in the first project made by Rapisardi).

The monumental Piazza San Giovanni Bosco (m125 x 185) that opens and concludes the namesake avenue, features the same theme of the colonnaded square included in the Piano

Particolareggiato made in 1942, and enforces the perspectival outcomes through the relational character that binds the church and the square.

The jury of the competition for the Church of San Giovanni Bosco wanted that the winning architect supervised the design of the opposite overlooking buildings opposite in order to achieve a unified image, which is what happened in 1955, when the town gave Gaetano Rapisardi the provision of urban square.

The project made by Rapisardi, aimed to emphasize the homogeneity of the project by using a unified design of the facades of residential blocks, and furthermore by using a sophisticated play of perspectives, such as the narrowing of via Marco Fulvio Nobiliore, which was supposed to put in contact the church to the square, but that was not realized.

The square, Piazza San Giovanni Bosco, is characterized by the constant presence of a massive portico, 8.50 m high, with a distance between the spans of 5.20 m and with the pillars having a section of approximately 1 x 1.20 m. Above the portico there are six floors with a height of 3, 50 meters, are divided into three zones by a continuous band of bulwarks. Each one of these three areas of the elevation is unified vertically through a sequence of small pillars, three times the number of the portico below. The south-west side feature a tower that connects two different lateral buildings and works as a backdrop for Via Calpurnio Pisone.

Originally a large circular fountain was planned to be placed in the center of the square, but only the shape of the base was realized (a circle with a diameter of 40 meters that has the same dimension of the section of Viale San Giovanni Bosco), which originated its current appearance.

A perceived figurative relation with the fascist model of urban planning is one of the reasons for which this district has mostly been considered as a taboo in the Italian architectural debate avoiding to solve, in a rational way, the urban problematics posed by a, highly populated peripheral area.

In the same years were realized three projects of public housing close to the Don Bosco, linked to the idea of the city closer to the dictates of the Modern Movement. The proximity of such interventions, made by INA Casa (the authority for the public housing), emphasizes the diversity of two ways of approaching the plan, one based on large urban signs independent from the urban fabric and influenced by the idea of the functional city, the other on strongly hierarchical parts, which although preserving its autonomy create a "different" kind of city, in which the dialogue with the existing city, while preserving its recognition, is not in terms of conflict.

The Tuscolano I was carried out between 1950 and 1951, and is a collage of different buildings designed by different architects within the same plan (Piano Regolatore Generale), but it does not show an overall urban design. Its boundaries are Via Tuscolana, Via del Quadraro, Via Giulio Agricola and the Park of the Aqueducts. It features intensive buildings and villas.

The Tuscolano II was built between 1950 and 1952 with a strong formalistic will in urban design. The project is by Mario de Renzi, Saverio Muratori and Lucio Cambellotti with Francesco Fariello, Adalberto Libera, Giuseppe Perugini, Giulio Roiseco, Dante Tassotti and Luigi Vagnetti as collaborators.

The Tuscolano III or Horizontal Residential Unit is located in Via Selinunte 49 and was designed by Adalberto Libera and built between 1950 and 1954. The district is enclosed by a wall, the entry is placed in line with Via Sagunto, and underlined by a low arch

The complex consists of 200 apartments (about 1,000 people) on the ground floor, each one with a patio. These accommodations are preceded by a central garden planted with pine trees that contrast with the green of the tiny patios.

Unlike the other sectors of the Tuscolano area, realized by INA Casa, all of which well documented, there is lack of documentation on the district of Don Bosco, both in general terms (general plan, intervention programs, etc) that in specific terms (on individual buildings, but also on the work of Gaetano Rapisardi that is nowadays the best known

architect among those who worked on the Don Bosco Quadraro, mainly known for having designed part of the Città Universitaria in Rome).

Numerous are the causes but mostly related to the ostracism coming from the coeval cultural and political prevailing ideology, hostile towards an idea of the city considered, unfairly, traditionalist and reactionary.

Despite the size of the project, dimensionally larger than any New Town made in the fascist era, there is no trace of the project on the coeval architectural magazines. On the other hand the Don Bosco district has been widely documented by the neorealist cinema, a fact that gives the idea of the project's impact on the collective imagination. The opening scenes of *La Dolce Vita*, fictionally set in the EUR district were shoot in the Don Bosco.

The Don Bosco is in fact very close to Cinecittà, to the Istituto Luce (institute of cinematography) and to the Experimental Centre of Cinematography, and the district has been featured in a countless number of movies since its creation. In fact is depicted in movies like *La Dolce Vita*, *Mamma Roma* and *Fantasma in Roma*, from time to time scenically representative of different parts of the city, all included within the district.

A second reason why the intervention has not been adequately investigated is the incompleteness of the original plan, due to, a number of lacking lots were later completed in a regime of speculative real estate investing. However a huge part of the Italian historiography has proven to be more prone to justify the great failures of urban modernist thought, guilty of making anonymous suburbs, detached from the cities in which the idealistic logic of the great signs has not provided a logical urban thought. As a proof of the persistence of this attitude, also recently published books report the Don Bosco case only as an example of speculative overbuilding: “(..) to better understand both the ethical and urban vision presiding over the system of Viale Etiopia, just a quick comparison with the simultaneous realization (we are in the mid-fifties) in the district of don bosco in the tuscolano neighbourhood. In the building blocks, the different morphological-type models (the urban block in the front courtyard, the tower houses, the tall houses in line arranged in parallel, diamond or herringbone) are used to construct an urban fabric that has a paroxysmal character because the built volumes are designed and matched with each other only to respond to the principle of maximum utilization of the lot”.²⁶⁰

Yet just a quick comparison with the urban projects made under the Fascism is needed to underline that the origin of Don Bosco district is actually linked to a different architectural thinking, related to the notions of fabric and shaped by a concept of monumentality not associated to ideology. Just think of the plan made by Auguste Perret for the reconstruction of Le Havre or the project for the MDM Marszalkowska Housing District in Warsaw in which, both the specialized tissue and monumentality are defined, as in the Don Bosco, through basic buildings, a thought more ancient than the Modern Movement and that is starting to be seen as a solution to the problems of the contemporary city.

European spatial paradigms towards urban infrastructural morphologies

Manuela Triggianese, Fabrizia Berlingieri

Department of Architecture, Faculty of Architecture, Delft University of Technology

E-mail: triggianese-1@tudelft.nl, info@berlingieriarchitetti.it

Abstract. *Because of their impact on urban fabric and economy, infrastructural changes, are key components of complex urban transformations. Large scale interventions, shaping major European cities, are mostly related to the Trans-European Network (TEN-T) policy. The nature of this development results in the increasing evolution of urban hybrids and multi dimensional morphologies within the territories infrastructures cross. They are characterized by aggregations, juxtaposition and super positions of different modality of transport, defining new typologies embedded within the urban scenario and, at the same time, linked to a larger urban frame. This contribution aims to explore how within the new policy EU territorial changes can be supported by research and methods of analyzing urban form and its structural elements. In that sense an integrated design approach to mobility will be presented from the dialogue between theoretical reflection and design practice of infra-urban reconfiguration processes, in order to increase the awareness of the unique challenges of infrastructure and the role of architectural design. From the research analysis of coding Urban Morphological Types (A) to the investigation of Intermodal Knots (B), driven by public-private interests along the high speed line, the paper attempts to enlighten the meaning of new European spatial paradigms.*

Key Words: infrastructure, intermodality, urban morpho-type

Coding urban morphologies

Transitions. From Modernism to EU visions

“Almost all the streets should be straightened and enlarged. They should be extended as much as possible to eliminate too frequent windings. New streets should be driven through all blocks that are longer than 600 feet. At all intersections of streets the corners should be rounded; at all crossroads there should be squares” (Laugier, 1765)

At the turn of the nineteenth century, the unity of the urban tissue, based on the built intertwining of masses and voids, is definitely substituted by the presence of a new figure, the infrastructure, assuming the asset role for the incoming vision of Modern City. As prologues of this condition were standing the XIXth century disembowels operated in European cities’ large interventions on urban body, as the Haussmann boulevards, writing new urban codes based on the rational geometry of accessibility. Inheriting Italian Renaissance axioms, the urban body at the end of the XIXth century was the representative scene of institutional power and at the same time the perfect embodiment of idealistic urban concepts emerging (Vidler, 2011). In few decades the institutional power was substituted by the Industrial Revolution values, however maintaining the same key components to build its own image. In that sense the ideal of urban construction evolved towards a new metropolitan configuration in which the infrastructure acquired a status of autonomous formal entity. The spatial urban perspective defined by urban curtains is overpassed by an horizontal and infinite metropolitan extension, in which nature and artifice became interrelated parts of the whole. The spatial development linked to Industrialization and the process of formal autonomy of infrastructure together reorganized the urban scene in a a system of objects floating in a dialogue through distance. It defines an exploded space (Choay F., 2000 ed.it.), a city carefully dismantled into its components and lying in the openness, where each part becomes singular entity of

dialectic with a totalizing landscape. These characters of the Modern City - the dismantling of urban scene's unity, the giantism, spatial isotropy - generate what Sitte defined as the disease of modern isolation (Sitte C., 1889). "Urbanism will abandon the current street-corridor, and through the path of new developments will create, on a much larger scale, the architectural symphony that need to be conducted. The street-corridor with two sidewalks, suffocated by high houses, must disappear. Cities have the right to be something else that many buildings with corridors". (Le Corbusier, 1924)

Infrastructure becomes, within the formulation of Modern and post modern urban visions, a constant reference, even more a true alter ego to the city itself, duplicating and overcoming it. In this direction proceeds the research of Alison and Peter Smithson that, mostly on infrastructure and its role in contemporary urban development, tried to found a specific design iconography as, for example, in the project for Golden Lane Housing of 1952 or the project for Hauptstadt Berlin of some years later. In Smithson's experimental project the settlement design literally duplicates the infrastructural one. The city raises to a formal simulation of circulation flows, becoming a sort of iconic network mold. The semantic autonomy gained by infrastructure within the construction of urban scene rages, along the last century and up to the contemporary, its own morphology based on elemental figures -as viaducts, flyovers, superficial and underground conducts- strongly conflicting with urban form.

But at the turn of the new millennium we are observing a deep transformation of the figural relationship between infrastructure and urban body. The key factor of this transformation is related to infrastructural proliferation, namely to the exponential growth of networks and transport modes. Major European cities host at least two airports, large harbor areas, several subway lines, traditional rail lines implemented by those of high freight capacity and high-speed. Compared with the amount of infrastructure is also profoundly changed its quality aspect. If in Modernism, in fact, infrastructure constituted an extensive grid of territorial accessibility, today it is increasing in terms of greater intermodal concentration. These two factors, proliferation and higher density, are deeply influencing the change of infrastructural characters, that could be defined as new hybrid morphologies.

Interferences. Infra-urban morpho-types

"Rather the new forms and those inherited from history seem to be able to live within new frameworks of meaning that hide, under the blanket of an apparent familiarity of the daily scene settlement, the multiple and disjoint memberships to the space of flows and the new scales of interdependence with territories at a distance. Thus new settlement morphologies accompany the profound changes that have affected the places of living, producing, consuming and their specific relationships" (Clementi, 2010).

Contemporary infrastructural intersections are mostly envisioning a new European metropolitan scale through the interventions of redevelopment, conversion and expansion of infrastructural lines and areas within urban conditions. Because of the emerging panorama of intermodal transport and the need of physical density, infrastructure cannot be read through individual and autonomous figures as it was in Modernism. Arises, in fact, the problem of new settlement morphologies' materialization, linked to the flow dynamics, which frequently overlap themselves on the stratified territorial frames, generating ambiguous complicities if not outright conflicts.

The proliferation as well as the increasing spatial complexity that these intermodal density bring into the urban scene, make impossible a clear and defined figurative reading. They are merged within the city, mostly relocated in its underground and are more and more presenting the ability to duplicate city itself. For these reasons today we can talk about not single infrastructures, not individual figures, but about new infrastructural grounds articulating urban body and its limits. In that sense we talk about intersections that create new morphologies, in balance between infrastructural and urban spheres. The emerging intersection morphologies have to do with a larger and more complex issue within the

disciplinary debate. It is possible to affirm that intersections represent a key word in the disciplinary framework, that are more and more present within different fields and seen as interactive, hybrid spheres of cultural domain. A semantic intersection we talk is related to infrastructure, urban form and architecture. The semantic hybridizations evolve towards new forms and design configurations in which infrastructure is continuously compared, showing deeply modified in its disciplinary statute. Looking at the main infrastructural and urban transformations happening in EU cities, is possible to enlighten and describe which morphological changes have been defining for the forthcoming years. These interventions are mostly related to redevelopment projects where the infrastructure, exponentially loaded over time, has become a factor of social exclusion, of physics break and, for this reason, of conflict within the social scene. Nowadays these huge transformations are a primary mean of financial attractiveness as privileged sites for new flows demographic and labor, are real engines of economic development and socio-cultural development.

A first case of morphological interference concerns the relation between infrastructure and the recovering and re-appropriation of nature within urban and territorial contexts. The place of the conflict - the ground divided between infrastructure and urban body - is now conquered by an artificial ecology (Allen, 2003), which redraws the cities' ground and internalizes infrastructural figurativeness. In general terms, this trend allows to trace an emerging twenty-first century iconography that appeals to a new arcadia for future scenarios, solving in disappearance, the conflict between infrastructure and urban form. Some examples of this phenomenon could be addressed to the ongoing projects of Avenue 2 for the city of Maastricht or Parque Central in Valencia. Both of them work on the covering of infrastructural lines within urban context, reallocating over them new leisure and green areas. The second case of morphological interference is similar to the previous one and refers to infrastructural interventions in urban conditions. The fundamental choice, in fact, is to reallocate infrastructure in underground spaces (Purini, 2005), creating a sort of infrastructural artificial basements within the cities. Near to the urban subway that builds under the city plan, a physical substrate of mobility interactions. A third form of the intersection between urban body and infrastructure is represented by the concept of threshold, where the infrastructural density appears at the city limits. Indeed these interventions occur in a greater need of surface able to host a dense field of lines, traces, viaducts, building voted to mobility. Patterns that take up more and more impressive bands of liminal territory to the city, becoming no more doors as stations were for the modern city, but real infrastructural thresholds, whereas the increasing extensions fall within a more complex imagery. They constitute, as in the cases of Zuidas in Amsterdam or Euralille, new typological hybridizations between infrastructure, architecture and public space.

In all these morphologies of intersections, that can show a general framework for several ongoing projects in Europe, the role of infrastructural typology emerges with new meanings. Through a process of interdisciplinary synthesis, it appears more complex in configuring new typologies that could be defined as urban morpho types. These present themselves as result of an hybridization process, overlapping for instance three different disciplines such as environment, urban and infrastructural studies, merging together and finding spaces for design interactions. The different disciplines, within the interaction with each other, are weakened. As semantic and figural weakening, which appear similar to state transitions, these new morphotypes are able to weave new scenarios and new compositive configurations in architectural and urban design. The interferences, between infrastructure environment and urban form, are bearers of innovation, for remodeling reading instruments and design methods.

Negotiating urban form

Intermodal Knots. Hybrid Spaces

“Infrastructures allow detailed design of typical elements or repetitive structures, facilitating an architectural approach to urbanism. Instead of moving always down in scale from the general to the specific, infrastructural design begins with the precise delineation of specific architectural elements within specific limits. Unlike other models (planning codes or typological norms for example) that tend to schematize and regulate architectural form and work by prohibition, the limits to architectural design in infrastructural complexes are technical and instrumental. In infrastructural urbanism, form matters, but more for what it can do than for what it looks like”. (Allen, 1999)

The investigation on infrastructural matters becomes a common interests among researchers over the last decades, especially on the topic of High-Speed Railway (HSR), part of the trans-European transport network (TEN-T) policy, and the (re) developments of the hubs along the line. At the city-level, HSR stations emerge as Intermodal Knots that connect different spaces linked to the various parts of the urban surroundings, emphasizing infrastructures’ design potentials and limits (Bertolini, 1996, 2012). The (re) development projects of these hubs raise new urban questions of emerging morphologies – where architecture and infrastructural urbanism are blend together in hybrid configurations across multiple scales.

Furthermore train station area (re) development projects in Europe are assuming new definitions of Typology, as result of the interface between networks and design potentialities for architectural and urban interventions around the node (Peters and Novy, 2012). The notion of Hybrid Typology blends together the issues of flexibility, multi functionality and interconnection between mobility functions and related urban activities. Recent research studies attempt to classify architectural and urban Hybrid Typologies, both in Europe and Asia context, as follow: the hyperpole, the urban connector and the extended hub (Tiry, 2008). These mega-urban structures, as a three dimensional infrastructure, become the interpretation of contemporary spatial experimentation on multi-use buildings that enrich the city’s fabric, based on principle of interconnection between different networks and their capacity to take shape from the intersection between architecture and mobility (Ziedler, 1985; Banham, 1976). Upon taking a closer look at the researches on HSR infrastructural urbanism associated with architectural development in-around intermodal hubs, there is still a line of investigation to be defined in the architectural knowledge: the unfinished and long term (re) configuration processes as current critical issue for the design of HSR station areas across multiple scales.

A large number of strategic National projects, dealing with contextual conditions, such as political and economic constraints (as for example the case of Stuttgart 21 rail station mega-project), are forms part of wider planning initiatives at different policy level and aim at triggering multi-dimensional changes: the (re) development of the station facilities, the interfaces between the infrastructural node and its impact on the urban surroundings and the public-sector strategic interventions and private-sector driven and commercially oriented real estate projects with a longer term purpose in mind. The interaction with local stakeholders deeply influences the configuration of these stations from functioning as truly intermodal nodes to potential interfaces between pre-existing conditions and future urban scenario development (Tesoriere, 2013).

Addressing specific attention to the design process of the HSR stations Torino Porta Susa (Italy), Rotterdam Centraal (Netherlands) and Lille Europe (France), this paper aims to illustrate the typo-morphological design aspects through which infrastructure manages to transform itself from urban dis-connector, that is was in the last century, into connector of hybrid forms. Especially if we consider the overlapping systems of transportation, it is possible to reconstruct a new configuration, both in scale and distribution for each project. The HSR becomes instead the ‘urban connector’ between diverse realities, often addressing to infrastructural nodes an active role of integer of urban and architectural space, in a dynamic layering of multiple scales, in the urban core or at the edge of the City. Torino Porta Susa, Rotterdam Centraal and Lille Europe are representing projects of hinge between living places at different scales, in which the mobility of people, goods and information plays a

central role²⁶¹. The combination of functional and the programmatic flexibility of HSR stations and its environs are often identified through an organization of functional plans or layers of a dynamic system that does not correspond to the different urban shapes in place but to the spatial connections able to generate hybrid conditions. In both vertical and horizontal planes, infrastructure (re) connects interrupted spaces of urban life. Therefore these projects closely link architecture and urban reconfiguration to a markedly political character, which requires the coordination of a variety of planning documents and programs, and also the involvement a great number of actors, by means of negotiation and cooperation between a variety of policy makers and investors. (Terrin, 2011)

Given the variety of scale, economic interests and interaction with the stakeholders (on local, national and international level) that have been targeted, the architectural programs on these projects focus on typological settlement within ambitious master plan, providing a single-building solution, where all activities will be concentrated, for the HSR station in Rotterdam, a multiplicity of buildings in Turin Porta Susa, variably integrated in the urban fabric, and a site with different multi layered urban fragments in Lille.

The station becomes a covered part of the City in Torino Porta Susa, where the linear and horizontal continuum of the structure is a reminiscence of the traditional gallery in the history of the City. (Figure 1) The tracks have been sitting where the boulevard crosses, cutting the city in two parts but at the same time linking both sides through public pedestrian passages. The station is a longitudinal roof that links all the networks and the train disappears from the urban scene below the future Central Spine (D'Ascia, 2010).

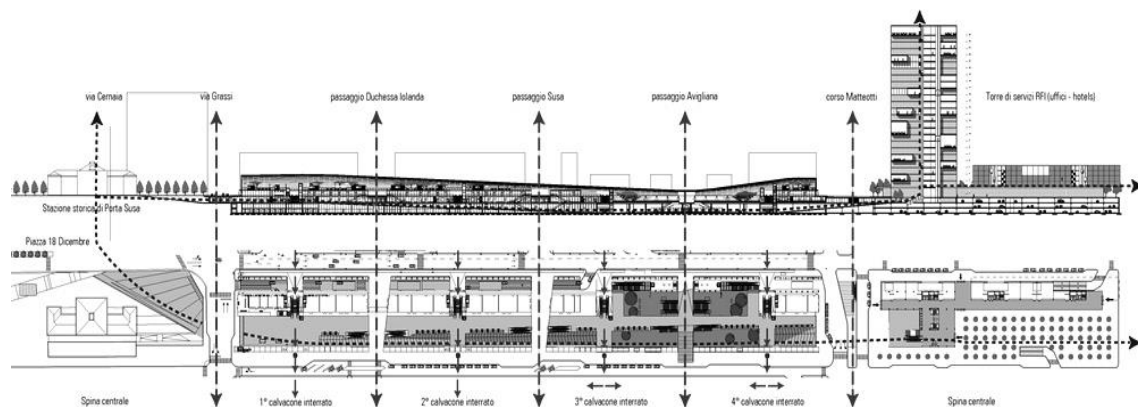

Figure 1. Torino Porta Susa (Silvio d'Ascia Architecture).

The station is a node of urban centrality in Rotterdam Centraal. (Figure 2) In the city of the permanent change, since the post-war reconstruction plans, the master plan for the Central Station quartier (Rotterdam Central District) contributes to the definition of the new skyline for the City. It perfectly fits within the Dutch tradition of integrating land use planning and urban development with transportation planning.

The station belongs to the site in Euralille master plan, the Quantum Leap by Koolhaas. At the beginning of the 90s' Lille was triggered by transportation and urban development around the node Lille Europe. The different networks influenced the position and the function of the station and its relation to the urban environment. As piece of the infrastructure, the station is sitting under high-rise buildings in the middle of the park, where the roof becomes the symbol of the multimodal hub and the envelop of the modern station. (Figure 3) The (re) development of multifunctional area between the two stations, Lille Flandre and Lille

²⁶¹ Torino Porta Susa and Lille Europe have been presented as 'covered part' of the City and as a 'site' by Andrea Heym, Director of International Development AREP, during his lecture The Station is not a Building (23 May 2014, TU Delft).

Europe, is underway after almost twenty years, taking then a central position in the EU urban panomara.

Figure 2. Rotterdam Centraal (Team CS).

Figure 3. Lille Europe (Manuela Triggianese).

Master Planning. Hybrid Process

«It has been recognized for many years now, even by the most rigid planners, than a ‘master plan’, like Utopia, an ideal completed form, can no longer serve the purposes of design in which change and growth may be the essential determinants of order. Forms in their great diversity must become apparent and significant; no single ‘master form’ can do this. Urban design cannot be form alone. Purposeful social commitment must precede all action in the design process without concern for the techniques or shapes through which the commitment may finally be translated into physical reality. (Chermayeff and Tzonis, 1971)

During the last decade the increasingly combination of public policy with private initiatives helps to change the territory of EU cities to promote and position as strategic sites leftover spaces and neighborhoods around the intermodal hubs, located in or out-side the heart of the City. The desire to reconfigure the station and its intermodal character and a number of large real estate projects supported by the Railway Company and private stakeholders contribute to initiate urban interventions for the area. In this context, the City wishes to encourage a renewed ambition by performing larger urban projects around the hub

to implement a coordinated public intention and supervise the work of private actors. Long term ambitions of the urban project – in the ideal form of the Master Plan - pursue the following fundamental objectives: strengthening the status and image of international gateway area, employment hub around the station as part of an overall urban strategy, combining social and functional diversity; take advantage of the excellent accessibility of the public transport to target urban development model based on regional perspectives for the area.

Therefore the complexity, as result of long term purposes for the development of an infrastructural area, lays in the following tasks: the design of an urban project (programming, densities and urban forms, templates, landscape, urban and architectural requirements, requirements for the design of public spaces including lighting design and signage, etc.); the study of multimodal mobility (including the definition of scenarios and traffic plans change and networks modeling the impacts of different scenarios of urban planning and mobility); economic feasibility studies and financial; the possible implementation of the Master Plan (where the architect becomes the coordinator of the process) monitoring the projects (architecture, public spaces, mobility) and its adaptations. In the negotiation of these hybrid urban configurations can be confirmed the Deleuzian assumption « Creation's all about mediators. Without them nothing happens ». (Deleuze, 1990)

These complex issues raise major questions in terms of density and morphology, especially at the district level of HSR stations (Bajard, 2007). Research on high speed railway and the mega projects along the network increasingly proliferate, in relation to the evolution of urban dynamics and different national context. (Bruinsma et al., 2008, Peters et al., 2012) Furthermore contemporary utopian models (master plan) as urban renewal by means of large-scale interventions around nodes, require a particular investigation on decision-making processes and the role of the architectural design within its complexity, especially for the design (re) development of infrastructural areas.

Conclusions

Throughout the different morphologies of intersections, presented as a framework for several ongoing projects in Europe (Berlingieri and Triggianese, 2013), the role of infrastructural matters emerges with new meanings. The issues of interdisciplinary (environment, infra-urban and design process studies) keep configuring more complex typologies that could be defined as new Urban Morpho-Types. They present themselves as result of hybridization, both in spaces and in process, overlapping for instance three different disciplines, linked together in new composite configurations in architectural and urban design interactions.

“Infrastructural work recognizes the collective nature of the city and allows for the participation of multiple authors. Infrastructures give direction of future work in the city not by the establishment of rules or codes (top-down), but by fixing points of service, access, and structure (bottom-up). Infrastructure creates a directed field where different architects and designers can contribute, but it sets technical and instrumental limits to their work. Infrastructure itself works strategically, but it encourages tactical improvisation. Infrastructural work moves away from self-referential and individual expression toward collective enunciation”. (Allen, 1999)

Teaching urban form

Considering how aspects of urban form are taught is of increasing importance as the subject becomes more international and more interdisciplinary. Further, some key figures in the field are retiring, and a new generation of researchers and practitioners needs to be recruited and educated. Finally, the challenges posed by technological advances in data collection and analysis need to be explored. This is a big agenda, and this session can only make a start. We have sought contributions from academic and professional courses, and from different national contexts. We have deliberately sought comparisons, with local innovations being set in wider contexts. But this session does not provide a 'how to' manual for teaching urban form: it questions approaches and demonstrates good practices. Many issues will remain unexplored; but the profile of teaching urban form will be raised for future conferences.

Teaching and Seminar of Urban Morphology in Peking University, China

Xiong Xinkai^{1,2}, Feng Song^{1,2,3}

¹ College of Urban and Environmental Sciences, Peking University, ²Urban Morphology Research Group, CHINA, Peking University, ³Urban Morphology Research Group, Birmingham University. Email: xxk8005@126.com

Abstract. *There are three teaching and seminar activities on Urban Morphology in Peking University, whose academic background is urban geography and urban planning, under the charge of Prof. Feng Song, from UMRG.CN. The first one is the undergraduate course, Introduction of Urban Morphology. The second is the graduate course, Senior Lectures of Urban Form and Culture. The third is the seminar about theory and practice of Urban Morphology in the research group for graduate students. Through the design of curriculum, the research group focuses on important issues, like multidisciplinary background of urban morphology; disciplinary history of Conzenian School, Italian School and Chinese School; method and tips of field work survey; integrated research with practice and multi-cultural comparison and international communication. On the other hand, there are also some difficulties during the urban morphology teaching, like language, field work survey, multi-cultural comparison etc. The paper also gives the future plan of urban morphology teaching in Peking University.*

Key Words: Urban Morphology; Teaching and Seminar; Peking University

Academic Background of Urban Studies and Planning in Peking University

Peking University was founded in 1898, considered as the earliest modern university and the supreme comprehensive university in China. Different from the origin of architecture in technology universities, Urban Studies and Urban Planning in comprehensive university usually derived from geography, focusing on multi-scale urban problems and strategies handling with them.

The academic background of urban studies and planning in Peking University could be retrospect to the Department of Geology and Geography, which integrated Geography, Geology and History from other universities before 1949. In the early time, site selection of industry was the most important research and practice of the department. Through 50 years, the department has developed to three colleges with various subjects (see Fig.1). At present, Urban Studies and Planning in Peking University has the fundamentals of multidisciplinary academic background with the core of urban geography.

Teaching and Seminar of Urban Morphology in Peking University

Similar as the worldwide development of Urban Morphology, despite of its long history in China since 1930s, the academic interest in the study urban form arouse after 1990s considering its influence on urban planning and design.

However, in comparison with the situation in China, the teaching and research of Urban Morphology has played an important role since 1950s in Peking University because of its tradition of historic geography research. Prof. Hou Renzhi, whose supervisor was Sir Henry Clifford Darby, has focused on the historical process of Beijing after finishing his study in Liverpool University. Although the research of Prof. Hou did not use the terminology of Urban Morphology, his concentration had reached some important issues like geographical difference

of urban landscape. Thanks to the corporation with archeological department and opportunity to make early urban planning in China in 1980s, the teaching and research of urban form in Peking University had long-time accumulation especially in these historical cities, which provided profound academic tradition and atmosphere.

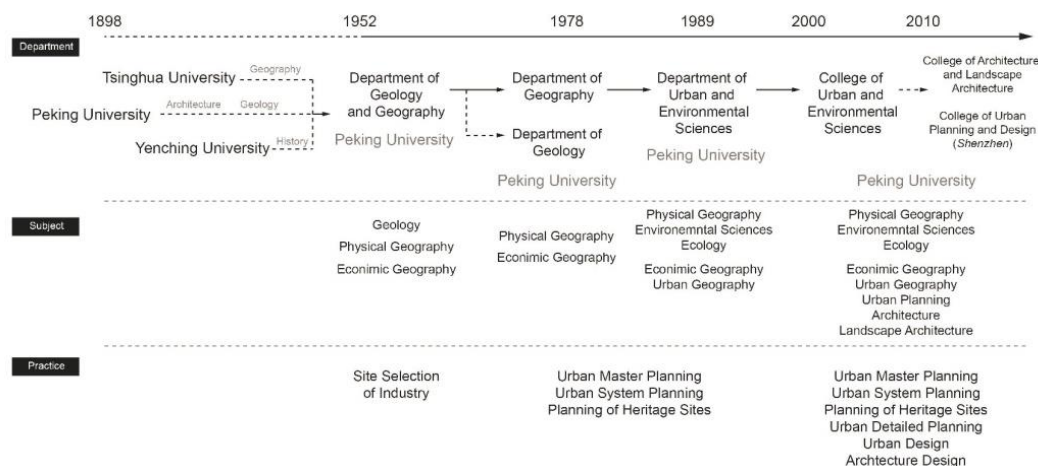

Figure 1. Change of Department, Subject and Practice of Urban Studies and Planning in Peking University.

After his retirement, the rise of urban system and urban structure research to some extent affected the study of urban form in Peking University. These researches focused on the other aspect of urban geography using massive cross-sectional data integrated with the approach of geometrics and GIS. Up to now, these researches have still held the dominant position in urban geography, while the tradition of historic geography has gradually been overlooked because of its “incomplete” academic paradigm.

After 2000, the “culture turn” of Chinese urban geography and more and more highlighted city problems led the rethinking of the urban form study especially influenced by the idea of American urban planning, such as Kevin Lynch. At the same time, Prof. Song Feng got to know the Conzenian academic tradition of Urban Morphology and ISUF. After his academic visit to UMRG cooperating with Prof. J.W.R.Whitehand, he started to found the research group of urban form in China and reestablish the teaching system of Urban Morphology in Peking University.

In the teaching system of Urban Morphology in Peking University, integration of Chinese and European academic tradition seems to be the most significant issues as well as the application of Urban Morphology in the teaching of urban planning. Because of its multi-disciplinary knowledge preparations and its influence on planning practice, the introduction course has been arranged in the 6th Semester of undergraduate students since 2011, given its mid position of the teaching plan (see Fig.2). In addition, the UMRG.CN seminar has been prepared for the graduate students who have deep interest in this field, including: perusal of important academic literature, monographic independent research and academic lecture. In 2013, another graduate course named as Senior Lectures of Urban Form and City Culture was established for the students major in architecture and urban design focus on the application of Urban Morphology (see Tab.1).

The details of these teaching and seminar activities will be illustrated in the following parts.

Undergraduate Course: Introduction of Urban Morphology

Target of the Course

The target of the course is to help undergraduates learn the system of Urban Morphology, including: understanding the key concept of Urban Morphology, comprehending the disciplinary history of different school and applying the terminology and theory in urban form study. Because of the academic background of UMRG.CN, the course focuses more on the concept and theory of Conzenian School.

However, since the course assessment is the independent research of Urban Morphology, ‘Introduction of Urban Morphology’ gradually becomes one of the most important guides for the potential students whose concentration is Urban Morphology and help them build their own academic habits and interests.

Significant Issues of Curriculum Design

The curriculum design mostly follows these principles:

Firstly, the curriculum is divided into 5 parts referring different topics, including: disciplinary history, concept and theory of Conzenian Urban Morphology, basic introduction of building typology and cross-culture research. In these 5 parts, Conzenian Urban Morphology is the most important one, which leads the mainstream of the introduction course. In the curriculum design, Chinese local urban morphology study is also included to compare with the classical ones.

Secondly, the arrangement of the course follows the logic to present the academic context of urban morphology. The origin and development of urban morphology is designed to present first, dating back to the late 19th Century Germany geography. Then, the case study of Alnwick is designed to present after the disciplinary in order to use a classical case study to illustrate the terminology system of Conzenian Urban Morphology and help students understand what the

town-plan analysis is and how to make it. After the case study, concept of urban landscape, building typology and cross-culture research are designed to present more recent research results of the concept, theory and case study in the field of urban morphology(see Tab.2).

Thirdly, the course includes lecture section and discussion section. There are totally 12 lectures and 4 discussions in one semester. The lecture section is mostly prepared by Prof. Song Feng, but the building typology course is designed as the joint teaching with Southeast University. Prof. Deng Hao has been invited to present lectures of his research. The discussion section requires the student to read the classical paper in such topic and presents their idea based on these literatures. The topics of discussion include disciplinary history of urban morphology, Alnwick study, Conzenian and Italian school urban form study, approach and significance of cross-cultural research. All students are required to make 4 paper reviews in each discussion course and at least make 1 presentation for their idea.

Finally, the course assessment needs the students to take the independent research and make the field research work(see Fig.3). This assessment could help student take some practice in the field work and make some brief urban morphology study integrated with just learned theory and concept independently. The assessment also could lead them to understand the urban landscape around them which will help them in their future work of urban studies and planning.

Success and Experience

This course is one of the few urban morphology courses for undergraduate students in China. Although the course just went through a few years, there also exists some success and experience which could be shared all around the world:

1. It is not a good idea to present the concept and theory first, because it is hard to understand for new learners. Presenting the disciplinary history and classical case study will help them where these concept and theory come from.
2. Reading classical papers plays the most important role of teaching because it could give more details of the study. However, it is also hard for students to read the paper without any guides. Some papers could be introduced in the lecture part to help students be familiar with it.
3. Field work and independent research are important for the students who are new in this field. This could help them find their own academic interest and better understand the cities at least.

Graduate Course: Senior Lectures of Urban Form and City Culture

Target of the Course

The target of the course is to help graduates who only want to grasp the basic idea of urban morphology which could help them in the field of urban design. Most students taking this course learn architecture when they are undergraduate students. This course focuses more on how to help students understand the context of city, cultivate their capacity and integrate some idea into practice.

Significant Issues of Curriculum Design

The curriculum design mostly follows these principles:

Firstly, the curriculum is divided into 5 parts referring different topics, including: concept of urban morphology, Conzenian School Urban Morphology, Italian School Building Typology,

urban morphology and city culture: cross-cultural and morphogenetic approach and application of urban morphology in urban planning and design. Different from the undergraduate courses, application of urban morphology becomes the most important part here.

Secondly, in the arrangement of theory teaching, the lecture is designed not only to illustrate the concepts but also more on how urban morphology could help in urban studies and urban planning. For example, morphological process is related to how city culture is formed and urban landscape unit is related to the site and context as the basis of urban design.

Finally, the course assessment is an independent research or design works based on urban morphology. This requires the students integrate urban morphology with their own academic interest and design practice, which could help them better grasp the critical part of urban morphology.

Table 3. Curriculum of ‘Senior Lectures of Urban Form and City Culture’.

Week	Arrangement	Description
1	Chapter 1. Concept and Theory of Urban Morphology	Basic Concept, Disciplinary History Chinese Urban Form Research
2-4	Chapter 2. Conzenian School Urban Morphology	Case of Alnwick and Conzen’s Achievement Conzenian School of Urban Morphology
5	Chapter 3. Italian School Building Typology	Italian School of Building Typology Concept and Theory of Typological Process
6-7	Chapter 4. Urban Morphology and City Culture: Cross-cultural and Morphogenetic Approach	Urban Landscape Unit/Urban Tissue and their Relationship with City Culture Cross-cultural Comparison of Urban Form
8	Chapter 5. Application of Urban Morphology in Urban Planning and Design	Application of Urban Morphology in Heritage Conservation Planning and Urban Design
Course Assessment: Independent Research or Design Works based on Urban Morphology		

Success and Experience

This course is not designed for the graduates whose concentrations are urban morphology but the ones who need it in their design or research. This course is the new one for the graduates major in urban design but it actually receives the good effect. The success and experience of this course maybe more helpful for most colleges of urban planning and urban design:

1. It is helpful to integrate existing concept and theory with the urban planning practice, especially for the students who need urban morphology but not take the research.
2. It is important to help more graduates learn the idea of urban morphology, because the idea will be taken into planning practice which could give more opportunities for the scholars to bridge the gap of research and practice in the future.

UMRG.CN Seminar: Theory and Practice of Urban Morphology

Target of the Seminar

The target of the Seminar is to help graduates who are interested in urban morphology and want to take deeper research. Most students in the seminar have taken the course “Introduction of Urban Morphology” when they are undergraduates, so they have a clear view of what is urban morphology.

The seminar is not only for the graduates but also for the researchers from all over the world who are interested in urban morphology. The role of the seminar is to provide the opportunity of academic communication for both researchers and students.

Arrangement and Topics of the Seminar

The seminar is divided into three parts: classical literature review, lecture and thematic study (see Tab.4).

The target of Classical Literature Review is to read the paper by former famous scholars more carefully in order to find important ideas and details critical to present research. In this seminar, 3 books are selected for reading: M.R.G.Conzen's 'Alnwick, Northumberland: a study in town-plan analysis' and 'Thinking about urban form: essays on urban morphology' and Caniggia's 'Architectural Composition and Building Typology: Interpreting Basic Building'. The work of Alnwick is the most important literature for the new comer. A lot of detailed review has been done to help learn Alnwick's academic point(see Fig.4).

Despite the literature review, lectures are also important in the seminar. M.P.Conzen and J.W.R.Whitehand have been invited to give the lectures in 2011 and 2013. In the seminar, the lecture becomes not only the way to present the knowledge of Urban Morphology, but also the important opportunity for scholars across the world to communicate with each other.

Thematic study is the most important topic in the seminar. Until now, 4 theme researches have been done: Urban Landscape Analysis of China after 1949, Urban Morphology and City Problems, Urban Morphology and Heritage Conservation, Chinese Urban Morphology Research. The cities of case study are across the whole country, e.g. Beijing, Shanghai, Jiujiang, Macao and etc. Thematic study is important for learning Urban Morphology, because it helps graduates cultivate the research skills and review the concept and theory of this field.

NO.	Arrangement	Description
Classical Literature Review		
1	Conzen, M.R.G. (1960) Alnwick, Northumberland: a study in town-plan analysis, Publication No. 27, Institute of British Geographers, London; reprinted with minor amendments and Glossary, 1969.	Detailed review of Conzen's approaches, terms and research details in the study of Alnwick.
2	Conzen, M.R.G. (2004) Thinking about urban form: essays on urban morphology, edited by M.P. Conzen, Lang, Oxford.	Detailed review of Conzen's original idea of Urban Morphology and other case studies.
3	Caniggia G, Maffei G L. (2001) Architectural composition and building typology: interpreting basic building[M]. Alinea Editrice.	Detailed review of Canaggian original idea of Building Typology.
Lectures		
1	M.P.Conzen in 2011	Cross-cultural Comparison of Fringe Belts
2	J.W.R.Whitehand in 2011, 2013	Conenian approach of Urban Morphology Research in China(Beijing, Pingyao, Guangzhou)
Thematic Study		
1	Urban Landscape Analysis of China after 1949	Case Study: Shenyang(<i>Wu Menghe</i>), Yuxi(<i>Dai Ying</i>), Shenzhen(<i>Xiong Xinkai</i> , <i>Shi Chunhui</i>), Beijing (<i>Shi Chunhui</i> , <i>Dai Ying</i>), Shanghai(<i>Xiong Xinkai</i>), Chengdu(<i>Ma Yandi</i>)
2	Urban Morphology and City Problems	Physical Environment Study (<i>Liang Yuecong</i>)
3	Urban Morphology and Heritage Conservation	Case Study: Kuling Town(UMRG.CN,J.W.R. Whitehand and S.M. Whitehand), Macao(<i>Liang Yuecong</i> , <i>Xiong Xiao</i>), Beijing(<i>Xiong Xinkai</i>), Kaiping(<i>Liu Hao</i> , <i>Xiong Xinkai</i>)
4	Chinese Urban Morphology Research	Zhao Zhengzhi's research work(<i>Song Feng</i> , <i>Dai Ying</i> , <i>Shi Yanhui</i>)

Success and Experience

This seminar is designed for the Urban Morphology research student and scholars. It is the most common way of communication for the researchers concentrating in Urban Morphology all over the world. The success and experience of this seminar maybe helpful for the foundation of similar type of Urban Morphology Seminar:

1. It is helpful to review the classical literature again and again, because the most excellent case study has not been transcended. Therefore you can get a lot of information from the old paper about the idea, viewpoint, academic history and skills in the field of Urban Morphology. On the other hand, the more you know about the classical literature, the more you understand the future research.

2. It is important to get group research, because the students can share more information through the same topic and find newer information about it.

3. No matter how large the cultural difference is, cross-cultural communication of the viewpoint shows its significance for future research.

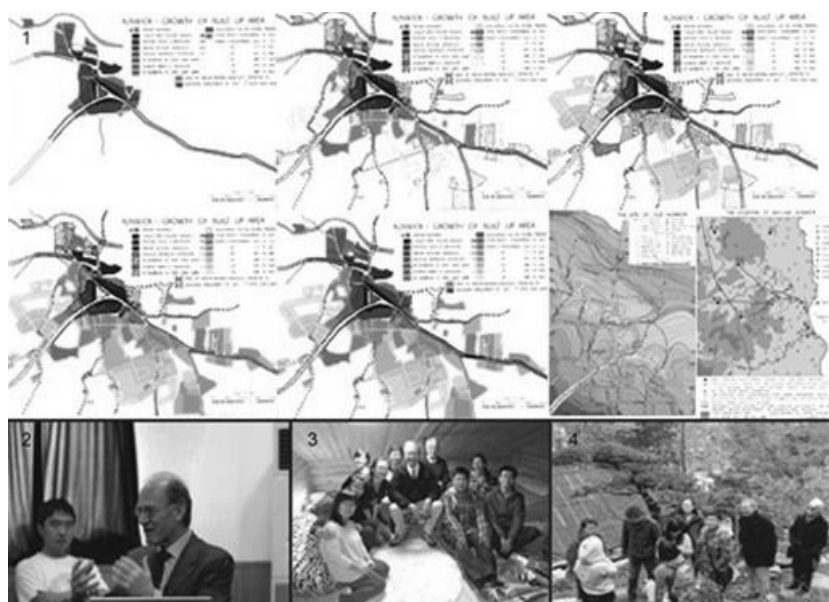

Figure 4. Picture of the Seminar (1: Research Result in the Seminar; 2: Seminar Lecture by M.P.Conzen; 3,4: Field Work with J.W.R.Whitehand and S.M.Whitehand).

Conclusion and Discussion

Difficulty faced in the Teaching and Seminar

Although the teaching and seminar of urban morphology in Peking University has received satisfactory results, a list of difficulty also appears in these years.

The first difficulty is the language in translation of glossary and urban history. In the introduction of Alnwick study, the students appeared very confused to some glossary which is easier to understand in different cultural background, such as burgage, town-plan etc. However, the glossary and some terms related to urban history and institution could not be easily changed into another one because of the loss of cultural information. For example, the concept of “plot” could not just transplanted into Chinese term “dikuai”(地块) without any notes, because the “plot” especially “burgage” contains more important information of morphological period.

The second difficulty is the multidisciplinary teaching, mostly the gap between geography and architecture. Conzenian School and Italian School have different academic background with different academic habit and knowledge. However, in actual urban morphology study, it is more important for researchers to get a comprehensive and multidisciplinary view. This requirement is quite difficult for students if they want to get more achievement.

The third difficulty is the field work survey. Actually, the field work requires the most experience in the whole process of research. However, for the young people who are new to this field, the details in the landscape are hard to find and understand. The teacher also does not have enough vitality to guide each student carefully. Thus, it is necessary for the experienced scholars to prepare a Guide Book of Investigation which could help new students get some useful skills in field work.

The fourth difficulty is multi-cultural comparison. It is not only the problem for the students but also for all scholars. To cultivate more future scholars in urban morphology, international communications are critical especially for young students, including: visiting research, global cooperative study etc.

Further Discussion

Urban Morphology is a “new” research field with more than 100-year academic history. However, the teaching of urban morphology is even “newer” because of its unsystematic state. There even not exists a whole textbook referred to urban morphology. Thus the share of teaching experience is more important for our common future of urban morphology giving the fact of raising number of ISUF members and papers.

The teaching and seminar of Peking University only have a short history. Our research group is also new to this field. Therefore it is significant to build more close and global relationship of each university offering courses of Urban Morphology considering the cross-cultural nature of this research field.

The relations between research and practice

In January 2013 Michael Conzen, then president of ISUF, launched a task force to strengthen the relation between urban morphological research and planning practice. Subsequent responses to accounts of progress of the work, published on the ISUF website and in *Urban Morphology*, including an exceptional number of Viewpoints, confirmed that there was a latent body of opinion and experience which seemed to be waiting for a vehicle for its diffusion. The papers in these parallel sessions confirm the extent to which urban morphology has been applied in practice in wide variety of countries and through a diversity of practice instruments which range far beyond those few western countries which have hitherto dominated the field. This broadening of the context also responds to a major intention of the embryonic Porto Charter and it is hoped that it is a start to a new and fruitful chapter in ISUF's endeavours.

Ivor Samuels

Making a case for the broadening of the urban morphologist's battlefield - the impediments for small-scale development in Miami-Dade County

Eric Firley, Andrew Frey

School of Architecture, University of Miami.

E-mail: efirley@miami.edu

Abstract. *Following Moudon's work on the history and philosophy of the ISUF (International Seminar on Urban Form) movement, urban morphology can be described as the study of the physical form of cities and the process of city-making. Particular emphasis is given to the notion of time and the importance of the single lot as the fundamental unit of evolutive analysis. As a professional and foremost academic set of methods, urban morphology functions empirically and descriptively, even though the complexity of city-making, its multi-disciplinary character and behaviorist interdependencies do not facilitate the scientific proof of causalities. This paper further explores the discipline's normative challenges, particularly on the base of the above-mentioned positivist limitations, but also on the background of implementation issues for the present. To what extent, and for whom, can or should common goals be defined? Which ones are crucial for the creation or retention of an urban environment that does not mock the fundamentals of what we call "urban grain"? How can we have an impact on city- and policy-making without losing the freedom of a neutral academic discipline? As a very tangible example of one of the discipline's allegedly most important issues, the one of scale, the paper discusses legal obstacles to small-scale development in Miami-Dade County. Informed by Moudon's definition of the city as "the accumulation and integration of many individual and small group actions" (Moudon, 1997, p. 3), the authors address the current virtual impossibility of implementing this definition due to systemic impediments to small development.*

Key Words: normative challenges, small-scale development, Miami-Dade County, policy implications, implementation issues

Introduction

Initially, this call for papers was perceived as a simple opportunity to study and raise awareness of a very specific development issue: legal obstacles to small residential development in Miami. On second thought, the authors questioned the obviousness of this endeavor, sensing that such a non-historic analysis of the development processes falls outside of the canon of academia.

To test this intuition and make it part of the paper, we explored all the abstracts from the past eight years of "Urban Morphology", a leading publication in its field and the one closely associated to this conference. How many of the 64 contributions dealt with a similar topic?

Only a few articles -- such as "The morphological dimension of municipal plans" (Volume 10.2, p.101-113) and "The persistence of suburban centres in Greater London" (Volume 14.2, p.85-99) -- genuinely extended their analysis of historic urban development processes into the present. Several other articles mentioned the issue, but did so abstractly, without analysis of specific contemporary forces on development, as if these forces -- including economic constraints and legal requirements -- were no longer relevant to city-making.

A similar exercise for the journal "Urban Design International" revealed a higher percentage of papers that examine current conditions. This suggests the discipline of urban morphology (at least for the active contributors of the eponymous journal) is still perceived as a specialization in a historic understanding of urban development, rather than in urban development as such -- past, present, and future.

This is not surprising given Moudon's characterization of the movement as originally confined to geographers, but it underscores her concerns regarding the discipline's further evolution and impact. Jeremy Whitehand, editor of "Urban Morphology", has repeatedly published similar reflections, such as "Making connections" (Volume 16.1, Editorial Comment) and "Towards a more integrated approach" (Volume 10.2, Editorial Comment).

We would like to suggest possible reasons for this tendency of urban morphology to focus on historic development patterns and the important role played by laws and procedures, but not extrapolate such importance to present and future development. Keep in mind that the below possible reasons reflect the personal opinions of an urban designer and a developer, and furthermore are likely not reflective of geographers, planners, or architectural historians.

(i) As mentioned by Moudon, urban morphology as a discipline can be understood as a critique of and reaction to Modernism, and specifically Modernism's ambivalent relationship with history. Studying the past is hence not only a crucial methodological component, but also a professional and even political statement.

(ii) Historic research and contemporary research differ in methods, skills, and sources, and they attract different kinds of scholars. Contemporary research particularly lacks previously-published work, and its primary sources -- communications with developers and designers -- can be full of colorful and evocative "marketing language" that obscures relevant details like legal obstacles.

(iii) The most recent generations of city-makers -- developers, planners, designers, engineers, lawyers, etc. -- are most familiar with large-scale interventions. From the famous city-extending projects of the second half of the 19th century (Barcelona's Eixample, Vienna's Ringstrasse, Castro's Plan for Madrid, etc.) to Germany's Siedlungen of the 1920s to post-war public housing projects, urban planning academia has been preoccupied with "big power" and its implementation, preferably of visionary character.

However, the plain fact that a large-scale plan was implemented (often because the relevant government was persuaded to change laws) does not prove that the content of the starting vision was the only or even most important determinant for its final outcome. It may be that the large-scale state of mind obscures and underestimates some of the aspects of development that were actually operative. Regarding developments (especially vernacular ones) in the more distant past, physical, economic, and legal "details" are -- in contrast -- considered of crucial importance, details such as building materials (e.g. wood beam strength in row houses), material prestige thinking (e.g. Shanghai Shikumen), property tax calculation (e.g. the width of houses in Amsterdam or Charleston), or laws regarding inheritance (e.g. Tokyo mini-houses). Yet for contemporary projects only the conscious design intent seems to be relevant.

This point leads to two contradictory conclusions: on the one hand, the machinery of large-scale development has prevented the emergence of new types of vernacular architecture, or such types have emerged but a large-scale state of mind has clouded our ability to detect and analyze them.

(iv) Architects often view their work primarily as externalizations of their vision, regrettably constrained by parameters. An architect is given certain parameters by the client or building codes or engineering calculations, and after a brief analysis, the architect creates a form and space that accomplishes the parameters and expresses creativity. It is not central to his work to examine the source of the parameters, or to question them. Unlike an economist or a planner, the architect is not interested to know how economic and legal forces influence behavior and outcomes. This is also true for urban designers. For good or for bad reasons many designers try to force his or her will as a product on the environment, rather than to see design as a process of internalizing exterior forces.

To summarize and tie back to the main thrust of this paper, we have tried in this section to understand possible reasons that urban morphology has not paid special attention to the contemporary development process, including obstacles economic, legal, and otherwise. The next section will scrutinize exactly such obstacles and how they shape development using the

case study of a single product in a single US local government: new small residential construction in the City of Miami.

Legal obstacles to small residential development in Miami

New small residential construction faces many obstacles, some inherent in its small size (i.e. lack of economies of scale), but many others artificially imposed by law. Legal obstacles come in three flavors: 1) make small buildings physically impossible, or 2) increase cost or 3) decrease revenue. Often one obstacle will both increase cost and decrease revenue, for example required parking drives up a small building's construction cost and reduces its net square feet (or, because required parking is usually prescribed on a per-unit basis, it steers a small developer to subdivide the building into fewer, larger units).

Obstacles result from laws at every level of US government: federal, state, and local laws, regulations, unwritten policies and interpretations. Because the legal obstacles occur at varying levels of government that do not coordinate, the obstacles are difficult to catalog and their effects difficult to isolate.

We provide this case study of Dade County, to show a few of the many obstacles faced by small developers, explore their effects, and ask the reader to imagine these problems multiplied across all the cities in the US, all its counties and states, and countless federal laws.

Federal Regulations Regarding Permanent Debt

Obstacle: An example of a legal obstacle at the federal level are regulations regarding how the government buys permanent debt (long term, not construction debt) for small residential buildings with up to four units. The federal program is very useful if you want to build a building with up to four units, but penalizing for five or more.

Law: The program is intended to promote home ownership, and the US federal government buys notes through its subsidiaries Fannie Mae and Freddy Mac to give an additional incentive to private banks to make loans for owner-occupied buildings: a guaranteed "secondary market". Because the federal government's desire to promote home ownership is so great, the program is "over-inclusive" (to an extent) so as not to exclude houses that happen to have a "granny flat" or other accessory unit. Fannie Mae and Freddy Mac will buy a note for buildings with up to four units.

Effect: How does the secondary market for permanent debt affect new construction of small rental buildings? Banks are more likely to make a construction loan if they know that, at the end of construction, there is more likely to be a buyer (or refinance) to pay off the construction loan with permanent debt. So there is more construction debt for buildings up to four units, but less for buildings with five units or more.

It is a legitimate concern that this program creates "moral hazard" for one- to four-family home ownership. However, even if the US government is in the business of creating moral hazard, it should be acknowledged that the four-unit "bright line" regulation has a secondary but significant negative effect on small but more dense development.

State Fire & Building Code

Obstacle: At the state level, a key legal obstacle is the state building code requirements for the number of exits that a building must have. A tower with a large floor plate can absorb two stairs, but a small building ends up mostly stairs.

The number of exits – and thus separate stairs and corridors leading to exits – is another example (like required parking discussed below) of a "two-point swing" in the wrong direction for small developers: stairs increase construction cost and reduce each floor's net square feet.

More specifically, for a small building, the jump from a single exit to two stairs, corridors, and exits can be catastrophic. Assume a stair occupies about 200 square feet per floor. In the

City of Miami, a residential tower in the most dense and intense zoning area (T6-80) can have a floor plate up to 18,000 square feet (Article 5, page 41). One stair occupies 1% and two stairs occupy 2%, a difference of only 1%.

However, most of the city is platted into lots of 50 feet wide. Assuming a building with zero side setbacks (permitted in T4, 5, and 6) and 60 feet deep (a typical apartment unit is 30 feet deep), its floor plate is 3,000 square feet. One stair occupies 7% and two stairs occupy 13%, a difference of 6%. So state egress rules have a potentially 600% greater impact on the assumed small typology than on the large tower.

In Florida, laws regarding the number of exits come from both the state's adopted Fire Prevention Code and its Building Code. The requirements differ in each code, so must be read carefully to find the small area where they overlap. If a building design meets the requirements of one code but not the other, it must have two stairs (or more).

Law: Florida Fire Prevention Code Section 30.2.4 states that for new apartment buildings "a single exit shall be permitted in buildings where the total number of stories does not exceed four" subject to a maximum of four dwelling units per floor and a maximum travel distance of 35 feet. The building must have 0.5-hour fire rating between units both horizontally and vertically, and must have an automatic sprinkler system. Corridors and exit stairway must have 1-hour fire rating with self-closing doors. The stair may not serve more than one-half [sic] story below the level of exit.

Florida Building Code Section 1021.2 states that "only one exit shall be required" for Group R-3 occupancy buildings (one or two units) and certain other occupancies. An occupancy is a space with a specific use within a larger building. Such occupancies are subject to a maximum number of occupants (or dwelling units) per floor and a maximum travel distance to the exit, reproduced below.

Table 1. Story, occupancy, maximum occupants

Story	Occupancy	Maximum Occupants (Or Dwelling Units) Per Floor And Travel Distance
First Story Or Basement	H-4, H-5, I, R	10 Occupants And 75 Feet Travel Distance
Second Story	R-2	4 Dwelling Units And 50 Feet Travel Distance
Third Story	R-2	4 Dwelling Units And 50 Feet Travel Distance

Footnotes state that "basements with a single exit shall not be located more than one story below grade plane", and third story R-2 occupancy may have a travel distance of 100 feet if equipped with an automatic sprinkler system and provided with emergency escape and rescue openings.

Effect: While the Fire Prevention Code suggests that a building may have up to four floors with a single stair, the Building Code limits it to three stories. (Both require that the building be equipped with an automatic sprinkler system, in itself a large cost.) Thus for a small building with five or more units per floor, or more than three floors, it must double the number of stairs, corridors, and egresses.

County Water & Sewer Regulations

Obstacle: At the county level, the small developer faces formidable obstacles in the regulations promulgated by its Water & Sewer Department ("WASD"). According to John Hall, a civil engineer in Dade County for decades and a leader in its development industry, "WASD regulations are our community's biggest obstacle to economic development" (2014).

More specifically, WASD regulations treat large urban towers, large suburban subdivisions, and small urban buildings the same when it comes to forcing developers to upgrade off-site water and sewer mains. Large developments can absorb such exactions, which can easily run into the hundreds of thousands of dollars, but small developments cannot.

Law: WASD rules state that for any new construction, addition, or even change of use, all surrounding water and sewer infrastructure must be upgraded to meet current standards. WASD regulations Section 2.04(2), paragraph (e) states that, when property is “redeveloped, its use changed or otherwise improved”, any water facilities serving the property must be improved “so as to comply with prevailing Department standards, pursuant to paragraph (d)” and subject certain exceptions “in the flow charts of Exhibit A.”

This requirement to upgrade is triggered whenever the water main serving the project does not meet current standards. Per Exhibit A, Chart F-2, for low- and medium-density residential (defined as townhouses or apartments or condos), the current standard is set at 8 inches, and anything smaller must be replaced. Per Exhibit A, Chart F-3, for high-density residential the standard is set at 12 inches. In both cases “an offsite extension may also be required”.

This requirement to upgrade applies not only to immediately abutting mains, but also off-site mains and even secondary services to other properties. Paragraph (d) states that a developer must install a water main that meets current standards “along one entire boundary line of said property [that] abuts a public road” as well as “any required off-site mains” and secondary services to “abutting properties”. The Department “may also require said Developer to install additional water mains as the Department may deem necessary to promote the public interest” in accordance with Exhibit A.

There is an exception in paragraph (e) that states “the Department may, at its sole discretion, perform additional infrastructure analyses consisting of field investigation of flow and pressure provided by existing mains for a period of no less than seven (7) days to determine if capacity is available”. The Department may determine that capacity is available and no water facility improvement is required if there is an existing building with a change of use but no increase of total building square feet and either 1) an increase of “daily rated gallonage” of less than 50%, or 2) the change of use will not cause “a reduction below 750 GPM at 20 PSI residential pressure in the level of domestic and fire flow service”.

The Department may still determine that no water facility improvement is required, but only if additional criteria are met, listed in paragraph (e) and Exhibit A. However, such criteria are only for re-occupancy of bays in retail centers and industrial parks, and new construction of single-family, duplex, and commercial and industrial buildings of up to 5,000 square feet. The criteria do not include apartment development of any kind.

Effect: These water and sewer regulations are unreasonable in many ways, but for our purposes they are a clear obstacle to small development. The regulations give WASD wide discretion regarding single-family and duplex construction – which uses water and sewer infrastructure least efficiently – but not regarding small urban buildings.

This means that, for a small urban development that happens to occur on a street with a water main smaller than eight inches, on at least “one entire boundary line” the developer must upgrade the off-site urban water and sewer network as if it were building new mains and services in a virgin green-field area on private property. The urban water and sewer network is under existing roads that must be closed, and the old pipes must be removed, neither costs that burden a suburban developer. Furthermore, the small developer must upgrade the main and services until it intersects with a main that meets current standards, which may be several blocks.

City > Density (Units Per Acre)

Obstacle: Miami zoning in certain areas permits a maximum density so low that the number of units is less than the existing building (for redevelopment) or does not correspond to the permitted maximum square feet (for new construction).

Law: Miami zoning T4 permits a maximum density of 36 units per acre (Article 5, page 17).

Effect: Miami is platted into lots that are typically 50 feet wide and 100 feet deep, and at least 1,000 acres are zoned T4. Thus on a typical lot, T4 permits four units. T4 also permits a maximum height of three floors and maximum lot coverage of 60%, and does not require a

minimum side setback, which sounds like what are known in the US as “brownstones”: small attached buildings divided into apartments.

Much of Miami’s T4 area is currently developed with one- and two-story rental apartment buildings built in the 1920s and 1930s with very poor quality and thus nearing the end of their useful lives. These areas are ready for the next increment of urban development, which would be three-story buildings.

However, most of the existing buildings have at least five units. A common building type is a one-story apartment building with five units in a row perpendicular to the sidewalk. Thus while such a property could be redeveloped into a building three times the current height, the owner would lose at least one unit.

In the less common case that a lot is vacant, the owner could build a building with a floor plate of 3000 square feet (60% lot coverage) times three floors, for a total of 9000 square feet, but could divide it into only four units. Each unit would be 2250 square feet, which is twice the average unit size in a typical rental apartment building, and not marketable or financially feasible.

City > Parking (Spaces Per Unit)

Obstacle: Miami zoning requires an amount of parking spaces per unit that do not fit on small lots.

Law: Miami zoning requires 1.5 spaces per unit (Article 4, Table 4).

Effect: Assume a small property owner has a lot that is 50 feet wide and 100 feet deep and is zoned T6-8, which permits 150 units per acre (Article 5, page 29). The owner wants to develop a small rental apartment building with eight units, which require 12 parking spaces.

Each space is approximately 10 feet wide and 20 feet deep and the driveway along the 12 spaces is 120 feet long (10 feet multiplied by 12 parking spaces) and 22 feet wide. Clearly a driveway that is 120 feet long does not fit on a lot that is 100 feet long, and 5040 square feet of parking spaces and driveway do not fit on a 5000 square feet lot.

This effect does not apply to large buildings that can fit multi-story structured parking garages. Thus the law is a disproportionate burden on small buildings. Furthermore, it is not even a problem of cost or income, the required parking for a modest apartment building physically does not fit on Miami’s typical platted lot.

Conclusion

We hope the above-listed obstacles and their effects are self-explanatory. Our motivation in discussing them in an academic paper is to insist on the relevance of external forces and processes for understanding urban change.

Though it is only one small example of this process-focused (not product-focused) approach, small residential construction in Miami makes two important points. First, this case study provides a road map for how to detect and document many systematic obstacles to a particular urban morphology.

Second, it helps bring some attention to small urban buildings, a building type overlooked in recent decades, as part of a broader effort to shift focus away from large, master-planned projects and toward smaller, interdependent interventions, an effort joined by developers like Jim Heid (2012), planners like Victor Dover (2011), architects like Brian Phillips at ISA (2013), writers like Robert Dalziel and Sheila Qureshi (2012), Howard Davis (2012), and Ed McMahon (2012), and organizations like ULI (through its small scale developer conferences), the National Trust for Historic Preservation’s Green Lab, Lean Urbanism, and the California Infill Builders Federation.

Urban morphology as a discipline is uniquely skilled to analyze small-scale development patterns -- past and future -- but the issue of scale seems not yet to have caught the attention of a significant number of its members. This is somewhat ironic because small-scale development is

one of the most characteristic features of urbanism before the mid-1900s. Historically speaking, urbanism in which most projects are large (such as the current building activity in central Miami) is rare. The historic city developed in a piecemeal manner, mainly through investment by private individuals. In most cities this is still the case, but this fact tends to be overlooked by most professional associations and academia.

What would be the benefits of a research paradigm shift to small, other than consistency with actual conditions on the ground?

The preceding section's analysis of legal obstacles to small development helps us understand why a city would fail to develop its small lots and instead develop in a mostly large-scale fashion. The reason may surprise many readers: some small lots remain vacant not because the owners speculate on a windfall offer from a large-scale developer, but simply because a small-scale project would not be feasible due to the operation of one or more legal requirements.

Uncovering these hidden obstacles is a condition for policy change and an increase of small building construction, especially in areas that are not the focus of large development companies. The latter idea is essential, in that it moves beyond urban morphology's predominantly descriptive activities and into the territory of the normative. It is of crucial importance to study the relationship between the urban development processes and the socio-economic outcomes for the occupants of the resulting city. Even though the role of academia cannot be the making of generalized value-judgments, parts of its vocation might be the preparation of informed decisions by the wider public, politicians and professionals in a specific place and situation.

In the case of small-scale development and the resulting fine-grain urban neighborhoods, literature already exists documenting its advantages. The same day this paper was due, the National Trust for Historic Preservation's Green Lab published a report finding that urban neighborhoods characterized by small lots and buildings of different ages also have more people per acre, households per acre, residential units per acre, businesses per square foot, jobs per square foot, and percent of jobs in small businesses (National Trust for Historic Preservation, 2014).

Nassim Taleb writes that, while modern urbanism is "fragile", the urbanism of Jane Jacobs (dense but fine-grain and mixed-use) is "anti-fragile" and can actually improve with stress (2014); however, he also writes that, in the event of calamity, the most robust systems are made of many small parts that each have many uses (2010). Richard Reep makes a similar point about urban development post-2008: "People are turning local needs into opportunities at a scale that is small enough that outside help is not needed" (2012).

Continuing with the theme of small scale contributing to robustness, Joe Minicozzi finds that small (three- and four-story) mixed-use buildings generate outsize property tax per acre, meaning a city need not incentivize towers to balance its budget (Sonoran Institute, 2012). Eric Klineberg, a disaster recovery expert, writes that the best disaster recovery resource is social connectivity that is characteristic of neighborhoods that are dense but fine-grain (Klineberg, 2013), not composed of the skyscrapers that Richard Florida calls "vertical suburbs" (Florida, 2012).

Charles Montgomery's book *Happy City* about the many ways that urban design can improve human lives describes a surprising number of such improvements that depend on or are intensified by a fine-grain urban context (Montgomery, 2013).

More correlations should be studied to understand if and why small-scale development leads to urban environments that tend to be the most desirable and sustainable. Such insights can then guide policy and political decisions. Such studies would be particularly helpful if they focus on recent developments and avoid the distractions of "historic patina" and "charm". What matters is not that tourists on their Paris trip prefer the Marais to La Defense, but the fact that small-scale environments anywhere might be more robust, diverse and mixed-use.

Another potential benefit of small-scale development is its ability to involve more people in city-making. Buying a condo or renting an apartment is not the same as an individual designing, building, and owning his or her small building. Natalie Weinberger writes that small-scale

development can be a path to economic justice (2010), and William Apgar makes a similar point about ownership (2004).

The value of increased participation is difficult to dismiss in societies that proclaim democracy. If our built environment is seen as a mirror of our political system, such interpretation is not negligible. However, increased participation in a process may not result in improved outcomes, just as there is no agreement that Swiss direct democracy produces a better society than a more representative form of democracy.

Such a thesis regarding participation in urban development is difficult to prove, but that does not render the inquiry irrelevant. It fits well with the current Zeitgeist of “open-source” and “crowd-source”, and the perfection of that approach in computer programming (Raymond, 2000) now being tested in real estate “crowd-funding” by Fundrise and similar companies. This trend has already manifested itself in small development, for example the early-2000s rise of co-housing development in Germany. Such novelties are just the translation of changes happening outside the real-estate sector, including trends like 3D printing, customized fashion and individualized app-programming. In the coming decades we will witness the growth and creation of ever stronger conglomerates and monopolies, but on the other hand we will - and already did - see the emergence of a counter-reaction.

Urban morphology provides all the tools to analyze the workings of these promising developments and opportunities, and can help reveal the implementation issues that they face. Most importantly, it can also help identify the most promising development patterns, an exercise that historic studies do not have to provide. We believe that this could and should be one of the goals for the future of the conferences, the journal and the discipline in general.

Towards a flexible definition of limits in urban planning: controlling urban form under uncertainty

Bruno Moreira

Centro de Estudos de Arquitectura e Urbanismo, Faculdade de Arquitectura da Universidade do Porto. E-mail: bmoreira@arq.up.pt

Abstract. *Portuguese formal planning system was born in the thirties and has since then promoting the development of an opaque, centralized, hierarchical and ineffective planning system. In the seventies modern concepts of planning began to be applied, still limited to consolidated urban areas and surroundings. Reality was that the territory beyond those limits was growing without control, pushed by industrialization, increased mobility and people's expectations towards better conditions. When the first systematic plans that considered the municipality as a whole were born in 1982 and the shift towards a strategic planning approach gained importance in the nineties, the territory was complex and disordered. Plans and regulations created to limit and control the individual's increased capability to transform the territory became part of a reactive and prohibitive planning system instead of one based on pro-activity and responsibility: the inflexible nature of these plans led to delays in their definition and approval as a response to uncertainty. (Portas 1995). The concept of limit is structural and deeply embedded in plans and regulations, as it influences and controls urban form, which is gaining significant relevance within urban planning since the eighties (Oliveira 2006). Our goal, as part of a research focused on the flexibility of planning instruments and their efficacy on regulating contemporary urban space, is to identify how these limits have been understood in key moments of society and expressed in their plans and regulations.*

Key Words: Flexibility, limits, municipal planning, uncertainty, urban form

Introduction

Contemporary territories are changing at a fast pace. Concepts and methods to understand and regulate it are being questioned as they do not efficiently respond to these territories' needs, such as, precisely, the concept of *limit* – morphological, administrative, symbolic and disciplinary.

A flexible limit is, apparently, a paradox: by *limit* we use to think of a boundary that clearly separates one entity from another, a boundary that is stable and unchangeable, of entities that have their own autonomous logics and that don't overlap. This was clearly noticeable during the Modern Movement, when the *limit* was used as a rational tool to bring clarity and order to planning, mankind overcoming Nature throughout an unlimited rationality. Nature itself always had, however, its kinds of flexible limits.

With this article we intend to address one specific question: *How has the concept of limit been understood in key moments of the twentieth century in science, society and urban planning theory?*

With this article we intend to introduce how the concept of *limit*, applied to those topics, is changing towards openness, multidimensionality and flexibility, and why we must adopt it to be able to effectively control urban form under uncertainty and achieve better plans and regulations, providing an important theoretical framework for the broad research which is currently undergoing and that has as case study the municipality of Santo Tirso in Vale do Ave, Portugal.

The three topics that will be discussed in this article – “*Towards a limited rationality*”, “*Unlimited citizens and territories*” and “*The limit in controlling urban form*” – have their own autonomy, but they can also be read as a (simplified) macro-narrative, introducing how the shift towards a limited rationality and the increased ability for the citizens and cities to break their

own limits have brought uncertainty to the ability (and purpose) of controlling urban form in contemporary societies.

Towards a limited rationality

Contemporary urban planning is shifting from a rational-comprehensive approach towards a strategic approach. It is common to consider, on the one hand, the rational-comprehensive approach as a centralistic “top-down” approach where science and technical knowledge are used to determine the best solution for all planning issues, attending to a well defined public interest, and following a precise and linear process, while, on the other hand, strategic planning is considered a decentralized, multi-level and multi-directional approach where the discussion and the learning process between planners, policy makers and the citizens is as important as the scientific and technical knowledge, the planner assuming a mediating role between numerous public and private interests, and where the process is non-linear and subject to changes and uncertainties.

The seek for unlimited rationality in planning was evident on the “voluntaristic” and “planifying” urbanism of the sixties and seventies (Ascher 1991) but it was already present in several scientific fields and production modes which have influenced it – such as *Positivism*, *Taylorism* and *Fordism*.

The theory of *Positivism*, introduced by Comte and further refined by Durkheim in the late nineteenth century, argued that the natural science’s rationalism should also be adopted by social sciences. Reality was something that existed independently from the knowledge of those who were living it. The world should be objectively defined independently from our representation of it and social reality was conceived as divided between “normal” and “abnormal” states which needed to be “cured” (Durkheim 1982).

In the rational-comprehensive approach, the planner had indeed the role of defining urban development with maximum objectivity and independence from city life, deciding what was right and what “needed to be cured” on behalf of a well determined public interest, paying little attention to those who were living the reality (and thus were unable to see what was best for them). The design of the city was therefore scientifically based in zones, parameters, ratios and indexes (Busquets 1995).

In the beginning of the twentieth century, Taylor aimed to promote efficiency in scientific management, arguing that despite the extent of material inefficiency (such as natural resources depletion), human inefficiency was far a greater problem in need to be addressed. He then proposed *systematic management* as a rational system able to reduce every single action of the workmen to a science, replacing individual judgement with universal and systematic laws (Taylor 1919).

Traditional and empirical knowledge, passed from one generation of workers to another, was to be replaced by scientific knowledge gathered, filtered and disseminated by a new class of men – the *managers* – who should develop a science for each step of the productive process and train the workmen. This meant separating *planning* from *execution* in the belief that the subdivision of labor would increase productivity but also well-being of both workers and managers by balancing responsibilities, and that better management was the way to make workmen do their work better.

Planning ahead was a key component of Taylor’s theory and the specialty of these *managers*, who should anticipate *tasks*, means to achieve them and time to be spent, an effort to avoid the discretionary present in old management systems which allowed a great part of the learning and decisions to be led by the workmen. In the end, Taylor’s vision was of an organizational machine comprised by well defined and organized groups of individuals interacting with each other with clearly defined roles.

Taylor’s principles can be found in the rational-comprehensive approach in urban planning, namely in the planners’ position as *managers* of urbanity in the sole possession of scientific

laws, correct principles and adequate ratios and parameters. Planning believed and intended to anticipate all tasks of urban development, as if there was only one (scientifically) truth, only reachable by planners with their technical expertise, thus reducing any sort of judgement from those who executed – and lived with – the plans.

As of *Fordism*, it emerged as a paradigm for the innovations in the work processe, capital accumulation and social regulation established in the capitalist society around 1920 (Jessop 1992). Mass production of standardized goods was achieved through the division of labour in the assembly line (and in the territory), increasing their affordability and profitability by means of an economy of scale, producing standard goods for an anonymous and homogeneous public and making them available through mass retailing and desirable through mass media; accumulation was possible throughout a repeating cycle of mass production and mass consumption, driven by the continuously rising cycle of productivity, demand, profits and re-investment; but Fordism was also to be found in the social regulation present in the set of norms, institutions, networks and patterns of conduct that guided the capitalist society (Jessop 1992). Planning focused in the production of plans, rather than on the production of urbanity, through hierarchical and institutional assembly lines that produced plans for an anonymous and homogeneous society and on behalf of a centrally defined public interest.

The post-war economic boom was driven by these paradigms, which were reflected in the new practices on work management, mass production and consumerism as allowed by technological assembly lines and economies of scale (Moreira 2004). Rationality was the answer to the city problems as a whole, aiming to replace the old and degraded (or destroyed) cities by racional, homogeneous and functional new ones (Busquets 1995). The Modern Movement played an important role on bringing rationality to the planning system: the plan as a technical document designed by specialists and enforced by a strong central state (Soares 2000) finding in it the instrument of its own legitimacy (Veneza 1998). Fordist cities were created, combining modern architecture and urbanism with *neo-keynesian* urban policies (Ascher 1991).

Keynes' vision was of an economy that should incorporate the concept of uncertainty, instead of being obsessed with predicting the future – therefore distancing itself for the seek of ultimate rationality as Positivism, Taylorism and Fordism did. For Keynes, the economic theory should be a method and not a doctrine (Olivares 2009) and its models should be used as instruments of thought and not as quantitative formulas (Hodgson 2011). Keynes attacked the traditional concepts of economy who believed that unemployment was a self-regulated system, stating that it depended (as well a consumerism) on the amount of investment – which, in turn, was extremely volatile due to the uncertainties towards the future (Hodgson 2011). The way was open for centralistic and (still) powerful national states to legitimately enforce extensive public interventions on behalf of a supposedly public's interest, reflecting the rational distributive nature of the public welfare state policies that tried to balance the access to goods and services (Ascher 1991; Moreira 2004), distributing public investment to more recessed areas (Marques 1995) and leading to a decentralization of equipments and production activities in an attempt to balance urbanity.

Again, an homogeneous vision of reality was present in the minds of politics and planners and in the mainstream economy and other fields of knowledge, obsessed with rationality and with the intention to predict the future with the help of technocratic, mathematical and formalist models, stepping back from the uncertainty concept that was fundamental in Keynes theory (Hodgson 2011) and that is gaining increased relevance in contemporary society.

Contemporary thought on urban planning is distancing itself from this kind of absolute rationality towards a more limited one due to several failures in previous paradigms. Fordism has failed as a virtuous cycle of permanent growth – making companies think on switching from stocking large quantities of standardized assets towards a “just-in-time” strategy (Ascher 1991) and from producing homogeneous standardized goods to producing good with some sort of customization – and as a rational approach to urban development, which has led to mono functionality, segregation, crime and dispersion of residential zones. Collective and public transport policies are challenged by the needs of contemporary society, which demands more

flexible means of transportation, especially in dispersed territories, leading to the rise of the private transport (Soares 2005). The welfare state is facing serious problems as well as the Keynesian politics which are suffering from the vicious cycle of “stagflation”, i.e. high unemployment and inflation and low growth (Jessop 1992).

The planning efforts that tried to accommodate and control reality as a whole are now inefficient due to their normative and rigid nature when faced with new, complex and fragmentary urban forms and political, social and economic dynamics (Venezia 1998), being now understood as obstacles to decisions that must be made quickly in order to grab opportunities (Marques 1995) *just in time*. Planning needs a broader project for the city, able to articulate several scales and actors in its development.

After this “rationalizing” and “voluntarist” phase, we are facing, since the eighties, a “liberal” and “concurrential” urbanism where rational models are losing ground to incrementalist and heuristic methods on urban development (Ascher 1991). Urban planning is shifting from the rational-comprehensive approach towards strategic planning, or from an absolute towards a limited rationality. The solution for the future cities is neither in chaos, nor in global solutions, and there’s no unique key to explain all current urban forms (Borja et al 2003).

The concept of strategy is now deeply present in urbanism: the city is no longer planned as a whole, but with precise interventions which try to grab or create opportunities. Instead of rationalized “truths” about the territory and its development, the focus is now on defining long-term objectives and ideas on the city, finding the available options to make them possible and creating urban management mechanisms able to make that strategies operational (Ascher 1991). Strategy, and its integration of deliberative, responsive and shared participation mechanisms, is also found to be a way to develop urban proposals with enough legitimacy and social support (Borja et al 2003) in a time where social life is fragmented and national political power diminished, thus making it difficult to determine and give unique answers to societies’ needs.

Unlimited citizens and territories

Contemporary citizens are increasingly complex in their needs and aspirations and in the tools they have to achieve them. The association between new, faster and more reliable ways of transport and communication has increased mobility and communication possibilities and the ability for these citizens to respond to needs and aspirations that would otherwise be harder to fulfill. This has been leading to new ways of interacting with others, giving rise to more heterogeneous social groups and family models and to more numerous and diverse – though less stable – social relationships (Borja et al 2003).

Still, in an apparent paradox, these *unlimited citizens*, powered by all these means of transport and communication often isolate themselves. The increased mobility and access to information and communication technologies, although can play an important role in promoting citizenship by making easier the relations between citizens and administrations, and by connection global with local identities (Borja et al 2003), may also increase segregation for some sectors of society (Domingues, & Silva 2004) as economic capital and knowledge restricts the ability to move and connect. Gated communities, in suburban areas, linked to an “hiperspaced” mobility, show how some of these citizens do fear the “real city” (Muxí 2003). However, their spatial segregation is different from that of the Modern Movement, where rationality was involved in determining spatial distance between different social groups; in the contemporary city the space is fragmented and diverse, personal and work relationships have no fixed territory (Carreiras 2013): a gated community can coexist side by side with social housing and / or with a highway. Social cohesion and citizenship coexists with urban and social fragmentation (Borja et al 2003).

This complexity leads to the difficulty in representing the society as a whole and mediate or make compatible everyone’s interests. Political power still fails to recognize this plurality,

dedicating speeches to the *public* or the *people's* interests because they represent an ideal of *limited* society that is not accepted anymore but that is still the main target of the political power. Public interest is hard to be defined. Due to this increasing complexity, citizens in contemporary world are increasingly harder to be represented. There isn't a single territory of proximity but multiple belongings and identities, and citizenship should not be limited to the scope of an individual "state" (Borja et al 2003). Belonging is no longer funded in proximity or on densities, as transports and communication technologies made us part of numerous and diverse relationships (Choay 1999). Contemporary citizens have progressively more numerous and diverse interests and values, which translates into more complex and varied actions throughout the territory, giving way to new ways to explore and inhabit it (Domingues, & Silva 2004) and to a new kind of citizenship.

Citizenship is deeply related and embedded in the concepts of city and public space, which tend to confuse themselves and have multiple meanings (Borja et al 2003). Dispersion, fragmentation and privatization are considered to be the three key processes which are making public space disappear as a citizenship space (Borja et al 2003). In the "Third City", there is (often) a lack of an "urban landscape of citizenship" (Borja et al 2003). The Generic City produces dispersed pieces throughout the territory in a "functional urbanism" for private business among politics and architects, but it does not produce citizenship (Borja et al 2003). These unlimited citizens are making the territory harder to be limited as well.

Increased mobility has deeply changed and reduced the *limits* of the territory for those who were able to pay the price of mobility. Cities have expanded their well defined and fixed limits towards suburban growth, invading rural land. A new reality has emerged where those expanded city limits have clashed, confused and mixed themselves, ultimately making their limits disappear – such as the limits between those two main containers where we still insist on fitting all reality: urban and rural land.

Urbanity has ceased to be an exclusive feature of the city (Domingues 2013) and its limits are increasingly hard to trace if we intend to do it against a "rurality" that no longer matches its archetype and has no substantial social and cultural difference from the city (Soares 2005); the construction of urbanity has also ceased to be the exclusive competence of the public sector, weakened in its ability to intervene, to be opened to partnerships with the private sector, to the international capital and to a strategic and entrepreneurial management (Moreira 2004) considered more effective for its flexibility, adaptability to opportunities and to uncertainties, but still in need of democratic control and transparency (Borja et al 2003).

Both territory's and citizens' limits are becoming hard to define: there are multiple types of limits at a given time, overlapped and diffuse. Multiple limits coexist on our cities: traditional limits, industrial limits, relational limits, symbolic limits, all present at the same time in our imaginary. Delimiting this territory is an task requiring innovation – these *real* limits do not correspond and are questioning *administrative* and *political* ones, which do not correspond anymore to the complex dynamics of economy and society (Ferrão 2014).

This leads us to the last topic of this article: after stating that an absolute rationality is no longer an answer for the knowledge of the city, and that its knowledge is increasingly harder to gather due to the fragmentary nature of the citizens and their ways of living – how can urban form be controlled under this context of uncertainty?

The limit in controlling urban form

The changes in the strategies of urban planning and management can't be understood unless in relation with the changes in its social and economic contexts. The major transformations on the european societies of the twentieth century have generated, besides multiple distinct urban forms, different positions on how to plan and manage the territory.

Urban planning was legitimized by means of the Athens Charter, place where the CIAM Congress of 1933 was organized, as a rationalizing instrument used by a welfare state in its full

capacity, able to promote large urban operations integrating, simultaneously, “networks”, built “volumes” and “green” or “free” spaces (Portas 2005). From the post-war to the seventies, society grew in a fast pace motivated by the Fordist machine of mass production and consume, at the same time that the welfare state reinforced its rational and distributive planning actions on the territory.

This state, true to technique and to its notion of public interest, distributed public equipments and productive and industrial activities into *zones* according to technical and scientific criteria, assuming itself as the main agent of the territory’s transformation – but the Fordist model started to decay, the mass production and consumption cycle started to wear out, and this state’s capability to transform and control urban form became weak. Influenced by neo-liberal politics, it had no choice but to share its power with the private sector throughout partnerships, and to bet on more targeted interventions – losing its monopoly on controlling the territory, abandoning its role on designing urban form except for the infra-structures, unable to cope with the increased number and power of agents able to act on the territory (Portas 2005).

From the eighties, we are witnessing the globalization and internationalization of economy and the reticular recomposition of the territory. The tertiary is gaining more relevance and the rigid Fordist production models more flexibility, betting on innovation in order to adapt to the needs of a complex and differentiated society demanding, simultaneously, mass production and customization. It’s in this context that strategic planning is gaining importance, trying to make more operational the actions on the territory, seeking complementarity relations between cities and the engagement of all actors with enough power to intervene in the territory, reviewing and integrating alternatives in the planning process, and progressively paying more attention to context and contextual solutions (Domingues, & Silva 2004). Regions are inherently different in their built environment, population, lifestyles – not “blank sheets” (Ferrão 2014).

This increased localism seeks also the participation of a greater number and diversity of actors in planning (Alves 2008) and is a reflex of the globalization that reduced the power and functions of the central states, weakened their representativeness, and promoted a greater distribution of power throughout the territory and more noticeable actions from local and regional economic, social, cultural and administrative agents (Ferreira 2005). The national states are losing their power in controlling urban form towards both local or regional powers, but also to supra-national organizations such as the European Union.

This same role of events was present in Portugal, with the adoption of Duarte Pacheco’s detailed and rational urban plans in the forties, which intended to predict the city transformation in long term (Carvalho 2004) but quickly became misfit to reality; then, in the sixties, with the state seeking to involve privates in urban developments and replacing urban design by zoning and quantitative parameters.

The unpredictability of opportunities and execution capabilities, the need to opt for cooperative solutions over “rationalized” unilateral ones, and the need to more responsively involve the increasing number of agents with the power and will to transform the city would lead to the strategic model in urban planning (Carvalho 2004) and to substantial changes in understanding the city and the urbanized territory, particularly from the eighties (Domingues, & Silva 2004). This connection between planning, evaluation and reflexive management of the territory with a strong local component is essential to the uncertainties of a society where reaction is sometimes as important as planned action.

Planning and urban management must be intimately related and permanently informed by processes of self-evaluation in order to be able to change, if necessary, and to define new goals and objectives (Encarnação 2011). Only through a systematic evaluation can planning be assessed in terms of its efficacy and credibility (Oliveira 2011) and adequately respond to the specific problems of urbanity – hence the importance of the concept of reflexivity, in which every action needs a reflection for its adequate response (Ascher 2010). Planning systems must be flexible enough to adapt to these needs, both in their *formal* and *informal* instruments.

Portuguese planning system is formalized by a set of legal documents that establish power relations. These documents – plans, laws, decretes, regulations, etc. – create a network of

relationships that becomes an *apparatus* that act as a link between the state, its citizens and their multiple organizations.

The *formal apparatus* is an instrument of control of the urban form, understood not as an hostile device but as expected and legitimated by the society and democracy. However, due to the rising complexity and specialization of contemporary society, and of the entities of the state itself, these formal *apparatus* are often understood in contradictory ways, raising conflicts and deadlocks. The concept of state, as clarified by Bourdieu, is therefore fundamental to understand this logic of control: the state is a collective construct which derives from the historical accumulation of capitals of diverse nature – military, economic, cultural, symbolic – making it able to use its influence in all these fields in a way unsurpassed by any other group or social agent, having, in exclusive, the ability to create the laws and punish the offenders: the “monopoly of legitimate physical violence” (Bourdieu 2001).

The formal *apparatus* assumes itself as a particular expression of this “legitimate physical violence”, carried out by a state legitimized by its citizens, with the particular purpose of regulating the transformation of the physical and spatial environment of the city but also the social relations of the agents responsible for such transformations. Implicit here are the two dimensions of these formal *apparatus* that we consider fundamental to their understanding: the *apparatus as an object*, embodied in the writings and documents that give the its material support; and the *apparatus as a process*, reflected in the institutional relations between social agents whose power directly depends on their ability to interpret and manipulate those *apparatus*.

The complexity of these *apparatus* as objects is clear since they are many and relate to each other in complex ways. In the current framework of the Territorial Management Instruments, these *apparatus* are distributed by national, regional and municipal levels, according to a hierarchical logic; we find *apparatus* of strategic nature (such as the PNPOT, the PROTs, and the PIOTs), of regulatory nature (such as the PDMs, PUs and PPs) and of special or sectorial nature, such as the specific plans for key areas of administration – such as transports, communications or energy.

All these types of plans establish between themselves complex networks of relations that influence behaviors and processes, affecting the ways to understand the logic of planning itself. Some authors point out the difficulties in understanding the role of these plans as defined in theory and consequentially their wrong use in practice, such as using the PDMs as rigid and normative plans instead of regulation tools (Encarnação 2011) or the excessive formalization and binding nature of the PPs and its misuse (by ignorance of the role of the PUs) as a way to change plans of a higher order (Sá 2002).

We thus realize that these *apparatus* as objects are not likely to be fully understood without their use and transmission by the agents and social groups that deal with them. However, their material transmission (which is becoming increasingly facilitated with ICT) must not be confused with their real understanding and incorporation, which requires time, as Bourdieu remembers us (Bourdieu 1979). To use them without interpretation or critique is to forget the complexity and uncertainty that defines contemporary society, rendering the *apparatus* useless.

The limitations and lack of flexibility of these *formal apparatus* make for more *informal* actions to occur within urban planning processes, as a response to the inefficiency and inflexibility of the former, both as objects and as processes, although some authors accuse this inefficiency to be associated more with the latter – such as the mechanisms involved in planning revisions – than with the material content of those plans (Sá 2002). The difficulty comes from the fact that changing the formal object may also mean changing a previously established power relationship. The plan is therefore involved in a struggle between several entities that try to control it according to their skills and interests.

We may as well note that the struggles around the formal *apparatus* are not simply struggles between a state and its citizens: state and citizens are increasingly complex entities formed by agents and social groups of different natures, resistant to such broad simplification; the state multiplies itself by several entities, and the same happens with contemporary citizens, with their

multiple belongings, interests and aspirations, continuously adapting themselves to more and new challenges in the contemporary society. In the growing impossibility of predicting the future, it becomes increasingly important for formal plans to learn to act in a more strategic and less deterministic way on defining urban form. The formal plan, both as an object and as a process, must therefore seek to be the structure of human action and not the prediction of the action itself, assuming uncertainty as an integral part of human nature which gives the foundation to the “plurality of world views” (Bourdieu 1989).

It's in this context that the informal *apparatus* moves: as a flexible structure and not as a set of rigid rules. The use of these *apparatus* has become widespread due to the inability of the formal plans to solve, in due time, the problems of the territory, with the entities responsible for its control using other sorts of plans such as details, plans of city blocks, of heights and alignments, of axis, to name a few (Portas 1998). They assume themselves as plans of no legal validity, but they allow for more open negotiations with individuals, the creation of more and faster alternative scenarios with a strong visual component, therefore being more effective on reconciling the diverse interests and positions of the agents involved. Their content is not determined *a priori*, but according to a set of events and developments and according to the particular objectives of each situation. Informality is thus present both in the more diffuse power relation between those agents, and in the un(pre)defined nature of the informal *apparatus*, allowing for more flexibility and proximity during the discussions.

Conclusion and further work

This article intended to provide a theoretical framework on the concept of *limit*, discussed in the three topics that we've covered: “Towards a limited rationality”, “Unlimited citizens and territories” and “The limit in controlling urban form”.

In “Towards a limited rationality” we've focused on the limits of the rational-comprehensive approach in planning in relation to the unlimited conception of science and knowledge, expressed in several paradigm such as *Positivism*, *Taylorism*, *Fordism* and *Taylorism*. As those paradigms failed, a new way of planning has risen, adopting *uncertainty* and a *limited rationality* as a way to better address the new contemporary challenges of urbanity.

“Unlimited citizens and territories” showed us how both territory and citizens *limits* have changed, became more complex, diverse and multiple, influencing one another in the production of space and citizenship. Globalization, internationalization of economy, development of better transports and communication systems are enabling us to extend and dissolve *limits*, making them more complex.

Finally, “The limit in controlling urban form” intended to show us how these diffuse limits and their expressions in the territory are making it difficult for planning to understand and accommodate all urban forms and dynamics that they have created, forcing it to bet not on over-rationalized and homogeneous solutions – or rational intentions to balance urbanity – but on diverse, complementary and cooperative solutions to make urbanity and its unequal parts work better together, which sometimes means taking advantage of unpredicted – and unpredictable – opportunities.

Understanding the contemporary limits in controlling urban form requires, therefore, understanding the complex context of our unlimited society and territory and how they relate to a particular philosophical position concerning science and knowledge.

The concept of *limit* is also being questioned in other topics that extend or complement the topics that were brought to this article, such as the *limit* between *urban* and *rural land*, *center* and *periphery*, *public* and *private* developments, *formal* and *informal* planning, the *limits* on the representation and communication of the territory, of *Supra-National*, *National*, *Regional* and *Local* powers, the *limits* in the increasingly *multidisciplinary* knowledge on the city, etc.; all these *limits* are becoming diffuse and confused, questioning the role and efficiency of urban planning; but still we argue that understanding this new reality where pure black and white is

being replaced with multiple shades of gray is fundamental for urban planning to be more effective and able to deal with uncertainties and opportunities.

This article is part of an on-going research, and field work concerning the impact of these *limits* in the territory and in urban plans is currently under development on the municipality of Santo Tirso, in the Ave valley, Portugal.

Interpretation of morphological data to inform design. *Bridge to Bridge: Ridge to Ridge* urban design workshop

Paul Sanders

School of Design, Queensland University of Technology.

E-mail: ps.sanders@qut.edu.au

Abstract. *The importance of design practice informed by urban morphology has led to intensification in interest, signalled by the formation of the ISUF Research and Practice Task Force, and voiced through several recent academic publications²⁶². Cognisant of this current debate, this paper reports on a recent urban design workshop at which urban morphology was set as one of the key themes. Initially planned to be programmed as a augmented concurrent event to the 2013 20th ISUF Conference held in Brisbane, the two day Bride to Bridge: Ridge to Ridge urban design workshop nevertheless took place the following month, and involved over one hundred design professionals and academics. The workshop sought to develop several key urban design principles and recommendations addressing a major government development proposal sited in the most important heritage precinct of the city. The paper will focus specifically on one of the nine groups, in which the design proposal was purposefully guided by morphological input. The discussion will examine the design outcomes, shedding critical light on the issues that arise from such a design approach.*

Key Words: urban morphology; urban design; design workshop

Discussion

Context

This papers reports on the outcomes of a major urban design workshop held in Brisbane, Australia, that occurred over two days in August 2013. The workshop involved over one hundred participants, with representation from the design professions and academic disciplines. Of particular interest is the inclusion of urban morphology as a key theme in the agenda of the event, and the paper will assesses how the theme manifest in the design strategies of the working groups.

‘ISUF aims to bridge the divide between academic and applied. It seeks to advance research and practice’ (Whitehand, 2012).

The paper responds to the call from the ISUF Task Force on Research and Practice for examples of research-led practice (Samuels, 2013), and provides a case study in which the design leadership of one particular workshop group was jointly led by an academic (the author) and a leading urban design professional.

The Bride to Bridge: Ridge to Ridge urban design workshop (B2B UDW) was organised in reaction to the release of information concerning a proposed development which put an important heritage precinct under threat. Ever since the initial consolidation of the urban form of Brisbane in the later part of the nineteenth century, the focus area has been severely impacted by major large-scale developments; and furthermore several controversial development proposals have increased awareness of the fragility of the heritage precinct, warranting action by professional bodies and academic institutions.

Research & Practice

The significance of urban morphological study has yet to be broadly recognised amongst urbanists; it however occupies an intriguing position at the confluence of current contemplations on how the urban form of cities should be managed, providing a basis for a cross-disciplinary search for relevant urban design methods.

Jeremy Whitehand has for some time now, identified the failure of urban design to draw on urban morphology (Evans, 2005); he nevertheless surmises that 'there has been increasing interest beyond academe, in mapping the 'character' of areas and this interest must surely lead, sooner or later, to strengthening the bridge between urban morphology and urban design (Whitehand, 2005, p3). He posits the justification for urban morphology as having practical utility and intellectual value, while recognising that the townscape has an aesthetic value (Whitehand, 1987, p2). Furthermore the understanding that the 'historical unfolding of the built environment is the starting point in the search for a theoretical basis for the management of urban landscapes in the future' (Whitehand, 1992, p6).

Certainly intensification in this discussion has led to a number of published articles in recent volumes of *Urban Morphology*, see 17(1) and 17(2); as well as a special edition of *Built Environment* journal dedicated to article addressing the theme of 'Urban Morphology and Design' (Marshall and Caliskan, 2011).

ISUF Manifesto – Research & Practice Task Force

'Urban morphology promises to bridge a gap which is currently debilitating both the research and practice of city building' (Moudon, 1997, p8).

The escalation of interest into the question of how research can inform practice? has prompted ISUF to establish a Task Force in 2012, to better bridge between researchers in urban morphology and urban design practitioners, and to draw up a report with concrete suggestions for action (Samuels, 2013).

There are two key interconnected intentions of the draft proposal of the Task Force, they are: to increase the influence of urban morphology by better packaging and marketing, and secondly; raise the level of understanding and application of urban morphology in a range of relevant professions through the channel of education and professional organisations (Samuels, 2013).

Furthermore it is suggested that urban morphology, 'as the science of urban form' (Samuels, 2013, p42), can benefit a range of different sectors, for example: those of whom are concerned with describing and analysing urban form, environmental design professionals, and importantly the clients and employers of both these groups (public authorities and developers).

Arising from this overview four recommendations are made in the preliminary Task Force report:

- the publication of a manifesto;
- the compilation and publication of relevant curricula in different countries;
- the production of a good practice guide, and;
- the creation of an urban morphology toolkit for understanding the past and planning; the future of urban settlements. (Samuels, 2013).

The author's own recent 'viewpoint' in *Urban Morphology* on this issue drew attention to the tension between prescriptive controls for design, versus a more open process of interpretation of research material in design practice (Sanders, 2013). The case study example of Workshop Group 4, from the B2B UDW was led by the author and a leading urban design professional, and will offer a glimpse to how the provision of morphological data can influence the design process.

Brisbane and its river – a brief economic and morphological overview

Brisbane is situated on latitude 27° 28' South, in a sub-tropical climatic region approximately 750 km due north of Sydney.

The first inhabitants and traditional owners of the Brisbane River area are the Aboriginal groups of the Turrbal, and Jagara people (Greenop and Memmott, 2007). Their place values and place-making activities, being points of orientation for spiritual, social and cultural reference and including sites of large gatherings (Greenop and Memmott, 2007), were numerous and widespread throughout the region.

Figure 1. Early surveys of Brisbane River. 1a: Oxley, J (1823) Section from *Plan of River Brisbane and chart of Moreton Bay* (source: National Library of Australia). 1b: Dixon, R (1839) Section from *Plan of Brisbane River and Moreton Bay* (source: State Library of Queensland).

European occupation followed John Oxley's discovery and survey in 1823 of a large tidal river suitable for settlement (Johnson, 1988, 12; Johnson, 1989b). A convict colony, initially known as Moreton Bay Settlement (Johnson, 1989b, 242) was established in 1826 on the banks of the river, some 16 km upstream from the sheltered Moreton Bay; and housed only the hardest of criminals from the penal colony in Sydney.

The initial convict settlement comprised a small number of buildings, the first of which was the Commissariat Officers Quarters, which was a timber cottage that had been relocated from Sydney, and re-assembled in 1826. This was followed soon after by the construction of a Convict Hospital, and establishment of a Timber Lumber Yard in 1827; Prisoners Barracks and Chaplain's quarters in 1828; and Observatory, Windmill and Commissariat Store in 1829 (BrisbaneHistory.com). The latter two are the only remaining structures from this period that have remained; the Commissariat Store located alongside King's Jetty (later renamed Queens Jetty after the accession of Queen Victoria), which was the original place for ships to dock; and the centre of the present day heritage area.

The penal settlement was short-lived and was closed in 1839. Transportation of convicts ceased in 1841, with the official proclamation that ended the penal colony declared shortly after in 1842 (Gough and Ogilvie, 1985; Johnson, 1988; Johnson, 1989a).

Even during the period when the convict settlement was being dis-established, preparations for free-settlement were already well underway. The period of economic development in the new free settlement was initiated in 1841 by free traders and tradesmen who had established shops through leasing space in the former convict premises; this was soon followed by the first sale of land in 1842, by auction in Sydney for £100 per acre (Johnson, 1989a, p261; Gough and Ogilvie, 1985; Johnson, 1988).

The new town experienced a steady growth during its formative decades, with commercial and trading businesses emerging concurrently as the migrant population increased. The first census in 1846 showed that there were 960 people living in Brisbane, and 2258 people spread

across the region; by the 1851 census Brisbane's population had increased to 8375 (Gough and Ogilvie, 1985, p8; Johnson, 1989a, p106).

Figure 3. Looking towards William Street from the Brisbane River, 1865. The Commissariat Store and Kings Wharf is to the lower right; Kings Wharf Road leading uphill from right to left. (source. State Library of Queensland).

It was not until 1867 that the settlement underwent its first economic boom following the discovery of gold by James Nash at Gympie, some 170 km north of Brisbane. The huge influx of people that followed triggered an unprecedented growth in primary industries, and a period of prosperity and building activity that would last 15 years, and would not be equalled for a century. It was eventually ended by the cutting out of the gold and the world financial crisis of the early 1890s (Holthouse, 1982, p41).

Brisbane had become a significant shipping port with minerals, rural products and sugar as its primary exports. It was the capital of the annexed state of Queensland, and was to be proclaimed a city in 1902. The population of greater Brisbane at the time of the 1901 census was 119,428 people. The period of economic growth continued up to the advent of World War I (Statistics, 2009).

Figure 4. Carson, W.A. (1888) Part section of Balloon eye oblique 'View over Brisbane 1888' (source: Queensland State Archives).

From 1918, Queensland's economic base continued to be mainly foreign trade to the UK (73% of total exports); primary goods being wool (41%), butter (19.5%) and meat products (24.5%). However the impact of this trade was tempered by problems driven by increasingly higher prices for basic goods such as food and clothing.

To accommodate this growth in mercantile trade, wharves lined both sides of the Brisbane River allowing for large-scale docking capacity for ships. Neighbouring the wharves, and imbuing the commercial character of the city were numerous warehouses buildings, which incorporated the storage and office functions of the trading companies who were occupying the buildings.

Figure 5. *Sketch of the Brisbane River looking towards the wharf and buildings on Short Street, Brisbane, ca. 1889. The roofs of the Parliament House are visible on the skyline.*
(source: State Library of Queensland).

In 1925, the City of Brisbane Act (1924) came into effect, rationalising civic government by amalgamating 18 former local government areas under a single administration, the Brisbane City Council (Holthouse, 1982, 55). Despite strengthening Brisbane as an economically powerful civic entity, the impact of the Wall Street Crash of 1929 brought about the Great Depression in Australia during the early 1930s. Nevertheless by 1935 Queensland emerged with employment levels restored, stimulated from public works expenditure and the recovery of wool, wheat and metal prices to pre-depression levels (Statistics, 2009). Optimism was short-lived however, due to the onset of World War II which once again stifled economic growth and development in the city.

The post-war decades from 1944 found Brisbane dilapidated and neglected, and it was to recover much more slowly than either Sydney or Melbourne. However in the 1960s, with new mineral discoveries in Queensland, the city finally entered an enduring phase of prosperity from which Brisbane emerged as a modern city through a program of large-scale urban and civil construction, which has been sustained until the present day.

In summary, there have been two significant economic periods in Brisbane's 170-year-old history which have generated two distinct morphological periods of urban development in shaping the form of the city. These are approximately its initial growth from 1840s up to 1914; and then, following fifty years of relative fallow activity, a rapid growth from the 1960s to the present day.

Major urban disfigurements to the Northbank edge of the Brisbane River

Riverside Expressway 1968- 75

A Brisbane Transportation Study was conducted in the mid 1960s, which included recommendations for a number of major road improvements to address increasing traffic

congestion in the city. The Riverside Expressway was a key component of the plan, extending the Pacific Motorway from south of the city, over a new bridge, and extending along the entirety of the Northbank disbursing traffic into and from the CBD, via a complex configuration of ramps (Cole, 1984).

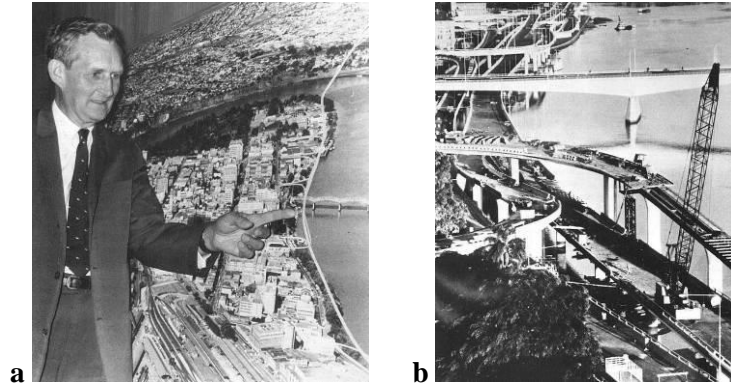

Figure 6. Riverside Expressway traversing the rivers edge. 6a: Wilbur Smith, in 1968 demonstrating the line of the proposed Riverside Expressway, a main feature of the Brisbane Transportation Study. 6b: Construction of the Riverside Expressway nearing completion in 1974. (source: Cole, 1984).

Large-scale demolition was required to enable the new embankment structure to traverse the river edge, and penetrate through fronting built fabric to connect to the existing road grid. In particular the quay and wharf profile was obliterated, replaced with multiple pylons supporting the road platforms; as well as an under-ramp car park that truncated pedestrian connection to the river at ground level (See Figure 7).

The obliteration of the small-scaled quay and wharf typologies occurred with the construction of the Riverside Expressway between 1968-74, and its presence has remained unaltered to the present.

Figure 7. Map depicting the alignment of the Riverside Expressway, and the outline of the river edge profile it replaced. (source: Queensland State Archives).

Queensland Government precinct- construction 1983-87

The Skidmore Owings & Merrill master plan for the State Government Precinct developed in 1976, was to be one of the largest State Government works to be undertaken spanning administrative office spaces across five city block sites (Massey, 2014). It is to be noted that in this proposal all existing heritage buildings on these sites were to be erased to make way for this development.

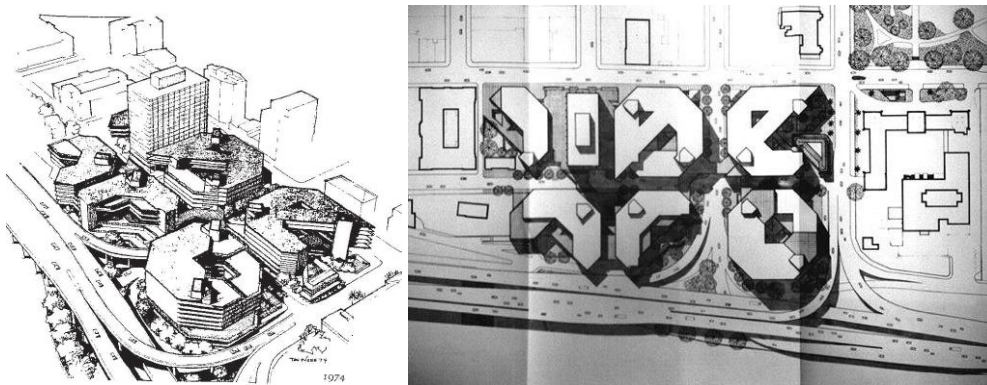

Figure 8. Preliminary sketches of the proposed SOM Masterplan 1976 for the Government Precinct. (source: Massey, 2014).

A reduced scope of building construction was eventually carried out by local architects Lund Hutton Newell Ryan Morton, and building works were completed in 1987 (De Gruchy, 1988). The complex accommodating the Department of Public Works in the new State Works Centre extended across the two sites along George Street and bridged over Margaret Street. Harris Terrace (ca1866) and The Mansions (ca 1889) were both spared and incorporated into the revised design; however the Bellevue Hotel (1886 – Figure 9), an elegant three storey building with cast iron balustrades and full length verandas, was unscrupulously demolished in 1979 under instruction from the State Premier, to make way for the new development.

Figure 9. Bellevue Hotel in 1940. (source: State Library of Queensland).

The controversial loss of the Bellevue Hotel (Follent, 2013) remains an infamous event in the history of Brisbane's development, in that it symbolises the crude and unsophisticated approach to urban growth at that time, an approach that lacked interest in the morphological and architectural significance of many historical areas of the city. Indicative of this attitude is the award of 'Joint Best Building' by the RAIA (QLD) in 1987 to The Government Precinct Building Block 1! (De Gruchy, 1988).

Northbank development proposal – 2008

In 2008, a Queensland Government supported proposal for the 'Northbank' ensured that the historic precinct came under further scrutiny with the release of details to reclaim land into the river to create a new high rise commercial development. The proposal would effectively construe a wall separating the river from its historic relationship to the city, cutting Brisbane off from its past (Robinson, 2007).

Stewart Armstrong, Director of the National Trust warned, "The history still exists, but the

ability to interpret the history and to tell the story of Brisbane will be greatly diminished" (Moore, 2007). Following considerable public outcry, the development proposal was dropped.

Figure 10. Northbank proposal 2007 (source: Brisbane Times).

Queen's Wharf- Government precinct proposal Brisbane – 2013

Most recently in 2013, a new government-led proposal for an 'Integrated Resort Development' was released, this time seeking to develop on the state owned land between George and William Streets; and also including the heritage precinct towards the river. The development is planned to expand the CBD including a mix of new uses such as: six star hotels, casino, retail, restaurant and entertainment zones, theatre and convention facilities and new open spaces.

With the renewed weight of development demand on the heritage precinct; and cognisant of the Queensland Government's record of sponsoring belligerent development, a number of concerned built environment professionals rallied to initiate a design workshop. The aim of the workshop was to give a platform for a collective voice from the design community, with the ambition to influence the trajectory of the State's decision making.

Bridge to Bridge: Ridge to Ridge urban design workshop – 2013

A call was made in July 2013 for participation in an urban design workshop focusing on the significant heritage precinct extending between the Goodwill and Victoria Bridges, and the Brisbane River to George Street: between the bridges, and from the ridge to the river.

Significantly the principal stakeholder groups involved were from practice, industry and academia. The professions were represented by: The Australian Institute of Architects and The Urban Design Alliance of Queensland; while The Brisbane Development Association represented the interests of industry. The three major academic institutions in South East Queensland are: Griffith University, Queensland University of Technology and The University of Queensland; a number of academics and students from their departments of architecture and urban design were also invited to participate in the event.

The organisers of the workshop represented both practice and the academy; Caroline Stalker and John Loneragan are both directors of architecture and urban design practices, while Leigh Shutter is an Associate Professor.

The expectation of the conveners for the workshop, were set out in the invitation flyer with the intention to develop the key urban design principles for the public realm of the precinct, forming the basis of recommendations to be sent to the State Government. The preamble and introduction to the workshop expanded on these general ambitions, articulating eleven specific themes; it is important to note that urban morphology is the third listed.

Design groups were encouraged to take consideration of:

- 1) The precinct's place in the city and connections beyond;
- 2) A network of public spaces;

- 3) Urban morphology;
- 4) Connections to the river;
- 5) Places of significance;
- 6) Traffic and transport (including the river);
- 7) Pedestrians and cyclists;
- 8) Flood mitigation;
- 9) Subtropical landscape;
- 10) Functions and activities in the public realm;
- 11) The experiences of the place. (Stalker et al., 2013).

The prominence of Urban Morphology as a theme can be attributed to the productive partnership that occurred in the programming of the ISUF 2013 Brisbane conference, with the annual Urban Design Alliance Superforum. The two events overlapped with a keynote session and cocktail function. Through this arrangement urban morphology was prominent in many discussions, and several design practitioners registered for the full ISUF conference. Furthermore Brisbane's earliest surviving structure, The Commissariat Store, was poignantly chosen as the venue to host the workshop.

Participants of the workshop were allocated into nine groups that were deliberately organized with a disciplinary mix; as well as a distribution of practitioners, academics and students. Groups were prompted by the conveners to consider several important questions, those with a morphological provocation were: What are the qualities of place that are important? What are the places that contribute most positively to the public realm? How does it fit and contribute as part of Brisbane city? What are the important physical qualities of the buildings and landscape of this precinct? How could this area change or be transformed?

Figure 11. Workshop session at the Commissariat Store. (source: Stalker et al., 2013).

Group 4 – Approach, development & outcomes

The author, an academic, was designated to Group 4 as co-leader with Cameron Davies, an architect and director of a leading urban design and architectural practice. Cameron had been a full delegate at the ISUF 2013 conference the previous month, and was therefore conversant with the themes discussed amongst morphologists at the conference, including the quest for better integration of research and practice; it was therefore an ideal opportunity to test this relationship.

The roles for the working group were discussed and agreed; it was decided that the author would develop mapping diagrams of the morphological evolution of the rivers edge and development of wharf buildings, from the period of urban settlement, up to the present. The drawings would be presented and described as a basis of knowledge to inform the understanding of the contextual condition. It would be for the design team to 'interpret' this information and

distill the significant issues along with the other aspirations and demands of the project; to manifest into the concluding design scheme.

Figure 12b is a composite diagram of the changing river edge over time, with each altered profile being mapped from the archival survey information; therefore articulating the morphological development of the rivers edge. This was the key mapping diagram to inform the design process, it was therefore presented to the group as reference material for the design team to interpret.

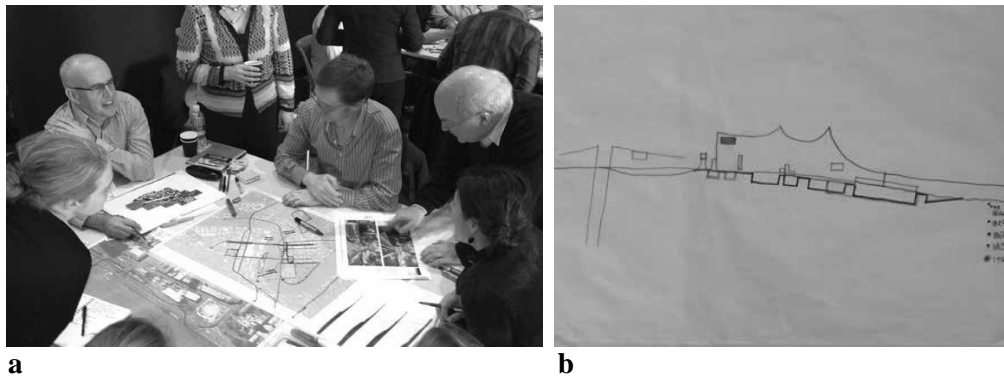

Figure 12a. Group 4 working session. 12b. Composite diagram of changing river edge. (source: Stalker et al., 2013).

The four key principles and recommendation that Group 4 derived from the process were:

- a) Respect, express, celebrate and make accessible to all the rich heritage morphology of the site in its redevelopment;
- b) Create more bridges over the river to connect the city centre to Southbank;
- c) Design the buildings and places to accommodate different uses over long time spans;
- d) Work towards a longer-term redirection of traffic between Alice and Queen Streets so that an 'opening' in the express-way can be created, enabling buildings to link to the river. (Stalker et al., 2013)

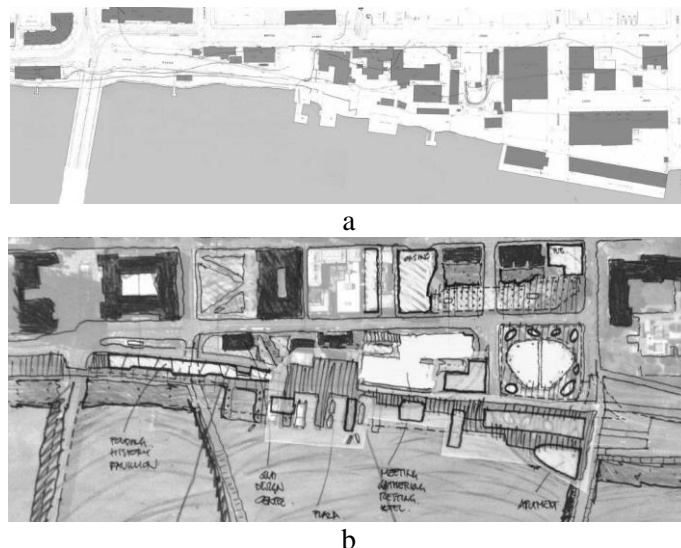

Figure 13a. Adaption of 1913 Water and Sewerage plans. (source: Author/ Brisbane City Archives). 13b. Group 4 final design proposal 2013. (source: Stalker et al., 2013)

Referring to the final Group 4 design proposal (Figure 13b), it is clear that the principles a & d had a profound impact on the direction and outcome of the design project. Furthermore specific aspects 1 and 5 listed below, patently address the lost attributes within the urban form; for example, a corner building of similar scale to the demolished Bellevue Hotel (see Figure 9), and the introduction of a new ‘fragmented deck’ which takes its cue from the original quay and wharf profile, including the design of new dispersed building forms (yellow) which resemble the warehouse structures from the 1913 diagram (Figure 13a).

The specific details of the design proposals included:

1. A new hotel/ pub at the southern end of George Street- (former Bellevue Hotel site)
 2. 80 George redeveloped as two linked towers; if a casino, include it in a tower that opens up Mary St at the ground plane;
 3. Create a great streetscape along William Street;
 4. Adaptively re-use the Neville Bonner building;
 5. Construct a River Quay between Victoria Bridge and QUT which includes a ‘fragmented deck’ whose form interprets the history of the site;
 6. A new design museum in the Old State Library.
- (Stalker et al., 2013).

Outcomes and reflection of the Bridge to Bridge: Ridge to Ridge urban design workshop

Whereas Group 4 undertook a concerted approach to embedding urban morphology into the design process; the outputs from other groups were varied. The following list captures some of the themes in their reports that construe an urban morphological intent within their recommendations.

- Group 1: Respect and enhance the Commissariat Quarter, Brisbane’s most significant heritage precinct located between William Street and Queen’s Wharf Road.
- Group 2: Recognize and celebrate the historic significance of the precinct. Establish a fine grain that creates a destination with character and scale. Recognize and celebrate the historic significance of the precinct; adapt and reuse heritage buildings, provide interpretive facilities, and respect the symbolic importance of the linear spine of George Street. Permit only appropriate scaled buildings adjacent to heritage areas.
- Group 3: Celebrate the historical significance and architectural qualities of the Heritage Precinct. Construct a new Queens Wharf Ferry Terminal (replacing existing) to be sited at its original location on the riverbank in front of the Commissariat Store.
- Group 6: Retain the scale of the heritage precinct – linking it to the river and creating a green space ‘buffer’.
- Group 7: Respect and enhance the heritage quality. Use a development framework (requirements for podiums, a restricted material palette and carefully managed building heights, etc) to achieve these aims.
- Group 8: Manage building heights to enable density while respecting heritage.
- Group 9: Acknowledge area as Brisbane’s first landing site. Restrict building heights around heritage buildings with highest buildings north of George Street.
- (Stalker et al., 2013)

It is encouraging to note that all but one of the nine groups make specific reference for the need to relate new structures closely to the existing heritage buildings: through various approaches, such as: ‘character’, ‘significance’, ‘appropriate scale’, ‘respecting’, ‘acknowledge’ and ‘architectural quality’. These groups thereafter made intuitive design responses to address the strategic intentions indicated above; and not surprisingly the design results from these groups are less explicit than the Group 4 submission. It could be surmised then, that with greater access to morphological data, all groups may have been more specific in design detail towards achieving the intent of the recommendations.

The overall collated outcomes of the workshop have been captured in a wide range of 23 key recommendations; with the three resolutions that best capture morphological aspects as follows:

Development Scale and Form

Preserve the integrity and historic setting of the lower scale heritage buildings by keeping adjacent buildings lower scale and providing buffers to new taller development. Undertake an impact study to determine appropriate scale of new development immediately adjacent to lower scale heritage buildings and nature of required buffers.

The Heritage Precinct

Actively enhance the heritage precinct to improve its enjoyment and accessibility for the people of Queensland. It is the most significant collection of heritage buildings in the state and this should be able to be understood and enjoyed through the design of its setting and its interpretation.

More clearly articulate and demonstrate the experience of the historic relationship between the Commissariat Store and the river in the design of spaces around the building.

The River's Edge

Create a lively, safe and welcoming river's edge. Activate the river's edge with new decks, restaurants, event spaces, cafes and recreation areas in the short term to make it a safe and enjoyable place in the city. Consider noisy activities that can coexist with freeway noise.

Plan for the potential redundancy or staged rerouting of the expressway (including the closure of on/off ramps) so that this highly significant reach of the river can be reconnected to the city in the longer term. (Stalker et al., 2013)

Conclusion

'The attraction to urban morphology from a wide disciplinary base is the nexus of concepts, ideas and approaches' (Samuels, 1990).

The concerted integration of the ISUF Conference event with the local design profession had a positive impact on the urban design workshop, in that the organisers and participants had been made aware of the work of morphologists, and in particular the richness of research data that can provide the knowledge base for designers.

It was also evident that following the willingness of the designers to accommodate research generated knowledge into the briefing and idea formulation stage of a design project, as in the case of Group 4, a clear correlation with the end proposal and important morphological attributes can be achieved.

Therefore it is suggested that research-led design, based on the designers interpretation of the research data, is an effective and accessible method to align theory and practice, and potentially more readily accepted than prescriptive guidelines and controls.

It is hoped that the example presented in this paper will contribute towards the current work that is being undertaken by the ISUF Research and Practice taskforce towards understanding better the *modus-operandi* of practice, and how practical guidelines can be developed to aid the adoption of principles of urban morphology in the process of design.

Urban form study for better future of the city

Anna Agata Kantarek

Faculty of Architecture, Cracow University of Technology,
31-450 Kraków, ul. Ułanów 28, Poland. E-mail: akanta@poczta.onet.pl

Abstract. *A look at the problems of urban forms from the point of view of the practice of architecture, urban planning and urban design is especially needed today. Contemporary sprawling cities and metropolitan areas require a holistic perspective from the point of view of synthesizing Urban Form while maintaining respect for historical tradition and cultural meanings of the place. The research problem boils down to the question of how, through research on urban form in its historical and spatial complexity we can find or formulate models for good solutions for the coherent and harmonious development of the city. The basis for such a specific approach is : understanding Urban Form Study as crucial for better urban design and spatial planning; recognizing a level of Urban Form as a base level of synthesis; understanding locality as a main determinant of the overall Form of the City; finding basic relations between contemporary Urban Form and possibility of its perception.*

Key words: Krakow, Urban Form design; urban structure; contemporary Urban Form.

Understanding urban form

Contemporary understanding of urban form in the Polish tradition of urban planning has its roots in the ideas of Tadeusz Tołwiński²⁶³. The important contribution made by him was the distinguishing of six *city development factors*.

City development factors are: *natural conditions* (physiography and nature); *economic and social affairs*; *fortifications*; *laws and customs*; *means of communication*; *town-planning composition*.

It is crucial to view the role of town-planning (urban) composition as a factor synthesizing all the others. To quote Tołwiński:

„The town-planning composition factor operates in a similar manner in various cultural epochs – it subordinates the often divergent influence of other factors to a certain general construct from which it derives the appropriate form. It crystallizes either as a result of an individual's creative work or as a product of the collective effort of a number of people or even whole generations. (...) As time passes, some cultural movements develop common types of general urban plans. They result from searching and experiments made over long periods of time (...)”²⁶⁴.

Urban composition is also important for K. Wejchert²⁶⁵. In his book "Elementy kompozycji urbanistycznej" (Elements of Urban Composition), he distinguishes some elements of the city structure which he considers significant. He assigns a particular role to the *elements crystallizing a city plan*. They can vary in nature but they always refer to the basic structural principle of the city fabric.

At another level, he identified *streets, districts, edges, nodes, dominants, outstanding landscape elements and characteristic features*. The classification essentially corresponds to

²⁶³ T. Tołwiński was an active architect an urban planner as well as a professor of architecture (Warsaw, Krakow). He wrote a book summing up the achievements of European urbanism – (Tołwiński, 1948).

²⁶⁴ (Tołwiński, 1948, I) p. 28

²⁶⁵ K. Wejchert – urban planner, professor, Faculty of Architecture, Warsaw University of Technology. Author of post-war reconstruction of small towns and a new city called Nowe Tychy, which is an excellent example of urban superblock development.

K.Lynch's division although in Wejchert's terms it refers to the actual structure rather than the elements of perception of the city's image²⁶⁶.

K. Wejchert also defined a *spatial interior*. "All sorts of restraints create a kind of interior around the observer stopping at a specific point regardless of the absolute dimensions of the perceived section of the surroundings."²⁶⁷

An important Polish approach to the understanding of urban form is its interpretation by prof. Janusz Bogdanowski, a pioneer of Polish landscape architecture, in his work²⁶⁸.

Janusz Bogdanowski²⁶⁹ developed the theory of urban interior (Bogdanowski, Łuczyńska-Bruzda and Novák, 1973): „We get to know landscape through recognizing its particular interiors. The interior in this case are the whole physiognomic surroundings of the place from which landscape is viewed. Of course, there can be an infinite number of such places. However, while studying the area, we can restrict their number to a series of those which most fully characterize individual types and forms of the landscape thus usually constituting its nodal points”²⁷⁰.

In brief, urban interior is a spatial unit which makes possible perception of landscape²⁷¹ - perception through fragments (perception based on the senses through presence).

We are dealing here with two points of view.

On the one hand it is the understanding of space through interiors – it is subjective and changeable depending on the time, person, function and use, form. It is the point of view which, through the synthesizing of impressions and opinions, can lead to studies and generalizations forming a set of issues related to the perception of the environment and research of environmental psychologists.

On the other hand, there is a definite physical structure which can be examined also through the study of specific places defined as urban interiors. The division into urban interiors is neither complete nor complementary. However, we can talk about interrelations between these interiors. Both the recording of the structure of the existing landscape and the design methods are based on a more or less conscious division of the landscape into interiors through the cubature forms that shape them. The perception of space through interiors imposes order and allows sequencing. This is related to the recognizing of the existing forms and the reading of cultural meanings.

This is also what both K. Wejchert and J. Bogdanowski mean by urban interior. This way of thinking complements in a sense the approach presented by K. Lynch, G. Cullen or Y. Ashihara who emphasize the manner of man's reception of space.

It lets us confirm the significance of the two different views – through the examining of the form and structure and through the studying of the principles and possibilities of perception of urban space.

At this point, it is worth mentioning the opinion of Roman Ingarden who writes about a two-layer structure of an architectural object – a spatial form and multiplicity of appearances²⁷².

We also ought to present the concept of a *powerful form* introduced by Jacek Gyurkovich²⁷³. A powerful form differs from its surroundings and has great power of expression „(...) it focuses the observer's whole attention distracting it from other elements which participate in the

²⁶⁶ K. Wejchert carried out studies on the curve of impressions thus joining in the debate over perception of urban space.

²⁶⁷ (Wejchert, 1974) p. 25

²⁶⁸ <http://www.la-congress.pk.edu.pl/rejestra.htm>

²⁶⁹ J. Bogdanowski was professor at the Faculty of Architecture, Cracow University of Technology, a historian, urban planner, landscape architecture and a theorist. He authored a number of studies on the history of Krakow's urban development – its greenery, fortification systems and landscape.

²⁷⁰ (Bogdanowski, Łuczyńska-Bruzda, Novák, 1973) p. 19

²⁷¹ Landscape is the physiognomy of the environment (the earth's surface) which is a synthesis of natural and cultural elements. Ibid, p. 76.

²⁷² Cf. (Ingarden, 1958), (Ingarden, 1981), (Gołaszewska, 1984)

²⁷³ (Gyurkovich, 1999).

creation of spaces and reducing their role to that of a background”²⁷⁴. At the same time, it assumes their meanings and constitutes a basis for the crystallizing of characteristic spatial sequences²⁷⁵. It is attractive and has the power to compose the surroundings. The term form is used here in relation to the space as a whole rather than cubature forms alone. The term can also apply to important public spaces which act as nodes²⁷⁶.

Such an approach to the urban form is presented in the paper (Kantarek, 2013 b) and defined as a *four-dimensional Capacity*:

"A vision of the form of a city as a physical, three-dimensional extension is the basis for understanding numerous theories. It is supported by a realistic attitude which assumes the existence of real, recognizable entities independent of consciousness²⁷⁷. In the most general sense, we can imagine a uniform, three-dimensional universe with a permanent location of points in relation to selected directions. These directions, defined naturally, mean the horizontal (X-Y plane) and the vertical (Z). In such a rationalized space, its initial (only imagined) uniformity practically includes various kinds of realness. It can be a man – a person whose realness is more than physical; there are other forms of matter, too, including visible elements – topography, greenery and architecture. The air is treated involuntarily as a “lack” although it makes a space of the same type as visible matter. The diversity and richness of spatial forms as well as time and the transformations of matter in time overlap on such a basic model. Such an imaginary four-space “stage” is the environment of life in its broadest sense, first and foremost the life of an individual and a community. This approach makes it possible to see the city in a geometrized scheme of inventory and morphological character. Four-dimensional capacity can also establish and assume an unlimited number of other, immaterial dimensions which differ from each other (e.g. in the sphere of meanings, emotions, applications, descriptions, histories etc.). In such a universe, it is also possible to continue defining certain wholes, always with the guarantee of geometrical precision as far as location, distance and size are concerned.

Four-dimensional capacity as an initial vision of the city of complete and holistic character is the basis for many well-known theories. This basis is realistic, not phenomenological.”²⁷⁸

A few words about the contemporary spatial planning in Poland, Krakow case

The present-day system of spatial planning in Poland is far from perfect. It results from the overlapping of some elements of the central planning system which was a rule before 1989 and the policy of openness to private investments in the transforming state economy that ensued. The planning system based on master plans which guaranteed systemic and comprehensive solutions, supplemented with detailed plans, was replaced with the *Study of the Conditions and Directions of the Spatial Management of a Commune - Studium uwarunkowań i kierunków zagospodarowania przestrzennego gminy* which is general and does not act as law. Local legal regulations are executed basing either on *Local Spatial Management Plan - Miejscowy Plan Zagospodarowania Przestrzennego* (which is not obligatory) or administrative decisions. These decisions refer to private investments (*Conditions of Development and Spatial Management – WZiZT Warunki zabudowy i zagospodarowania terenu*) or public investments (*Decision on the Location of Public-Purpose Investments - ULICP Decyzja o ustaleniu lokalizacji inwestycji celu publicznego*) and are separate spatial management decisions with no coordination between one another or other decisions (often the systemic ones concerning communication loads, for example) What is more, their compliance with the *Study*²⁷⁹ is controversial and disputable.

²⁷⁴ Ibid. p. 7.

²⁷⁵ Ibid. p. 169.

²⁷⁶ An interesting comparison can be made in relations to Aldo Rossi's artefacts.

²⁷⁷ (Leksykon, 2000), p. 282

²⁷⁸ (Kantarek, 2013 b), p. 31n

²⁷⁹ *Study* will be used as a shortcut for the *Study of the Conditions and Directions of the Spatial Management of a Commune - Studium uwarunkowań i kierunków zagospodarowania przestrzennego gminy*.

To sum up, it can be said that urban space defragmentation starts already at the stage of the legal system of planning.

It is worth considering certain aspects of the integrity of the spatial structure of Krakow in the light of the legal conditions of recent years. The last binding master plans which referred to the whole city area were made in 1988 and 1994. The 2003 plan was a *Study of the Conditions and Directions of the Spatial Management of a Commune* and as such had no force of local law. The 1988²⁸⁰ Master Spatial Development Plan of the City of Krakow (Miejscowy Plan Ogólny Zagospodarowania Przestrzennego Miasta Krakowa) defined a general spatial policy which the City Council wished to adopt with a view to returning to the traditional urbanism of streets, squares and urban blocks as well as respecting the values of particular districts as reflected in the formula of "a city of small towns".

The plan specified 50 spatial planning zones which were divided by themes into the following groups: landscape and natural resources protection zones; cultural resources protection zones; environmental protection zones; sanitary and protection zones; technical zones; transit services zones; municipal policy zones; investment policy zones; health resort protection zones.

They linked functional requirements with the specification of prohibition, obligation and protection measures.

The 1994²⁸¹ Master Spatial Development Plan of the City of Krakow (Miejscowy Plan Ogólny Zagospodarowania Przestrzennego Miasta Krakowa) uses two clear categories which determine the development. These are *land use* and *conditions of development*.

Land use is defined in terms of 19 different functions /purpose/ while conditions of development are determined by the establishing of spatial management policy zones. They include: the environment and nature protection zone, landscape and cultural heritage protection zone, view protection and view shaping zone, building intensity zone.

The first two zones are the most important ones with prohibitions and restrictions having priority over permissions.

The four zones are further subdivided to reach a total of twenty.

The plan shows a division of the area of Krakow into particular fragments each of which has been ascribed a code that is a combination of the function and obligation to meet the requirements of the 4 basic zones. 344 possible combinations have been distinguished.

The graphic form of the plan shows graphic symbols representing continuity of particular themes (Figures 1, 2).

Although the layout of the plan is legible, logical and safeguards the value of the urban form, designers regarded it as too complicated and employing hermetic terminology. In the late 1990s it was common to think about a city structure in terms of a whole as insignificant. What mattered most in the investment policy of the city authorities at the time (like today, unfortunately) was to give proprietors functional and spatial freedom in developing particular areas, which was seen as the only way to boost economy and growth. As the spatial planning system in Poland changed leaving it to the communes to take up or not to take up planning activities and restricting local plans to small investment areas without precise regulations ensuring compliance of *Local Spatial Management Plans* with the *Study*, the 1994 plan for Krakow was also overridden by the 2003 *Study*.

The 2003 *Study* regulations continue to protect the values contained within previous plans although they are rather general and descriptive.

The plan distinguishes 12 functional possibilities giving investors more freedom to develop the areas.

As for the description of spatial structures, the plan makes clear distinctions between function, form and zoning of the centre and the outskirts.

²⁸⁰ (Plan I, 1988), general designer of the plan is prof. Zygmunt Ziobrowski.

²⁸¹ (Plan II, 1994); as in the case of Plan from 1988 prof. Zygmunt Ziobrowski is the general designer and the coordinator of the plan.

According to the 2003 Study, the spatial structure of Krakow includes: the historical city centre with the surrounding built area; the area of "old" Nowa Huta; complexes of multi family housing; complexes of single family housing; high density industrial areas; transportation system; greenery and open spaces.

The main elements forming the spatial urban structure include: urban centre; main streets; main urban routes; multi functional urban centres; key areas of economic, cultural and technological development; greenery.

An attempt at saving the integrity of the urban space of Krakow was the study which won the competition for Local Revitalization Program for Krakow²⁸². The aim of the study was to present a general idea of revitalization of the city which is necessary because of both social and spatial problems.

Seven levels of revitalization were indicated from retrofitting and scale of a particular building or plot, various urban complexes, through systemic actions in selected areas and integration of the community and space of the whole city. The work resulted in a proposal to draft some necessary documents such as a map of acceptable sizes and a map of significance.

Figure 1. The 1994 plan – fragment of the graphics, (Plan II, 1994).

The authors chose several major areas where revitalization should be carried out. In view of the obvious shortcomings of the urban planning law, the basic level was the scale of the whole city and the need to include in the revitalization program the guidelines referring to the integration of city space and modernization of spatial systems of different nature.

An analysis of urban space was the basis for the assumption that revitalization should cover both "*the central areas of the city and the adjacent sites which showed a lack or insufficiency of use intensity /the ring around the centre of Krakow/, as well as local centres /residential and industrial/ together with systems based on the values of natural and cultural environment.*"²⁸³. Unfortunately, the study was not used at a general level. It allowed identification of the most vulnerable areas designed for revitalization while further administrative procedures resulted in the creation of a bank of particular projects and local interventions basing on the binding urban planning law.

Both the 1994 Plan and the study which won the competition for Local Revitalization Program for Krakow are attempts at a comprehensive approach to the urban form of the city and the establishing of effective rules of urban development that would allow conservation and creative interpretation of the city's cultural heritage.

To what extent is it possible to define such rules given contemporary Polish law? A possible solution could be the strengthening of the role of the *Study of the Conditions and Directions of*

²⁸² (Kantarek A. A., Gołab-Korzeniowska M., Karczmarska E., Motak M., Noworól M. and Tchórzewska A., 2006)

²⁸³ Ibid p. 8

the Spatial Management of a Commune and the extending of the projects which would allow a comprehensive approach to the themes it includes but not in the form of further changes in the document but as a basis for supplementary projects that would specify the general guidelines wherein.

The steps that should be taken in the first place include: the drawing up of a map of acceptable size with the monitoring of views and vistas from important locations, the forecasting of the effects of the decisions concerning function (which is missing in the planning of the city's transit system), the preservation of historical content and meanings of public spaces²⁸⁴ and finding a formula for active construction of a network of the city's public spaces²⁸⁵. Obviously, even the best *Local Spatial Management Plan* cannot enforce decisions that concern the sequencing of public spaces, obligation to buy out spaces and maintain their high standard.²⁸⁶

Visions and ideas

They are extended proposals submitted to the ISUF Manifesto.

1 Urban form research for better urban design and spatial planning	An important research field of urban form is associated with finding models of good solutions for today's tasks in the field of urban design and spatial planning
2 Urban form as a crucial level of synthesis	From the point of view of an architect and urban planner , practitioner and theorist , it is important to look at the form of the city as synthesizing other /and all/ guidelines - from politics to culture, from the community scale to the scale of the individual.
3 Locality and the overall form of the city	Locality is increasingly seen as the only significant scope for the life of the people. Overall reflection says that the body develops in the environment at the same time contributing to this environment . It is therefore a basic range of synthesis . Such an understanding of locality and urban form requires us today to look at the overall form of the city or agglomeration and finding such research tools that are able to describe it in all its complexity and dynamics of development.
4 Urban form and its perception	My point of view is that in urban form research seeking good models for today it is extremely important to carry on the double look – through the description of the structure/form and through the principles of its perception. At the junction of these studies we have an extremely important range of studies related to orientation in space, orientation understood as the basis for use of the space.

Figure 3. Main proposals submitted to the ISUF Manifesto.

²⁸⁴ Lack of regulations concerning protection of unique public spaces leads to their appropriation. An example to the point in Krakow is the current fight for preserving public space integrity and the modernist form of the Cracovia hotel. The new owner of the hotel wants to build over a part of the traditionally shaped public space in front of the hotel which is an element of a sequence of views from Old Town towards green areas on the west of the centre and destroy the valuable modernist architecture..

²⁸⁵ Within the same legal framework, Polish cities deal with spatial planning in different ways. Wrocław is particularly successful in implementing the comprehensive approach of *Study* both as regards decisions about functions and the creation of articulate public spaces.

²⁸⁶ A relevant example in this respect is ul. Cystersów (Cistercian Street) in Krakow which is included in the plan and yet cannot provide the proper standard of its public space for adjacent housing, for which it is designed. (Kantarek, 2013 a)

Wider comment on the proper meaning of the idea of locality is necessary. The text above highlights the significance of this spatial level. The important relationship between an individual and the environment is vital since life is realized at this very level. Individuals and the environment feed on one another.

For man, a four-dimensional environment (physical space + time) is important from the point of view of his growth and self-realization not only at the physiological level but also the psychical, emotional, intellectual and spiritual ones. It is at this level that he develops his axiology and approach to universal values. It is the local-universal relations that matters more than reference to the global scope. In such terms globality is assimilated by locality and not vice versa.

Globalization, which allows multiplication of the processes of tightening relations (including the economic, technological and financial ones) worldwide between countries and nations, fosters exchange of information and gives access to a wider scope of knowledge, can be viewed as a source of many opportunities including a need for compromise and standardization. However, it poses a threat to cultures which are based on locality.

Obviously, today, to a much lesser extent, the environment in which we live are related spatially. Even the spatial environments are often broken up into isolated parts which are separated by the time and sections of travel. However, none of these arguments means that the four-dimensional space and its legible functioning and composition are now less important.

Perhaps the solution would be to develop the *Open Book on Urban Form of The City* (whose scope is inexhaustible so it should be continued and updated) which would have the following aims: to show the complexity of the urban structure as a whole in relations to its history and meanings, also in a broader context (region, nation, country); to show significant established models of development of the elements making up the whole (areas, systems); to show the possibilities of the areas that are not formally shaped or underdeveloped in the shaping of the urban form

An important aspect of such a book is the social and environmental context.

This book should relate to a specific city. *Open Book on Krakow Urban Form* should include the following problems: The starting point ought to be a synthesis of the knowledge about the whole urban structure and the elements of its form in terms of history and meaning. There is a wealth of information on Krakow to be found in numerous studies and encyclopedias as well as the binding *Study*; Significant models in the case of Krakow certainly include: urban block forms that result from the implementation of defined systems and shaped in various historical epochs through the parceling out of streets, modernist housing estates as well as the public spaces of the historical districts of Krakow Old Town and Kazimierz.

This is the least explored scope of the urban form content. Regular studies should start with the determining of the current division of the city into development urban superblocks according to transportation routes and their declared and actual loads (which determine the role of a road in land development – transit or link).

Other areas of research include: categorizing views /sequences of views, sites, kind of stay/; categorizing typo morphological content; defining possibilities of transformations /fabric development/ in relations to the existing and historically legitimate elements/.

Development of a complete study of this kind seems unfeasible in terms of time. However, some things need to be done since they are particularly important for Krakow. These are: conservation, protection and development of complete urban spatial systems; in particular, protection of the network of open and accessible public spaces which emerged within the established historical and functional system of public spaces including protection of public spaces for pedestrians with the accompanying activities; conservation of modernist heritage – both objects and public spaces; preventing urban thinking by isolated functions (gated areas) which get detached from the common public space; protection of the basic street system (including "town entrances") with its legible layout, without acoustic screens and a barrier of advertisements as well as the chaotic visual and functional enclosures. Creation of proper

synthesis of pedestrian traffic and the accompanying activities of street ground levels as well as car traffic, public transport and parking zones is a must.

Such a book should not only be an analytical material for spatial planning and design but should also define good, from the point of view of urban form, ideas of its development and transformation and necessary legal obligation.

The morphological dimension of planning documents: case study Belgrade, capital of Serbia

Ana Niković *, Vladan Đokić **, Božidar Manić *

* Institute of Architecture and Urban & Spatial Planning of Serbia, Bulevar kralja Aleksandra 73/II, 11000 Beograd / Serbia. ** Faculty of Architecture, University of Belgrade, Bulevar kralja Aleksandra 73/II, 11000 Beograd, Serbia. E-mail: anan@iaus.ac.rs, vdjokic@arh.bg.ac.rs, bozam@iaus.ac.rs.

Abstract. *The aim of this paper is to present one of the main issues and tasks of the ISUF – the importance of introducing concepts of urban morphology to professional practice, in a systematic and coherent way, to achieve a better built environment - in the specific context of Belgrade. A review of relevant up-to-date research topics and developed concepts found in the current theoretical discourse presented in the Urban Morphology Journal and ISUF, such as: morphological dimension of municipal plans (Oliveira), the issue of boundaries (Whitehand, Larkham and Morton), the question of scale and key concept – block or tissue (Kropf, Samuels, Hall) will be conducted. A number of major themes in the agenda of the morphological debate, will be examined to establish how existing morphological criteria in the Master plan of Belgrade and related planning documents correspond. It was determined that the morphological dimension of those criteria is questionable and that the real form-based approach in Belgrade's planning documents and procedures were absent which had a detrimental impact on the quality of physical and urban structure. It can be stated that there is a need, firstly, for a detailed theoretical elaboration of relevant concepts of urban morphology and then integrating them into planning documents and procedures in Belgrade and Serbia. The principal conclusion reached is that urban morphologists should have a key role in the prescription of future changes through coordination of design guidance, codes and plans at different scales.*

Key Words: Belgrade, urban morphology, urban form, planning, designing

Introduction

This paper builds on the existing researches dealing with the morphological dimension of urban plans in specific contexts of urban planning, the results of which are a part of contemporary urban morphological discourse exposed within the ISUF research database. The title of the paper directly refers to Oliveira's investigation of morphological dimension of urban plans for the city of Porto (Oliveira, 2006), pointing to the similar method and theoretical background to be used in case study of Belgrade, the capital of Serbia. Linking up and building on the results of past researches in the field of urban morphology provides multiple contributions. On one hand, urbomorphological investigations offer a significant theoretical base and direction for improving planning practices in Belgrade. On the other hand, international framework of urban morphology is expanded and a number of issues are examined in the specific context of discontinued development of Belgrade that is thus put in relation to continuous development of western countries whose experiences are primarily represented within ISUF (Whitehand, 2012.).

In Belgrade, over the past decade significant morphological changes have occurred due to huge pressures for increasing of building capacities, either through planning new or reconstructing the existing physical structure. The pressures mostly come from private investors driven by their economic interests, which become dominant in the decision-making processes. The resulting quality of the built environment is highly unsatisfactory, leading to erosion of character of the existing urban entities. The problem is particularly evident in the central zone of Belgrade which includes the historical city core, the center of New Belgrade and Zemun. In all these parts of the city that have different and specific historical developments, uncritical

interventions have been emerging not taking into consideration the existing urban forms and building typologies.

The existing planning documentation for Belgrade – primarily the current Master Plan of Belgrade 2021 (Urbanistički zavod Beograda, 2003) which acts as the planning basis of a higher level compared to detailed urban plans – recognizes the significance of preservation of the character as well as the opening of possibilities of new development within the existing urban entities. However, the planning guidelines do not offer the way towards achieving these goals, neither can they follow and control the undergoing urban transformations. The problem lies in an insufficient or inadequate direction for the detailed building level, through the planning recommendations that neglect the aspects of the resulting urban form. The question that arises is: in what way would it be possible to enhance the planning documentation and consequently the practice, by using the concepts of urban morphological discourse and recent experiences in linking these theoretical concepts with the practice? The unanswered question is: what happens in case of successful improvement of planning documentation in this way, how to ensure its successful implementation, where the key role of urban morphologists in coordination of design guidance and codes in plans at different scales can be recognized.

Context of the research

Oliveira (2006) puts his research in the context of the attempts to integrate the urban-morphological methods and concepts into the practice of urban design and planning, performed by the members of the contemporary British morphological school – Karl Kropf, Tony Hall and Yvor Samuels – as co-ordinators of urban plans and studies for several settlements in France and England. Then, he conducts a comparative analysis of these documents to the methodology applied in developing the plan of the city of Porto co-ordinated by Fernando Ça who builds on the morphological theory of Gianfranco Caniggia.

Introduction of the specific morphological criteria creates a methodological framework for protection of the existing historical and regional values, as well as for the formation of the new fabric. Based on the comparative analyses of the selected plans, Oliveira notices research topics and issues that are relevant for discussion and establishment of relation between the urban morphology and urban design. He especially highlights the issues of city character, typomorphological approach to zoning, the concern for urban tissue and levels of resolution as well as the question of boundaries.

Oliveira implies the possibility of improving the content of plans by including illustrations of acceptable typologies of plots, buildings and architectural details based on the morphological analyses of surrounding sites. Although these elements are not legally binding, if taken into consideration during implementation, they can contribute to the quality of the built environment because they take into account the relation between the existing and the new urban forms, thus preserving the character and the continual development of the specific areas.

Issue of boundary and scale – character and homogeneity.

The issue of boundary represents one of the key indicators of morphological dimension of plans because it addresses an important planning standpoint – which area is delineated, how and why (Larkham and Morton, 2011, Birkhamshaw, 2006). In accordance with linking urban morphology and planning practice, the boundary that encompasses the subject area should be based on morphological analyses of urban and physical structure. It should display the scope of the area with the homogenous morphological characteristics for which the spatial policies, planning guidelines and design rules have been defined.

Key concept – block or tissue

One of the basic interests of urban morphology in making its knowledge applicable in practice is the definition of the key concept. In that term, Kropf talks about urban tissue as the basic growth and transformation unit (Kropf, 2006, 2011.), while Hall and Samuels suggest block structure (Hall, 2008, McGlynn and Samuels, 2000). The concepts of tissue and block are related in terms that the tissue can be defined as the series of blocks of homogenous structure interrelated with street network. By morphological analysis of a particular area, a continuous expansion of a specific type of block can be identified together with its variations which generate the area of homogenous characteristics. This generative boundary is of special importance in contemporary morphological studies because, unlike the administrative boundaries of municipalities or designed boundary made up for the purposes of design brief, it recognizes morphological – intrinsic qualities of urban structure. In the Conzen's terminology, the generative boundary stands for „fixation line“ (ISUF Glossary). The use of this approach in defining the boundary helps avoid the frequent problem of administrative boundaries intersecting with parts of urban areas with similar morphogenetic characteristics (Whitehand, 2007).

Planning regulations

The design rules can be given explicitly, in the form of quantitative indicators which are obligatory for obtaining building and use permits, or implicit, in the form of qualitative descriptions that offer possibilities for different solutions in designing (Tieben, 2011). The way in which the design rules are formulated and used most directly influence the quality of the built environment. They link the different scales of professional activities, i.e. macro-scale of planning with the micro-scale of designing.

In accordance with the theoretical discourse of urban morphology, the morphological dimension of planning documentation implies the presence of morphological methods and concepts which address planning guidelines to resulting qualities of urban and physical structure. The paper is particularly concerned with the abovementioned topics in the agenda of the morphological debate in order to establish how existing morphological criteria in the Master Plan of Belgrade 2021 and related documents correspond.

The case of Belgrade

The system of planning in Serbia is similar to those in most countries that use the approach of comprehensive planning and principle of hierarchical linking from larger scale of spatial/regional plans towards smaller scale of urban plans. According to the scope of the subject area, urban plans have their own hierarchy to be obeyed: from master plans, via general regulation plans, to detailed regulation plans. The regulatory framework for the planning system is the Law on Planning and Construction (Zakon o planiranju i izgradnji, 2009), Rulebook on the Content, Method and Procedure for development of Planning Documents (Pravilnik o sadržini, načinu i postupku izrade planskih dokumenata, 2010) and Rulebook on General Rules for Land Plotting, Regulation and Building (Pravilnik o opštim pravilima za parcelaciju, regulaciju i izgradnju, 2011).

According to these documents, the integral parts of both spatial and urban plans are the rules of regulating, building rules and graphic part of the plan. The rules of regulating contain the concept of urban development of characteristic zones and entities, urban and other conditions for regulating, building and developing public areas and infrastructure network, measures for protection of natural, cultural values, energy efficiency, standards of accessibility etc. The building rules contain the type and use of structures that can be erected in specific zones, permitted urban parameters, maximum building height as well as conditions for forming a

buildable plot, positioning of buildings on the plot, building other structures on the same building plot and providing the access to plots and parking lots. The graphic part of the plan shows the planned use, regulation and leveling, infrastructural systems, protection of the environment, natural and cultural goods etc. It is done on notarized underlays – cadaster-topographic, cadastral or topographic maps or on updated ortho-photo underlays.

The building procedure starts with the request for issuing the location permit which contains the information on the possibilities and limitations for building on the given plot. The information is excerpted from the detailed regulation plan for the subject area – if it exists. However, since the city territory is not completely covered by detailed regulation plans, the Law enables the issuing of location permits based on the planning documentation of higher degree, such as the Master Plan of Belgrade 2021. Although it is defined as a comprehensive strategic document, it contains the regulatory elements that enable the issuing of location permits for those parts of the city that do not have detailed regulation plans (Fig. 1)²⁸⁷. Besides, the comparative analysis of the planning guidelines from the Master Plan of Belgrade 2021 and the Detailed Regulation Plans for several entities in the inner city centre show that legally binding elements – maximum permitted values of urban parameters – have not been reconsidered while developing more detailed planning documentation in order to adjust it to the specific context of the subject area. The domination of economic interests of private investors always dictate the attaining of maximum building capacity on the plot (Nikovic et al., 2012). The most common situation is that the maximum permitted values of urban parameters are directly and uncritically transferred from the Master Plan to Detailed Regulation plan. Thus, the rules of regulating and building rules defined in the Master Plan of Belgrade 2021 often directly influence the resulting urban and physical structure. Therefore, it is important to question its morphological dimension, considering the exposed objectives, priorities and planning recommendations. It is also possible to assess its influence on the built environment in view of the period when it was adopted.

Morphological dimension of Master Plan of Belgrade 2021

Master Plan of Belgrade 2021 which is still in effect was adopted in 2003. Its development was explained by the needs of a new social system which “develops gradually and requires a new plan that directs its urban development”. The earlier urban plans were qualified as static because they didn’t provide the answer to the dynamic planning process where the priorities needed to be continuously re-evaluated. It is also emphasized that from the period of the 80-ies of the 20th century the loss of control over urban development occurred. It was manifested through different informal and illegal building activities which were taking place not only in the outskirts but in the central zone as well.

The content analysis of the Master Plan of Belgrade 2021 points out the goals that refer to the improvement of quality of the built environment. The urban development of Belgrade is targeted towards achieving the etiquettes such as “urbanistically regulated city”, “city of complex memories”, “city of unified appearance”, “connected and accessible city”. The relevant chapters which are further analyzed in order to find the elaboration of these objectives are as

²⁸⁷ Total area covered by the Master Plan of Belgrade 2021 is 77602 ha, where 84% of that is urban buildable land – 65185,7ha. Fig. 1 shows the scope of detailed regulation plans where: plans adopted by 2003 include the area of 12986,4 ha, which amounts to 19,9% of urban buildable land. Plans adopted after 2003 include the area of 5502,9 ha which amounts to 8,4 % of urban buildable land. That leads to the fact that about 71,7% of the urban buildable land area is not covered with detailed regulation plans, with the notion that for one part of this area obligation for developing detailed regulation plans is set out by the Master Plan. Additional attention should be paid to the fact that the areas ‘not covered’ by the plans are not continuous, they appear as gaps that need to be „filled-in“ and are present in all parts of the city including the most attractive central locations. That additionally calls upon typological approach to zoning and defining the urban rules according to analyses of the existing urban form.

follows: “Boundaries of the Plan, Spatial Entities and Zones”, “Protection of Space”, “Spatial Zones and Urban Entities with Same Building Rules”, “Urban instruments for implementation of the plan” and “Rules for Building and Renewal”.

Figure 1. The urban buildable land of the Master Plan of Belgrade 2021 with the areas covered by Detailed Regulation Plans.

The remainder of this paper examines how existing morphological criteria in the Master Plan of Belgrade 2021 correspond to the underlined urban morphology issues: the question of boundaries and scale of plan units, key concept – block or tissue and the way of defining the urban regulations. For each of these questions, we firstly describe the relevant elements from the plan, secondly we comment on these elements in terms of existence or absence of its morphological dimension, and finally give the recommendations for its adjustment to urban morphology.

Issue of boundary and scale – character and homogeneity

According to the Master Plan of Belgrade 2021, the encompassed territory of Belgrade is divided into 4 spatial zones: Central, Middle, Outer and Edge, that are further split into 57 urban entities. For each entity or group of similar entities spatial distribution and scope, as well as a short summary of characteristics, potentials and role of the entity in the city are given. The program elements are not methodologically treated in the same way in all entities, but are rather given in the scale of general recommendations for group of entities up to detailed guidelines for specific location. It is emphasized that the main operational purpose of this part of Master Plan is to provide a kind of program reminder for the key developmental issues in specific parts of the city in order to preserve its identity. At the same time, based on the graphic part of the plan entitled “Spatial Zones and Urban Entities with Same Building Rules“ it can be assumed that these urban entities should correspond to the definition of the Conzen’s ‘plan unit’ (ISUF Glossary), i.e. they should be a part of urban areas with homogenous morphological characteristics and distinctive character in comparison to the surroundings. Besides, the division of the plan’s territory into spatial zones and urban entities (Fig.2), can lead to the conclusion that the urban development of Belgrade went on continuously through concentric expansion of

its urban and physical structure from the center towards the outskirts. However, examining of both of these assumptions ends up with its denial.

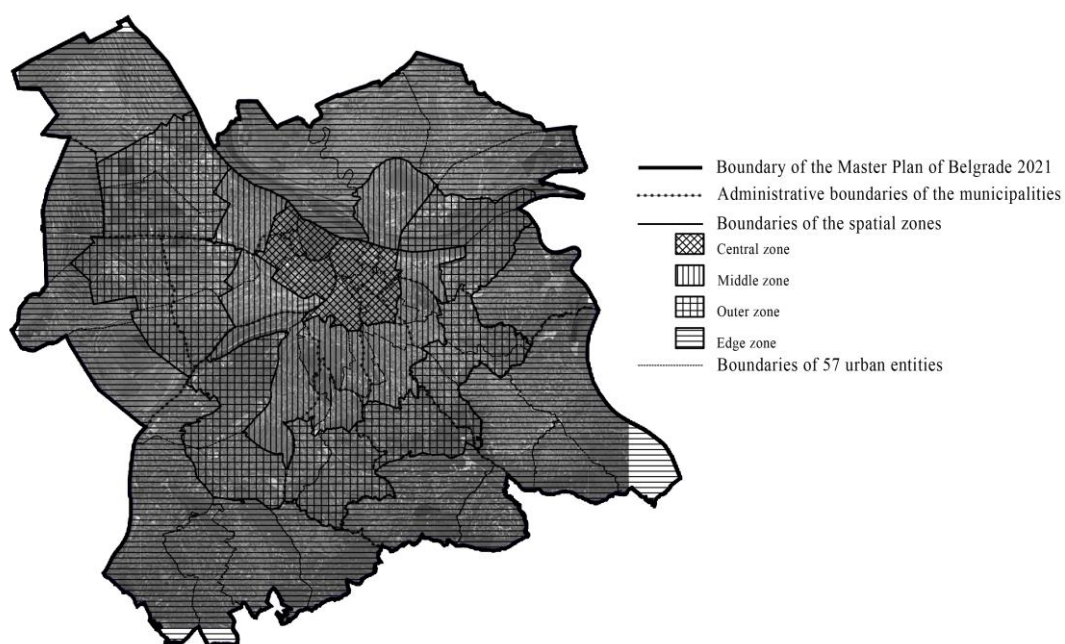

Figure 2. The territory encompassed by the Master Plan of Belgrade 2021 and its division into spatial zones and urban entities.

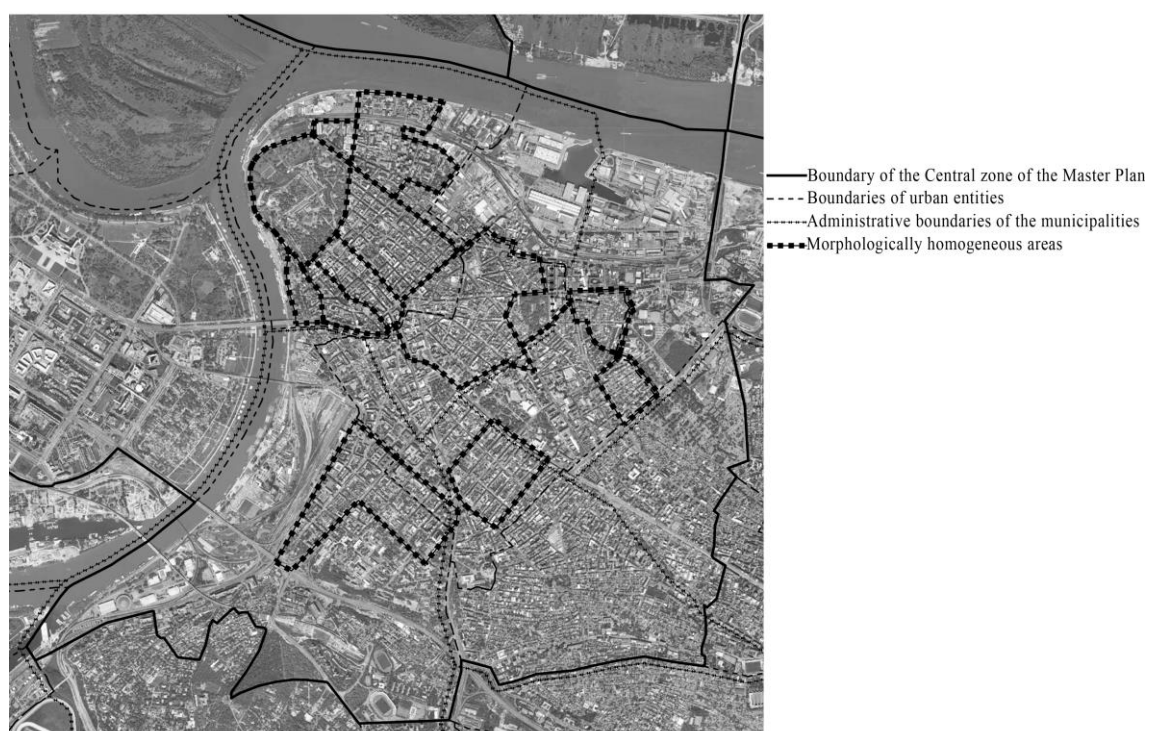

Figure 3. The relation of administrative and plan boundaries to the morphologically homogeneous entities.

Firstly, based on the projection of boundaries in the ortho-photo images as well as via direct observation, it can be noticed that within designated urban entities there are elements of urban and physical structure with heterogeneous morphological characteristics, and that the boundary between the urban entities is frequently cutting through morphologically homogenous areas (Fig.3). One of the explanations of this situation can be found in the plan itself, where it says that the boundaries are partly following the administrative borders of municipalities due to the use of data that are processed at the level of their statistical circles. It is denoted that therefore boundaries can be the subject of future changes.

Secondly, opposed to the assumption of continuous development and concentric expansion of the urban territory, Belgrade's urban development can be described as a set of fragmented interventions, the part of which is evidently aimed towards bypassing the legislation and planning guidelines. Due to illegal construction, the city has for years expanded beyond its limits, for the purpose of building in the cheaper zone, while the central parts remained undeveloped and neglected (Stojanović, 2008.)

The Master Plan of Belgrade 2021 defines urban areas, buildings and conditions that cannot be subject to changes – defined as fixed elements and permanent values of the city. However, this part of the plan has a descriptive character and given recommendations are not obligatory. The protected areas are displayed in the graphic part entitled “Permanent Goods” - not in the main body of the plan but within the documentation basis and are not linked with the abovementioned division to urban entities for which specific building rules are defined.

It can be stated that the division into spatial zones and urban entities, for which the same building rules are applied within the Master Plan of Belgrade 2021, should be reconsidered and upgraded with the urban morphological approach. The boundaries of the urban entities should be generated based on the morphological analysis of the subject area. The scope of the bounded area, i.e. its scale, should be determined by the extent of urban and physical structure with homogenous morphological characteristics, which give the specific character to the urban entity. Also, there is a need for establishing the relationship between the goals of urban design and aspects of physical structure, in which Hall's investigation on the physical manifestation of the planning objectives can be helpful (Hall, 2008).

Key concept – block or tissue

Within the Master Plan of Belgrade 2021 the notions of „tissue“ and the application of morphological criteria can be found in the chapter entitled “Typology of the Residential Tissue” where it is explained that the “types of residential tissue – blocks, included in this MP, are defined on the basis of the morphological criteria”. Accordingly, the planning guidelines for residential use are given on the ground of the following typologies: compact urban blocks, open urban blocks, individual housing blocks, suburban housing blocks and mixed urban blocks. The plan uses the term “residential tissue” for all plots and buildings that are intended for residential use with accompanying public facilities. Since the residential use covers almost 50% of the land intended for building, it can be concluded that proposed typological approach has considerable impact on urban and physical structure of Belgrade.

If the established plan typology of residential tissue is compared to the existing built environment in Belgrade, one can notice numerous flaws and incoherencies between the terms and methods used in the plan with their meaning and application in the urban morphology discourse. The plan shows the tendency to link the planning guidelines with the typology of urban and physical structure, suggesting the type of block as the key concept. However, the proposed typology is too general, based on few characteristics of block structure - the way of grouping and the type of building within a block. Some important block characteristics as elements of typology are avoided. For example, according to recent morphological studies, the shape and the form of block indicate the possibilities of urban development (Siksna, 1997), so it is very important to make a distinction between compact blocks in various parts of the Central Zone of the Master Plan. There are important differences between small square blocks in the

inner city centre and huge elongated rectangular compact blocks on Savska Padina (Perovic, 2008). According to the plan, they both belong to the same type of compact blocks in the central zone intended for residential use. However, their morphogenesis and the existing physical structure differ significantly and require different approach to planning. Also, similar conclusion has been reached when comparing open blocks in New Belgrade to open blocks in the Middle and Outer zone of the Master Plan. This kind of approach to forming the block typology, that doesn't sufficiently take into account the diversities between different parts of the city, leads to the conclusion that the real typological approach to zoning in the plan is absent. The terms such as "morphological criteria" and "tissue" are used in an inconsistent manner. This terminological inconsistency is additionally emphasized by using terms "housing" and "apartment" in accordance to the Habitat Agenda, which has completely different theoretical background.

Morphological criteria in area descriptions and development prescriptions, as well as the used terminology can have proper purpose if they are used in accordance to the urban morphological approach and its methods and concepts. The term of "tissue" should not be linked to the use but to the specific urban entity and its physical characteristics that reflect the homogenous structure of blocks. Also, when defining the typology of blocks it is necessary to conduct a detailed morphological analysis that should result in producing the data on various developmental and physical characteristics of blocks. It is especially important to take into consideration the morphogenesis of blocks, shape and size of blocks, position in wider city entities, topography, etc.

Urban planning regulation

In accordance with the common legislative practice in Serbia, the Master Plan of Belgrade 2021 uses quantitative indicators for determining the building capacity – the Occupancy Index (OI) and the Construction Index (CI) of a lot/block. The permitted values are assigned to specific locations based on the planned use, the position within the city area whether in the central zone or outside the central zone, and in the case of residential use, depending on the type of block. Other guiding indicators for detailed plan elaboration include: population density, employment density, users' density, the ratio between Gross Unfolded Building Floor Area (GUBFA) and commercial use, normatives for open and green areas per inhabitant or per block area.

Apart from determined urban indicators, parameters and regulative elements, in chapters referring to building rules, the Master Plan provides recommendations that are directly linked to the possibilities of energy efficiency, the use of alternative sources of energy, formation of highly standard urban spaces in terms of hygiene and ambiance, establishment of the system of green areas etc. However, these recommendations are not obligatory requirements to be met in designing procedures, as is the case with the permitted values of the OI and CI. Planning guidelines which refer to the elements of urban and physical structure directly connected with qualitative properties of urban space, especially spatially-experiential and visually-aesthetics aspects which are crucial for the city of "complex memories", "unified appearance" etc. are not a decisive factor for the implementation.

The absence of morphological criteria when conceiving the boundaries and typologies of urban and physical structure leads to the application of general rules in the settlements of different character. The application of the Rulebook on General Rules for Land Plotting, Regulation and Building is obligatory only if required by the planning document based on which the location permit is issued. In other words, modification and adjustment of these rules to the specific location is possible in accordance with the conclusions made based on the analysis of the location possibilities during the planning process, reconciled with the higher level planning documentation. It is necessary to improve the regulation in terms of obligation to respect the specific planning and designing context, i.e. examining the effects of application of general rules on a specific planning area. Within the planning documents, there is an open possibility for including the elements which are not legally binding but can be used to the benefit of the good professional results in practice (Oliveira, 2006). This primarily pertains to

the the integrated graphic analysis (McCormack, 2013), through which different solutions of spatial arrangement can be examined and valued. In that way, the insufficiently analyzed solutions, based on overgeneralized or partial approach or one-sided interests can be alleviated, which consequently improves the quality of the built environment.

Conclusions

Theoretical solutions to the problems of relating the qualities of urban form to the planning practice in Belgrade which can be found in urbomorphological discourse of ISUF, have already been recognized in scientific investigations in the field of urbanism in Serbia (Djokic, 2007, 2009). Additionally, it is necessary to bring closer the formerly consolidated knowledge of urban morphology to the professionals in practice. By applying urban morphological methods and concepts to plans, its morphological dimension can be achieved. In the case of the Master Plan of Belgrade 2021 it implies the connection of the promoted goals of character preservation and the identity of urban areas, to typological approach to zoning (Kropf's definition). The special emphasis is given to the recommendations for improving the Master Plan of Belgrade 2021 in accordance with urbomorphological concepts which refers to defining the following: the identification of area boundaries, since the existing division of territory does not recognize the morphologically homogeneous areas in which unified building rules are applied; the key concept, since the proposed typology of residential tissue is too general and does not include important morphological characteristics of the area as the elements of the typology; the building rules, which are explicitly defined in the Plan, in the form of quantitative indicators that mostly influence building procedures.

In addition, urban morphology glossary should be accepted in order to use precise and consistent terminology in planning documents as well as in theory, thus improving the correspondence between theory and practice. Prior to introducing the morphological dimension into the planning documentation of Belgrade and real form-based approach, which can be a long-term process, urban morphology theory can contribute to improving planning practice through raising awareness with regard to the importance of interrelating the various scales of professional activities – planning, designing and building, as well as the possibilities that can be achieved by the existing planning documents. Firstly, there is a proposal to introduce plan elements that are not legally binding but contribute to foreseeing the effects of the implementation of planning guidelines in the subject area. Secondly, through education it is possible to affect the procedures for adopting plans and obtaining building permits to include the elements which are not obligatory, but are related to the quality of space that is planned and built. In these activities, the coordinative role of the professionals, i.e. of urban morphologists, is recognized, in terms of predicting future development, through coordination of planning guidelines and rules in plans of various scales.

Future urban changes through design guidance: new principles

Marichela Sepe

IRISS - National Research Council, DiARC – University of Naples Federico II, Italy.

E-mail: marisepe@unina.it

Abstract. *The urban condition we are experiencing today shows many changes in terms of the rhythms and exploitation of the city, the modalities of living, working, moving around, and the opportunities for enjoying leisure. The emergence of new typologies of place and changes in the patterns of usage for the existing typologies have given rise to whole new cityscapes: striking juxtapositions and fragmentariness seem to predominate in the wholesale dispersion with which subjects, things and habits coexist, characterised by boundaries which are transparent and yet at times unbreachable. The identity of a place, often at risk due to globalization process and rapid urban changes, expresses a harmonious balance between variant and invariant components, people and urban events, which are intrinsically linked by a reciprocal relationship that makes a specific place unique and recognizable. At the same time, public space is a topic which is increasingly assuming a new emblematic role in contemporary city and many design codes are arising accordingly. Based on these considerations, this work aims to illustrate the "12 principles for place identity enhancement", which were created from a reasoned set of blueprints for the various experiments carried out using the PlaceMaker method of urban analysis and design. The paper describes those principles and the evolution of some of these principles in the Charter of Public Space which was adopted during the II Biennial of Public Space, which was held in Rome in May 2013. The Charter includes both specific principles for place identity safeguarding and enhancement and for public space creation.*

Key Words: place identity, urban landscape, public space, urban principles

Introduction

The emergence of new typologies of place and changes in the patterns of usage for the existing typologies have given rise to whole new cityscapes: striking juxtapositions and fragmentariness seem to predominate in the wholesale dispersion with which subjects, things and habits coexist, characterised by boundaries which are transparent and yet at times unbreachable.

The contemporary city is the place not only of complexity but also of simultaneity and instability, which give rise to situations of mutation and transitoriness. These are often predominantly motivated by economic gain, to the detriment of place identity which becomes increasingly hybrid, compromised or unrecognisable.

The lengthy periods of time required for the perception of the city Kevin Lynch talks about have been altered by the acceleration of the new urban rhythms. Nonetheless it still seems true that: "City design is therefore a temporal art, but it can rarely use the controlled and limited sequences of other temporal arts like music. On different occasions and for different people, the sequences are reversed, interrupted, abandoned, cut across. It is seen in all lights and all weathers. At every instant, there is more than the eye can see, more than the ear can hear, a setting or a view waiting to be explored. Nothing is experience by itself, but always in relation to its surroundings, the sequences of events leading up to it, the memory of past experiences". (Lynch, 1960)

Undoubtedly the people and their activities are as important as the "stationary physical parts", and we are part of the scenario together with the other protagonists. "We are not simply observers of this spectacle, but ourselves a part of it, on the stage with the other participants. Most often, our perception of the city is not sustained, but rather partial, fragmentary, mixed

with concerns. Nearly every sense is in operation, and the image is the composite of them all." (Lynch, 1960)

Placemaking, in the sense of "the art of making places for people" - to paraphrase the definition given by the Cabe and Detr Ministerial Guide "By design: urban design in the planning system" - "includes the way places work and such matters as community safety, as well as how they look. It concerns the connections between people and places, movement and urban form, nature and the built fabric, and the processes for ensuring successful villages, towns and cities".

The city thus becomes the outcome of complex intersections created by a number of operators who modify the system for different reasons. It becomes necessary to identify a microsystem within the macrosystem of the city able to make the urban variants intelligible: place is at once porous and resistant, a receptor for complex interactions.

Accordingly, places are termed "places" and not just "spaces" when they are endowed with identity (Hague, Jenkins, 2005).

Such identity is related to the urban fabric and a series of morphological, natural, historical and cultural invariants. These invariants are closely interrelated to the life of the city and its inhabitants, and also to the perception the latter have of that place. At the same time, colours, materials, smells and sounds become an inseparable part of any one spot in the city, and thus emotional components of the urban image.

The identity of a place expresses a harmonious balance between variant and invariant components, people and urban events, which are intrinsically linked by a reciprocal relationship that makes a specific place unique and recognizable. At the same time, globalization and technological development have contributed to accelerating the rates of change and transforming spaces in the contemporary city. The end result is that cities, places, itineraries, customs and behavioural patterns have all come to resemble one another, contributing to an increasing urban identity crisis.

The sustainability of any place depends on a number of factors which contribute to its liveability, quality and identity (Vale, Warner, 2001; Butina Watson, Bentley, 2007; Cullen, 1961; Jacobs, 1961; Rose, 1995; Osmond, 2010).

Urban, cultural and historical poles of attraction, increasingly bear the imprint of globalization, conveying messages which have developed in an uncontrolled manner and are aimed at conveying their users' patterns of thought and action. The presence of a dense mixture of contrasting elements and perceptions can detract from the image of a city (Carter, Donald, Squires, 1993, Christensen, 1999; Castells, 1997; Nasar, 1998; Appleyard, 1981; Whyte, 1980; Urry, 1995). Furthermore, especially in pedestrian-intensive areas and in public spaces, it can contribute to creating urban decline and a chaotic atmosphere, including increased episodes of street crime. In order to draft an urban project focusing on the conservation, reconstruction and enhancement of place identity in such areas, which are often especially representative of their respective cities, we need methods of analysis and design able to identify, represent and design the urban elements that make up contemporary cities (Carmona, Heath, Oc, Tiesdell, 2010; Oliveira, 2013; Banerjee, Loukaitou-Sideris, 2010; Gospodini, 2004; Gehl, 2001).

Based on these considerations, this work aims to illustrate the "12 principles for place identity enhancement", which were created from a reasoned set of blueprints for the various experiments carried out with the PlaceMaker method (Sepe, 2006a; 2013). PlaceMaker comprises eight phases – five of analysis and three of design – and a Phase 0 that consists in constructing the grid required for the operations which are to be implemented later. This method assembles, elaborates and reconstructs the data deriving from surveys based on physical reconnaissance, sensory perceptions, graphical elaboration, photographic and video records, and sets this data against that provided by an overview of expectations, an analysis based on traditional cartography and two questionnaires administered to local inhabitants. The main products are two final complex maps, one first of analysis and one of design, which represent the place identity and project interventions in order both to establish a dialogue with local people and support planners and administrators in the sustainable urban construction and

transformation. The paper describes in section 2 and 3 respectively the method and those principles, designed as checklists for urban projects with place identity at the core. Furthermore, in section 4, it shows the evolution of some of these principles in the Charter of Public Space (Garau, Lancerin, Sepe; 2013) which was adopted during the II Biennial of Public Space (www.biennalespaziopubblico.it). The Charter, composed by 6 parts devoted to public space - definition, typologies, creation, obstacles, maintenance, management, and enjoyment - includes both specific principles for place identity safeguarding and enhancement and for public space creation. Following the Charter adoption, practical codes are in development in order to realize a Global Toolkit for public space. Section 5 draws the conclusions.

The PlaceMaker Method

The PlaceMaker method, used for the 12 principles construction, comprises eight phases. The first phase of PlaceMaker is devoted to anticipatory analysis aimed at primary investigation of places; after the preliminary choice of the city and of the part(s) to be analyzed, the ideas about that particular area can be described using any type of instrument or tool of expression, using the information known prior to the first inspection. These notes can be represented in different ways and the result of this phase will be a map of the emerging ideas.

The second phase is that of the five surveys. The first, the *denominative* one, consists in collecting data regarding constructed elements (presence of monuments, buildings, etc.), natural elements (presence of urban green areas, trees, animals etc.), transportation mode (presence or transit of cars, buses etc.), people (presence of tourists, residents, etc.). The localization of all these elements and the kind and amount, expressed as a low, medium or high percentage, are indicated. As well as the denominative data base there is a cognitive one which constitutes a kind of flexible input, where it is possible to insert elements which are not decided previously, but deduced during inspection.

The second survey is *perceptive*; a survey is carried out of the smell, sound, taste, touch and visual sensations, and of the global perception, focusing on the localization, type, amount (present in low, medium, high percentage) and quality (non-influential, pleasant, annoying). The survey of the amount and quality of the data, the three options regarding, respectively, the percentage of presence and the feelings induced, are intended to summarise the processing of data that can however be extended during collection.

The next survey is *graphical*: it consists in sketching the places; the sketches will represent the area in question according to a visual-perceptive standpoint and will be supported by annotations where necessary. This operation constitutes a preliminary study for the construction of the graphical symbols for the complex map. *Photographic* and *video* surveys of the whole study area are carried out, taking care to record facts rather than an interpretation of the places. The product of the five surveys is a map visualizing the results obtained from the different surveys.

The third phase involves the analysis of traditional cartography of the selected sites in the city. The types of maps used in this phase derive from different disciplines and depend on the nature of the place; the study is carried out at the urban scale, in order to identify the characteristic elements and their relationships with that particular area, and at the areal scale, in order to identify the relationships between the site and the whole city. The result of this phase is a map identifying the components required for the site description that can be found only through a traditional planimetric reading.

The fourth phase is that of the questionnaire administered to visitors to the area in order to gain an idea of the place as perceived by those who are not involved in the study and are not specialists in related fields, but only perceive the site as users, at various levels: the inhabitant, the passer-by, the tourist. The questionnaire consists of questions asked on the basis of images of the area or an inspection visit with the interviewee. The information deduced from the

questionnaire is transferred onto a map that, like the previous ones, will constitute the basis for the construction of the complex map.

The fifth phase is that of assembling the collected information. In this phase, we test the maps produced, the congruence of the various collected data, and choose the useful elements to construct the final map. The recorded data represent the basis for the construction of the graphical system of symbols to represent the elements of the urban landscape and the elaboration of the complex map of analysis (Sepe, 2006a).

We then have three design phases. The sixth phase is devoted to surveying identity resources in the study area. During this phase, the complex map of analysis drawn up with the PlaceMaker method is used as a basis to detect the resources available for the project.

The sixth phase is realized through three measures. The first is the identification of the identity potential, namely of the elements of the complex map which characterize the area in question in order to recognize those which may assume a focal role in the project. In this respect, both the comprehensive presence of a specific type of element (e.g. how many points of visual perceptions are present) and the quantity is measured for each of them (e.g. such an element is assigned a certain size of symbol depending on its visual importance: namely medium size=presence of a given element in a medium percentage). Then there is the second action where the identity problems are highlighted. The activities are devoted to observing places in the complex map with the presence of unsustainable elements and annoying points of perception. With the aim of identifying these places the relationship among the different elements in the map need to be observed. An element may be sustainable in itself, for example a shop which sells typical products; but the presence of several of them may create a site with a concentration of businesses which is unsustainable with respect to place identity. The goal is to understand the impact of people, things and activities and relative issues. The third action is the survey of identity qualities.

The actions to be performed here involve noting places within the complex map of analysis with the presence of sustainable elements and points of pleasant perception. The elements which contribute to defining that sustainable place or perception will need to be analyzed. In this case the aim is again to detect the impact of people, things and activities and relative relationships which are sustainable for identity of places. The product is a synthesis derived from interpreting the complex map of analysis where the identity resources available for the project are represented: a sort of map of intents, the first step for the construction of the complex map for the identity project in question.

The seventh phase is the survey of the identity resources by users of places, locals, passers-by and tourists. A questionnaire designed to elicit information emerged from the previous phase will be administered. The questions aim to ascertain whether the data observed until now are consistent with aspirations, desires and thoughts of the users of the area in question and to collect further suggestions and proposals. The product of this phase is the fourth partial map which will represent the identity resources from the perspective of users of places and/or privileged actors.

The eighth and last phase consists in the overlay of data collected during the previous four phases and identification of the project proposals. In this phase we identify the places around which the project hypothesis to be conducted to enhance the identity resources are focused and the relative interventions. The products of this phase are a suitable system of symbols which represent the project activities and the construction of the complex map for the identity project. This map is the last step in the planning process, where the information contained in the complex map of analysis, after being filtered and transformed into resources, gives rise to proposals for the construction and enhancement of a sustainable place identity (Sepe, 2013).

The method has been experimented in urban sites in Europe - Barcelona, Helsinki, London, Berlin, Lisbon, Paris, Wien, Rome -, Asia - Kobe, Beijing, Xian -, and USA - Boston, San Francisco, Los Angeles - (Sepe, 2010; 2006b; 2009). The main users targeted by the method are urban designers and planners, and administrators, while a simplified form of the complex maps is designed for local, citizens, place users and visitors.

As regards administrators and city planners, PlaceMaker enables them to understand the potentials and problems relating to any given place, and how the place itself is perceived by its users and residents. This flexible method may be used for different analysis and design purposes, such as: to redefine the identity and image of a place or a public space (e.g. historical identity, commercial identity, identity following post-seismic reconstruction etc...), to assess - and then design - the compatibility of any activity with its identity or again, if the aim is to restore traditional businesses, to gauge whether such recovery is still in line with current demands (e.g. in case of urban regeneration process). Thus, the data contained in the complex maps may be used to create active indices and reference parameters for gauging project sustainability, such as quality of life or pollution thresholds, or sustainability of identity, through assessment of the elements making up urban identity from the viewpoint of sustainability.

As to the citizens, PlaceMaker will enable them to garner a deeper understanding of their city's identity, feel stronger ties to it, hence protect and safeguard it or play a proactive role by proposing improvements to administrators or participating in planning choices.

Lastly, tourists and place users will find the map a tool providing an insight into the city and its public spaces that goes beyond mere identification of major landmarks and captures the complexity of a place identity, including its tangible and intangible elements, both permanent and temporary.

In order to study the urban identity of sites and identify new elements and places, the areas selected for the experiments and which were used for the 12 principles construction are mostly of historical importance and at all events highly representative of the city and of its transformations, alterations and redesign themes.

12 principles for place identity enhancement

The case studies gave rise to 12 principles for place identity enhancement, created from a reasoned set of blueprints for the various experiments carried out using the PlaceMaker method (Gehl, 2010; Jones, Marshall, Boujenko, 2008; Sepe, 2012).

1. Identity resources of a place have to be protected and enhanced so as to give the place in question a distinctive character.

In order to counter the standardization of places which tends to make sites increasingly similar to one another, it becomes ever more necessary to protect identity resources. A site should have elements which make it unique and recognizable. In order to be sustainable, an urban project must be integrated with the identity of places.

2. Place identity has to be determined with ad hoc methods.

Place identity is a complex concept that requires identification of the various factors and elements which make up a place. There are many such elements forming place identity, increasingly compromised by the acceleration of urban change and globalization. In order to make identification as thorough as possible, *ad hoc* methods have to be used both to detect such complexity and specify guidelines for design.

3. Attention to context is to be understood from a social, environmental and urban perspective.

The context of a place has characteristics not only related to its architecture, urban form and culture, but also to the people who live there, and its environment, understood as natural resources. For sustainability in its broadest sense, respect of all these components is required.

4. The maintenance of buildings, roads and public spaces should be programmed.

Roads and public spaces have to be maintained in the same way as buildings. Programmed maintenance should be performed periodically in order to ensure constant quality of public spaces as well as buildings within.

5. Places should perform functions which do not cause intensive use that can damage site quality.

Monofunctional uses can cause damage to place identity. An example of this is the case of pedestrian thoroughfares of historical importance, used only for business. Combined uses of places should be aimed for, provided they do not compromise place identity.

6. Local businesses should be enhanced.

The intensive use of sites by mass tourism leads to businesses that result in rapid consumption of places at the expense of their culture. It is instead necessary to promote local businesses to ensure residents put down roots where they live.

7. Users of a site should be questioned about place identity during both the survey and design phases, taking different needs into account.

Site users, the prime recipients of urban transformation projects, should be interviewed at various stages in the transformation process of an area, with particular attention to the identity of the place in question. The project will thus be more likely to succeed since various needs will have been taken into consideration.

8. Place identity should be monitored periodically.

Given the great acceleration of the rate of urban change, it is important that place identity be periodically monitored in order to understand evolution and change in time and prevent identity being compromised.

9. Vehicle use in areas with heavy pedestrian throughput should be avoided or slowed down.

In emblematic thoroughfares, public spaces and historical centres the use of private vehicles is an annoyance factor. In this respect, in such places vehicle speed should be slowed down with appropriate traffic calming measures, or private vehicles should be banned altogether. The use of bicycles and dedicated lanes should where possible be encouraged.

10. The safety of users is paramount.

The users of streets and public spaces in general need to be protected. In this respect, projects should ensure safety both as regards possible collisions with vehicles, with appropriate separation between the different types of flows, and as regards possible criminal acts, encouraging mixed uses of the places in question during the different times of the day.

11. Proper enjoyment of the physical characteristics and natural beauty of the place should be considered a priority.

We need to create places which foster the enjoyment of the elements that make up the history and culture of the place through projects which stimulate knowledge and sustainable use. By the same token, it is necessary to promote the enjoyment of all natural resources which are part of that place.

12. Respect for place identity should be considered a sine qua non within the framework of a project's quality requirements.

Respect for place identity lends quality to a project. Place identity should thus become an essential aspect of urban planning tools so that it becomes a fundamental requisite for project sustainability.

The charter of public space

The Charter (Garau, Lancerin, Sepe, 2003), which was adopted - as mentioned in the introduction - during the II Biennial of Public Space, which was held in Rome in May 2013 (www.biennalespaziopubblico.it), is composed by 6 parts devoted to public space, namely: I. Definition of Public Space; II. Typologies of Public Space; III. Creation of Public Space; IV. Management of Public Space; V. Enjoyment of Public Space; VI. Obstacles to the Creation, Management and Enjoyment of Public Space.

The main criteria this document is based on are that a) it is useful to formulate a clear and comprehensive definition of public space, b) that public space should be regarded as a public good, c) that the Charter should contain reasonable and shared principles with regard to the conception, the design, the realization, the management and the enjoyment.

The principles which were before described were used as a contribution for the creation of some principles of the Charter, including those which follow.

Definition of Public Space

Public spaces consist of open environments (e.g. streets, sidewalks, squares, gardens, parks) and in sheltered spaces created without a profit motive and for everyone's enjoyment (e.g. public libraries, museums and eco-museums). Both kinds of places, by virtue of possessing a clear identity, can be defined as "places".

Public spaces, whenever safeguards of natural or historical beauty allow, must be made accessible without barriers to the motorial, sensorially and intellectually handicapped.

Typologies of public space

It is opportune to distinguish public spaces in: a) spaces that have a prevalently functional character; b) spaces that presuppose or favour individual or atomized uses; c) spaces that, by mixing of functions, form, meaning and especially in the connection between the built/non-built, have the prevalent role of aggregation and social.

Public spaces:

- b) Host activities of the market and make accessible commercial activities in fixed premises, public venues and other services (collective and not, public and private), in which the socio-economic dimension of the city is always expressed.
- c) Offer precious opportunities for recreation, physical exercise and regeneration for all (parks, gardens, public sports facilities);
- e) Are places of individual and collective memory, in which the identity of the people is mirrored and finds sustenance, growing in the knowledge that it is part of the community;
- g) Are an integral and meaningful part of the urban architecture and landscape, with a determinant role in the overall image of the city;

Management of Public Space

Reducing private automobile traffic in cities is a primary condition for improving environmental conditions, enhancing public spaces and making them more liveable.

In terms of the area they cover, streets, squares, sidewalks constitute the overwhelming portion of the urban space used by the public. It is therefore important for their use to be disciplined to reconcile the different functions they are to perform, granting priority to pedestrian and non-motorized mobility.

It is important to adopt policies that encourage the permanence of artisans and neighbourhood shops, which contribute to the quality of life and to the animation and vivacity of daily-use public spaces.

V. Enjoyment of Public Spaces

- 41. All citizens, regardless of their role, are users of public space. All of them have the right to access and enjoy it in complete freedom, within the rules of civic coexistence. In cities ever more complex and diverse, this requires democratic processes, dialogue and regard for diversity.
- 44. The enjoyment of public space is a fundamental ingredient for determining and applying indicators of the quality of public space, to be employed throughout the entire creation-management-enjoyment cycle.

VI. Constraints on the Creation, Management and Enjoyment of Good Public Spaces

48. The following can be considered constraints on the creation, management and enjoyment of good public spaces:

a. The commoditisation of urban sociality (such as the proliferation of specialized facilities for shopping and leisure, private sports facilities, etc.);

Conclusion

The paper presented the 12 principles for place identity enhancement, which were created from a reasoned set of blueprints for the various experiments carried out using PlaceMaker method for the analysis and design of the contemporary urban landscape. The PlaceMaker method derived from the need to identify the elements and places that are the components of contemporary identity, many of which do not figure in traditional cartography, and to identify principles for their planning and enhancement. The flexibility of the PlaceMaker method enables it to be used in widely varying contexts and for a range of objectives. The investigation protocol can serve as a guide to be adapted and reinforced at some points, according to the characteristics of the place and the intended purposes.

The innovative aspect of this method consists, on one hand, in the integration of different modalities and instruments for obtaining the information required to render objective and measurable even those elements which are subjective and ephemeral, and on the other hand in exploiting the complexity of the data obtained to construct the planning guidelines.

Accordingly, the purpose of the 12 principles is to provide urban planning guidelines for the construction and enhancement of sustainable place identity. The concept of identity is interpreted in line with the definition of Kevin Lynch who refers this concept to the set of characteristics which make a place unique and recognizable.

Although the concept is intended as a set of characteristics in a positive sense, it is also possible that these features are not sustainable or are not consonant with the history and culture of the place itself. Indeed, the set of characteristics may consist, for example, of the shops whose furniture disfigures the ground floors of buildings and prevents appreciation of an urban thoroughfare, but which make that location recognizable. A further example might be the set of elements in a public space which makes that place distinctive but which people in that neighbourhood do not use since it fails to give them a sense of belonging.

The 12 principles aim to provide a check list which a project has to satisfy in order to enhance the identity of the place in question, making sure, however, that place identity is sustainable and is not used for the sole purpose of rapid consumption of intangible heritage. The principles should not be considered static, but dynamic, in keeping with the increasingly rapid rates of change in a place that continually lead to expanding the scope of the concept. These principles in their present form may thus be constantly updated to allow not only for changes in the contemporary city but also for new procedures and requirements in site design.

The principles were used as a contribution for the creation of some principles of the Charter of Public Space which were described in the Charter section of this paper. The whole Charter is composed by 50 principles. The Charter is now in course of further development and transformation in a Global Public Space Toolkit by Un-Habitat and INU, the Italian Planning Urban Planning Institute.

The paper, with the description of both principles, had the final aim to demonstrate the importance of the use of scientific approach to the creation of urban design guidance. Public spaces are a topic which is increasingly assuming a new important role in contemporary city and many design codes are arising accordingly. It is important approaching it with both care and rigorous method in order to obtain suitable and sustainable results able to tackle at the same time the challenges offered by globalization and different kinds of crisis.

Abstract. *Within the political context of Switzerland, the contemporary debate on urban morphology has to become central to the implantation of state-wide policy that focuses on the limitation of urban sprawl. This is particularly emphasised because the legal framework focuses primarily on landscape protection rather than on urban development strategy. In fact, if urban sprawl has been a real threat for Switzerland's small territory and attractive natural landscape since the 80's (DFI, 2009), the corollary urban densification within already urbanised areas is threatened by a rejection by the citizens, through legal referendums, primarily triggered by an misunderstanding of the morphological consequences of density targets. In particular, citizens frequently overlap "densification" with "towers". A central challenge to the public planners of the township's association of Morges is then to establish a public communication strategy on the importance of the densification of urban cores, focusing in particular on the relation between density, urban morphology and urban quality. In collaboration with a private consultant office, a comparative analysis on density, urban form and quality of life relying on local case studies has been made, completed with numerous participatory actions aimed at shifting the focus from legal density targets to a shared discussion and debate on the qualitative attributes of neighbourhoods. Local workshops, exhibitions, a website, a booklet and local newspapers publications are among the supports of this communication campaign for decoding the quality and versatility of swiss urban forms. Once the foundation has been laid, we expect to achieve a horizontal dialogue with citizens and developers about the quality of their neighbourhoods in a day-to-day basis and avoiding density numbers and misperceptions. Our practical experience, methodology and results achieved so far with this process are described as well as our ambitions on how the project can evolve and constitute a bridge between theoretical and participatory urban morphology research.*

Key Words: density; public participation; quality of life; urban form; urban practice.

Density, Urban Form and quality of Life

As it has been highlighted by the recent modification of the federal law on land use planning (federal vote of March 3, 2013), densification has been for many years one of the main objectives of the land use planning policies in Switzerland. Formalized as a constitutional principle since 1969, the concept of densification has since then progressively been implemented in the many laws and processes regulating land use.

Being one of the pillars of the federal policy on agglomerations, it has served as one of the guiding principles of the Lausanne-Morges Agglomeration Comprehensive Plan (PALM), within which Region Morges (RM) is one of the districts. Indeed, within the urban growth boundary that has been defined through the PALM, a minimal density of 100 hab. or empl./ha (residents+jobs/ha), equivalent to an FAR of 0,625, has been defined for all future planning. That minimal density is raised to 200 residents+jobs/ha, or a FAR of 1,25, within the boundaries of the strategic areas of the plan.

However, despite having been accepted by the majority of Swiss citizens, mainly on the grounds of protecting the landscape, densification is not well understood, and even fought at the local level: diminishing quality of life, destruction of the last remaining city open spaces, increase of pollution, land speculation, or abandonment of the suburban ideal of the countryside villa, the concentration on the development within the perimeter of the agglomerations, heavily

promoted at the federal and state level, has been made difficult to implement because of regular opposition by local stakeholders groups and citizens.

It is then critical to the success of the planning policies that the notion of densification is well understood if one wants to curb the lack of housing availability, and to manage the population growth in Switzerland while implementing the overarching goals of protecting the landscape and managing resources. This is particularly true in Switzerland, where a unique participatory democratic process allows the population to participate directly to the public legal and regulatory process, and in particular on matters of urban planning and design, through the ability to organize referendums. Within the perimeter of the PALM, many projects have suffered from a lack of understanding of basic notions regarding density, in particular as it had a tendency to associate a specific urban form to density targets, or to associate the debate on density with a debate on highrise buildings. That confusing and relatively sterile debate had the corollary effect that the themes of urban quality and experience have singularly been missing from the conversation. Thankfully, the notion that density is necessarily associated with a loss of quality or with specific urban forms is misguided, and quite to the opposite, densification can be a powerful tool to increase the quality of urban life and experience.

Through a series of examples and a review of the basic planning literature, Region Morges aimed to show through a carefully managed public outreach program that densification is not only a necessity but also an opportunity to debate on the multiple environmental and urban qualities that can be achieved at the 200 residents+jobs/ha target that has been defined at the regulatory level.

What would Region Morges have become if...

The first action of Region Morges was to create powerful images to create surprise, interest and discussion with the population. It was also a way to highlight the correlation between landscape protection, one of the primary goals of the popular vote of March 3, 2013, and its counterpart, the densification of the urban centers. Different development scenarios for the Region Morges have been devised in order to be compared to the current situation:

The first scenario illustrates what the Region could have become if the current population would have been accommodated in a typical suburban sprawl development pattern (single-use residential areas, and office parks along the highway exits) ;

The second scenario illustrates what the Region could have looked like if the current population would have been accommodated in a typical traditional urban pattern, as it can be seen in the historic core of the city of Morges (FAR 3): a contiguous and mixed-use urban pattern, organised along narrow streets, with a typical building height of 3,5 stories.

Extremely realistic city maps were drawn to illustrate each of the scenarios. They were posted on the website of Region Morges, and published in the local press to announce an exhibition on density and quality of life.

Apart from the "shock" generated by the comparison of the illustrative plans, the results of this exercise were also quite telling. The built environment of the Region Morges occupies today 925 ha. However, if at the beginning of the century, the logic of dense urban development had continued, the built environment would only span on 7 times less space, which would mean that a very significant area would have been preserved from urban development, and could have been used for leisure, recreation or more conservation and agricultural production. If instead we all chose to live in villas, we would be dealing with an area increase of 60%. The current situation is therefore much closer to the suburban model than to the traditional pattern of the city of Morges.

Figure 1. Urban footprint of Region Morges. To the left, the current situation, in the centre, the first scenario (suburban pattern), and to the right, the second scenario (traditional urban pattern).

Why should we densify?

Once the discussion had started, it was necessary to formalize with more specific arguments what were the planning benefits of densification. Densification is seen today as a necessity to preserve the landscape and natural resources, but the corollary densification of the urban cores, contrary to the popular belief, can also benefit from the resulting intensification.

Preserving the environment and the landscape: a well understood concept

The popular vote for the new federal law on land use planning was a clear sign that the Swiss people wanted to protect the landscape. It was however necessary to explain in more formal terms why it would be so.

Landscape under stress

The landscape is a fundamental element of the identity of a place or region. Including both "natural" components such as the topography and subtle articulation of wooded area, rivers and agricultural components, and "historic" and cultural components such as old farms, villages or cities, the landscape of a region shapes its inhabitants who are very sensitive to the preservation of its characteristics.

Urban sprawl, i.e. the dissemination of buildings over a wide area, causes significant land consumption for the construction of housing and infrastructure at the expense of natural, agricultural and viticultural areas. This rapid transformation of the landscape erases the legacy of the past and fundamentally negates the perception of the landscape by the inhabitants of the area.

Although primarily an emotional concept, the landscape has a great influence on the individual and collective perception of quality of life. It is therefore necessary to take it into account in order to preserve the area's identity .

Biodiversity under stress

One of the leading causes of biodiversity loss comes from the fragmentation of natural habitats, i.e. interruptions between connected ecosystems. Biodiversity is important to humans because it

guarantees the resilience of our environment. The more animals and plants living in the same environment are numerous and diverse, the more they will be able to withstand external events such as pollution, temperature change or natural disasters. Less diverse environment, once under extreme situations, degrade very quickly and recover a balanced state only after many years.

The construction of a dispersed urban pattern requires the construction of an extensive road infrastructure that often consists of an insurmountable barrier for most species. Subsystems that once evolved in synergy now find themselves completely dissociated. They become favorable to only a small number of specifically adapted plants and animals while most of the others will disappear gradually. The construction of a dispersed urban habitat is one of the key factors causing the general impoverishment of biodiversity.

*Statistic sources are in the origin of this simulation. Results may vary based on location, species, traffic volume, etc.

Figure 2. Landscape fragmentation and species probability of survival. Transportation networks cause an increasing partition of the large biodiversity reserves (source : Figure modified by Jaeger and Holderegger, 2005/ OFS).

Figure 3. Transportation networks decrease the continuity of biodiversity networks.

Land use conflicts

Historically, agriculture was the key factor that enabled the development of cities. The fields on the outskirts of the city produced foodstuffs needed to feed the urban population. Even today, any agglomeration automatically require some agricultural land to feed its population. Although today, due to the phenomenon of globalization, the Swiss cities are more dependent on foreign goods for their livelihood, local agriculture is nonetheless highly significant both for its production of local goods, and to guarantee the long term maintenance of natural areas. Causing a decrease in available agricultural land, urban sprawl reduces the viability of farms and thus contributes to the progressive dismantling of an essential profession, both for the survival of cities and for the maintenance of the environmental framework.

Figure 4. Land use changes in Switzerland (regions of Grisons and Tessin non included)
(source: OFS).

Infrastructure costs and mobility

By encouraging the use of private vehicles to meet the mobility needs, a more dispersed habitat causes an increase of cars on the roads, which leads to congestion and air pollution in and around the agglomerations .

When the housing units are highly scattered, the establishment of an attractive and efficient network of public transport is indeed not possible. Because of that, the only alternative to get to work or to carry out any activity is to use the individual car, thereby increasing the number of vehicles on the road, kilometers traveled and air pollution.

Densification to improve public transportation

By encouraging the use of private vehicles to meet the mobility needs, a more dispersed habitat causes an increase of cars on the roads, which leads to congestion and air pollution in and around the agglomerations .

When the housing units are highly scattered, the establishment of an attractive and efficient network of public transport is indeed not possible. Because of that, the only alternative to get to work or to carry out any activity is to use the individual car, thereby increasing the number of vehicles on the road, kilometers traveled and air pollution.

Costs optimization

In addition to the environmental problems it generates, urban sprawl requires the construction of a large transportation and infrastructure network to connect all habitations. By limiting urban sprawl, densification reduces the cost of construction and maintenance of such networks for both public authorities and individuals.

If the democratization of the automobile and the improvement of transportation networks have fundamentally changed the way of life since the beginning of the century by reducing the time required for travel, it has also allowed to expand the settlements further and further away from the workplace, allowing to benefit from a certain quality of life, or from advantageous fiscal conditions, in the countryside while maintaining his workplace in large urban centers.

This pattern generates nevertheless many problems as the expansion, construction and maintenance of kilometers of roads, pipelines or electric network needed to connect the most remote hamlets weight increasingly on finances public authorities. The latter, in high demand in many areas such as health, social or education, often have no other choice but to reduce their benefits or to borrow at the expense of future generations.

Figure 5. Long-term marginal costs of different urban development forms (source : ECOPLAN, ODT).

Figure 6. Average costs of infrastructure of different urban forms (source : ECOPLAN ODT)

Mobility is, like telecommunications, one of the foundations of our current ways of life. Every day we go through dozens, hundreds of kilometers to get us on our workplace, our leisure activities, to visit friends, to discover new places or even for the sake of travel. The feeling of freedom that provides the ability to move without being limited by the distance is undeniably an important element of quality of life. But whatever the system of transport, mobility also has both financial and time implications.

Suburban sprawl, where most of the population lives far from his workplace every day, generates important commuting costs, both in terms of car ownership, and in terms of time spent in traffic, that weigh heavily on the household budget. In addition to the visible costs such as the costs necessary for the construction and maintenance of infrastructure or for fuel used during travel, road transport also generate many nuisances that result in hidden costs to the community.

Road accidents, damage to health due to pollution and environmental damage are some examples of costs directly related to the transportation system and supported by public finances. Each year these nuisances generate several billion francs in externalized costs borne by society.

Figure 7. External costs of road and rail transportation in 2009 (source : ARE)

Density is not contradictory to quality of life

Finally, the most widespread misconception remains the supposed antinomy between density and quality of life. To the opposite, Region Morges wished to demonstrate that the densification was a unique way to fulfill the diversity of lifestyles and expectations of the population for their housing choices.

By limiting distances and offering a diverse and efficient transportation system, densification allows to freely choose the most appropriate transportation mode according to its needs, as well as an easy access to a wide variety of goods and services. It thus promotes the autonomy and independence of people who do not have a motor vehicle and offer a choice to everyone.

A lack of transportation choices

Mobility needs in the periphery make the acquisition, maintenance and use of a private vehicle almost indispensable. Indeed, a low density urban environment severely limits the opportunities to build a network of efficient public transport, and the relatively large distances between the points interests discourage the biking or the walking patterns.

A lack of local commercial or services offering

Suburban developments makes it hard for small businesses local services to survive. As most potential customers must necessarily drive to get to shops because of long distances, they generally prefer to go directly to larger shopping centers, destroying any chance of survival of a more diverse commercial ecosystem. The range of choices becomes monocultural and of average quality.

A lack of cultural and public amenities

Access to services and public amenities such as schools, nurseries, postal services, playgrounds, sports facilities, hospitals, theaters and cinemas most often requires, due to distance, to dispose of a motorized vehicle. This configuration limits the autonomy of people do not have a vehicle, like children, adolescents and older people in particular.

Figure 8. Average distance to the nearest local service in 2001 (source : OFS, 2006 – Services to the population : accessibility 1998-2001)

Density and urban forms

These basic clarifications on the concept of density helped to initiate a shift in the debate on more specific subjects than the usual discussion on the supposed merits of particular FAR or human densities, to initiate a more productive conversation on the qualities of particular neighborhoods.

The densification targets that have been defined in the comprehensive planning tools for Region Morges will in fact leave a very wide choice as to the form of neighborhoods to achieve. Many examples from Morges Region demonstrate the possibility of relatively dense neighborhoods, perfectly in line with the density targets, that are recognized as highly qualitative by the inhabitants of the region.

Where and how will we densify?

Identification of target zones for densification: the “compact perimeter” and the “strategic sites”

In order to promote the densification process, the Lausanne-Morges Agglomeration Comprehensive Plan (PALM) has targeted the expected population growth of the region within the “compact perimeter”, an area consisting of 26 municipalities including, within Region Morges, the municipalities of Denges, Echichens, Echandens Lonay, Lully, Morges, and Préverenges Tolochenaz.

The objective is to accommodate, within this perimeter, 69,000 new residents and 43,000 potential new jobs by 2030. This means that the “compact perimeter” will welcome 83% of new residents and 94% of new jobs of the whole agglomeration. Within this perimeter, some areas with major strengths such as good accessibility by public transport, have been identified as “strategic development sites”. Because of their many advantages, strategic sites are considered a priority for the densification.

Region Morges region includes two strategic sites:

- The site H1 that spans on the municipalities of Denges, Lonay, Morges et Préverenges;
- The site H2 that spans on the municipalities of Morges et Tolochenaz.

By themselves, these two “strategic sites” have sufficient potential to accommodate between 10,800 and 12,200 people and jobs.

Density target

The legally required density targets are measured in terms of people and jobs per hectare (habitants+jobs/h). For simplification, it considers that a person who works at a place generates

the same travel needs, and therefore the same road infrastructure and public transport network, than a resident.

Minimum densities required are based on some typical densities observed today in the Region:

-100 residents jobs per hectare (residents+jobs/ha) within the "compact perimeter", which corresponds today to zones of low to medium density;

-200 residents jobs per hectare (residents+jobs/ha) within the "strategic sites", which corresponds today to zones of medium to high density;

The objectives are thus to promote a low to medium density within the compact perimeter and a greater density within the strategic development sites.

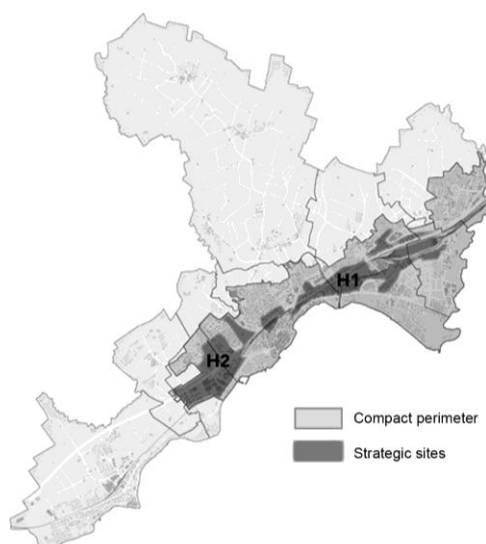

Figure 9. Compact perimeter and strategic sites of Region Morges.

Analysis of 25 existing urban forms

The legally required density targets defined by the PALM only marginally restrict the choice of neighborhood shape and form. Indeed, of the 25 urban forms analyzed:

- Only 6 do not meet the minimal density targets (less than 100 /ha)
- 12 are dense enough to meet the minimal requirements of the "compact perimeter" (between 100 and 200 residents+jobs/ha)
- 7 are dense enough to meet the minimal requirements of the "strategic sites (200 residents+jobs/ha and above)

Thus, contrary to a common public complaint, the density targets of the PALM do not necessarily equate to something that is foreign to what already exists within the existing built environment.

In other words, even if these are only examples, they illustrate the wide range allowed by the density targets, both in the neighborhood patterns, and in terms of building heights.

Relationship between density and building height

A higher density does not necessarily mean building towers! Among the seven examples with the highest density, the average number of stories varies significantly (between 3.4 and 10.7 floors). Also, a low density does not necessarily mean more green spaces.

Density: 100 à 200 residents+jobs/ha

In the region, a big diversity of urban blocks typologies with an average density can be found both in the form or in the height of buildings.

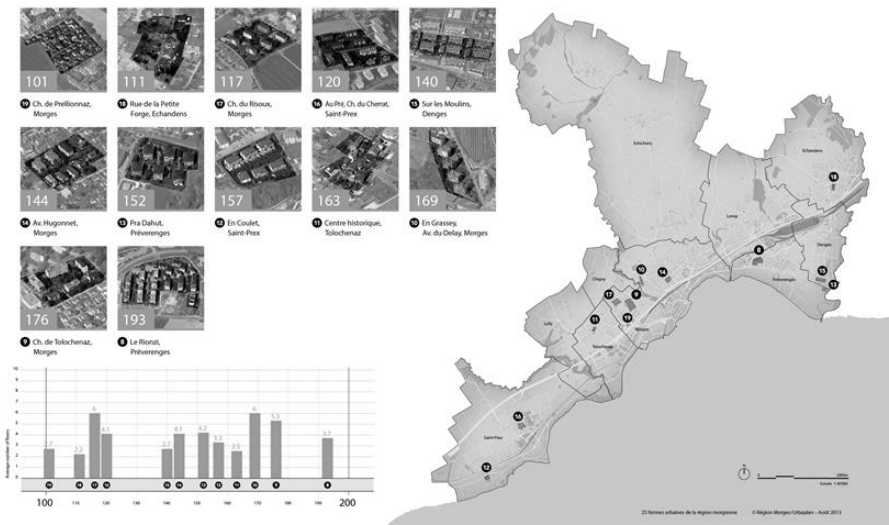

Figure 10. Twelve urban blocks reaching the target density for the “compact perimeter”.

Figure 11. Average number of floors by urban block and density (residents+jobs/ha).

Figure 12. Several possibilities of urban typologies with the target of 200 residents+jobs/ha.

Relationship between density and quality of life

The density does not necessarily impact on the quality of life! Other factors linked with the climate, or the spatial or personal understanding of the environment play a more important role in the perception of quality.

Quality of life within an urban environment

Although the perception of a neighborhood is unique to each individual, planning has an extremely important role for the establishment of the framework conditions affecting the quality of life.

What is quality of life?

The quality of life is undeniably a subjective notion. It depends heavily on personal and cultural representations of each individual, their history and their relationship with their surroundings. However, because of the direct impact on the shaping of the territory, urban planning has a structuring effect that strongly influences our perception of our environment. A reflection on the multiple ways of perceiving urban quality therefore seems essential to enable the realization of favorable developments, not as a dogmatic pursuit of goals to align and standardize behavior, but rather to understand the expression of the diversity of lifestyles in contemporary society. Through an understanding of the different activities that we practice daily in the city, and by structuring the issues at stake at the neighborhood and at the regional level, urban planning and design work helps to promote a qualitative densification for the benefit of the entire population. Some of the key categories allowing an understanding of the neighborhood qualities are described below.

Figure 13. Example of quality analysis of a high density city block.

Consider multiple uses of the public spaces

In a dense environment, a wide variety of activities can potentially happen in the public spaces and should be taken into account when defining the characteristics of these spaces.

Public spaces, in contrast to the private areas, must offer every individual an opportunity to make its own activities without encroaching on the activities of others. Depending on the specific objectives of the neighborhood development, it will be necessary to consider the various possible uses and to integrate them into the space design.

A street, for example, should not be just considered as an axis of movement, but also as a living space where a number of activities can happen. Depending on its location and its relationship with adjacent neighborhoods, a street may be dedicated mainly to vehicles, or instead multiple uses such as walking, shopping, meeting, relaxation or to host events.

Adapt design to environmental conditions

Access to sunlight contributes greatly to our quality of life, which does not prevent us to enjoy some shade during the summer months. Whether wind, rain, temperature, or noise, the built and natural environment may alternatively provide a shelter or a welcome release to take advantage of climatic and seasonal conditions. The inclusion of these criteria in the process of development can result in the creation of environments that are comfortable in all seasons and that will be naturally welcoming to public uses.

Care for the transitions between spaces

The proximity between private and public spaces, between spaces dedicated to relaxation and activity, or between spaces dedicated to circulation and playground areas, can be a source of many conflicts that must be managed by more or less rigid urban transitions.

Although often considered as a default solution, strict separation such as walls, car parks or hedges are not always best suited. They are indeed a response that prevents any opportunity for dialogue and relationship to happen between the different areas constitutive of the urban realm.

Encourage local services and amenities

The development of a complex and differentiated society like ours offers the opportunity to enjoy a multitude of goods and services. The possibility of having, near his house, a playground, a nursery, a school or a grocery store, can be extremely convenient for residents. Other types of activities, such as specialty shops, stadiums, theaters or other large infrastructure should instead be located close to the urban centers to ensure access for all residents.

Facilitate the permeability of neighbourhoods and the freedom of movement

The ability to easily navigate in a dense environment is fundamental to preserving the feeling of freedom. Pedestrian paths and bike should be part of all built environments as they help to promote a public perception of space. The creation of "permeable" neighborhoods, in the sense that they can easily be passed through on foot or bike, is important to promote a high quality of life for both residents and for bystanders.

On the opposite, because of the pollution they generate, motor vehicles should be kept away from some residential areas and concentrated on main thoroughfares.

Remember the visual delight

The visual quality of a building, a neighborhood or a natural landscape is a matter of personal perception. However, urban planning and design can help create a delightful environment, by

taking into account different aspects, such as the harmony of the architectural composition or the visual transitions between spaces, or the staging of landscape vistas.

The landscape vistas in particular, because of the specific views they frame, reinforce the sense of belonging to the region in which we live and work, while the architectural composition and character defines the atmosphere of a neighborhood and promotes the emergence of a certain mindset.

Confrontation of the analysis -dialog with the local residents and population

To complete this analysis of the quality of life in urban areas, it was also necessary to confront this technical approach to the sensible experience of the residents of the area and of the studied neighborhoods.

An open discussion with the residents

In partnership with the local press during two months, one neighborhood a week was put "under the microscope" in an dedicated article. These articles synthesized the analysis that had been made by Regin Morges and its consultant Urbaplan, and completed it with interviews of actual residents. The selected neighborhoods were all representative of a density equal to or above the target density of the regional comprehensive plan (PLAM), yet none of remarks of the inhabitants were about the height or the perceived density of buildings. All were talking about the proximity to public transport, shops, entertainment, views, public spaces, vegetation, etc. These interviews confirmed that the analysis of neighborhoods using a qualitative approach was more appropriate and closer to what the residents felt than a debate on abstract figures and density ratios. In addition, we found that the opinion of the inhabitants were generally very close to the sensible appreciation of the neighborhoods made by the professionals, regardless of the density.

The general public reactions

The last step of the process concluded with a public exhibition on "density and quality of life" in Region Morges. In addition to the three land use scenarios, and the description of the planning advantages of density from a public policy point of view, six contrasting density neighborhoods were presented, illustrating various shapes and densities:

- One single-family villas neighborhood in Lonay, with one-storey high buildings surrounded by a private garden. Average density: 36 residents+jobs /ha.
- One neighborhood composed of six single-standing buildings, 3 storey-high with attic, scattered on a vast open and landscaped garden. Located in St Prex. Average density: 157 residents+jobs /ha
- The traditional village center of Tolochenaz. Comprised of 2,5 storey-high contiguous buildings lined up along a central narrow street. Average density: 161 residents+jobs /ha
- The "Uttins" neighborhood in Préverenges, with a density of 210 residents+jobs /ha. Based on a village structure, it is characterized by buildings of 3 stories + attic. Organized around a large communal space, it is generously landscaped. The architecture is characterized by fairly homogeneous buildings, articulated through changes of shapes and opening of vistas towards the surrounding agricultural area.
- The "Pre-Maudry" neighborhood in Morges, with a density of 227 residents+jobs /ha. Given the height of buildings (8 floors) this density is interestingly low. This is due to the generosity of the large outdoor spaces open to the farmland. The architecture is very simple and the landscape echoes the great scenery surrounding the neighborhood: lake view and farmland.
- The historic center of Morges, the most dense area of Region Morges at 475 residents+jobs /ha. The buildings are 3 floors + attic and are contiguously aligned along narrow streets. The

larger shopping street that crosses the middle of the neighborhood, the immediate proximity of the banks of the lake and of a large sports park make this an extremely pleasant neighborhood.

Visitors were invited to comment on neighborhoods with post-it. None of the comments showed a lack of appreciation of the denser neighborhoods. Quite to the contrary, the most positive opinions have often been given on the densest neighborhoods: the Uttins neighborhood and the historic center of Morges, both being praised for their friendly atmosphere, close to shops and services and the size of communal spaces. On the other end, the least dense neighborhood left an impression of sadness.

If it is not possible to conclude at this stage that denser neighborhoods are the most popular, it has nevertheless been shown that a shifting of the debate from the hard numbers of density, to the qualitative elements of a neighborhood while explaining in simple terms the overarching goals of the urban densification policy, allows a much more nuanced and positive debate on the subject.

Study on relationship between urban morphology and policy in China

Caixia Gao, Wowo Ding

School of Architecture and Urban Planning, Nanjing University, Hankou Road 22, Nanjing 210093, Jiangsu, China. E-mail: ggcx1977@gmail.com, dww@nju.edu.cn

Abstract. *Urban form might be described as the result of numerous shaping processes in varying social layers at a given place through time, especially from the power of internal and external economic development and urban policy control. Moreover, urban policy plays very important role particular in China in terms the proprietorship of the land. Therefore, the morphological description is indicative of the different academic disciplines that engage in urban morphology, surely should include the urban policy. Focusing on urban policy in China our project has investigated in urban policy in the State level, provincial level, city management and the coding of the site. At the same time the research explore the policies and regulations which impact of urban form generating process and clarify the correlation of policies and urban forms. Three classifications were made according to the intervention of urban form: directly affect, indirect impact and no impact. Finally, through cases study this paper demonstrated how urban policy intervention the physical urban form and the process, which has shown that study reveals the impact of policies on the specific physical structure of the form, the results has significance for specification revision of urban policy and urban design.*

Key Words: Urban policy, urban morphology, correlation, intervention

Introduction

Urban form might be described as the result of numerous shaping processes in varying social layers at a given place through time, especially from the power of internal and external economic development and urban policy control the role of economic power to urban form is not transferred by people's motivation, but policy guidance is the main factor that people can directly manipulate the urban construction, moreover urban policy plays very important role particular in China in terms the proprietorship of the land. Therefore, the morphological description is indicative of the different academic disciplines that engage in urban morphology, surely should include the urban policy. In the process of rapid urbanization, China's urban policy have very important impact to the control of urban physical spatial form, at the same time of resolving city functions and safety problems, which also affect the generating progress of urban morphology and bring the urban form issues of blocks integration lower, street interface chaos, urban space organization disordered and urban fabric blurred, such as urban fabric of Nanjing is yet chaos, and not as the clear urban fabric of Manhattan (Figure1, Figure2).

So, in this paper, we have investigated in China urban policy in State level, provincial level, city management and the coding of the site, while through cases study, analyzed the correlation between urban morphology and the policy regulation of land use, building layout, urban space and other aspects. This paper demonstrated how urban policy intervention the physical urban form and the process, which has shown that study reveals the impact of policies on the specific physical structure of the form, the results has significance for specification revision of urban policy and urban design.

Figure 2. Aerial map of Manhattan.

Elements of policy controlling to urban spatial morphology

M.R.G.Conzen considered that the town plan is the complex of three plan elements: streets/street-system, plots/street-blocks, buildings/their block-plans (M.R.G.Conzen, 1960). The majority of morphological studies have focused on the street network pattern, the plot pattern and the building pattern or typology (Kropf, 2011), through controlling to urban land use, streets interface, and buildings layout, the urban policy and regulations can directly or indirectly influence the quality of urban space and shape urban fabric form, which reflects the urban space character of street spatial outline, visual variety, and spatial typologies. For example, in American, the urban development are controlled by using zoning codes and in combination with other laws, local government have divided the land under their jurisdiction to different plots, and determined the nature of each plot and the use of conditional permitted mixed-use, while introducing the idea of urban design, they have determined the controlling indicators of architecture and environment in aspects of physical form of land development, such as ratio floor area, ratio of open space, building density, building height and concession, and using legislation as the legal basis for the control of urban development. zoning codes of American, from its generation to implementation to present, from the protection of private property rights to protect public health and safety, which have achieved great results for controlling urban design and shaping urban morphology, and get promoted in many countries and regions. (Tongji, 2011) Such as, Manhattan's regular street grid and relentless orthogonal plat of hundreds of rectangular blocks and the relationship of street and buildings height, and building

out of plot, which is generated by urban codes (Marshall, 2011). Another, in Hong Kong, urban land exploration has been controlled by planning control combining with regulatory controls, through using district plans of legal and non-legal plans, the local government have divided the land to different use, and mainly controlled to the land exploration intensity by controlling to ratio floor area, plot coverage, buildings height along the street, open space and other aspects, which also get great progress and results. (Tongji, 2011) So, urban codes are important, they can significantly shape the character of our urban areas for better or worse (Ben-Joseph, 2005). According to urban coding and planning practice of New York, French, Kyoto, Edinburgh, and other examples, Stephen Marshall summaries that the content of urban codes mainly focus on regulation of physical components, coded elements and relationships among them. He proposes the purpose of codes has three broad categories: first is utilitarian purpose, concerning issues to do with health and safety, second is to do with the nature of the urban fabric, third is to do with social order ends. (Marshall, 2011) So, we think that policy and regulations mainly control urban physical space from the elements of composition and relationships among them (Figure 3).

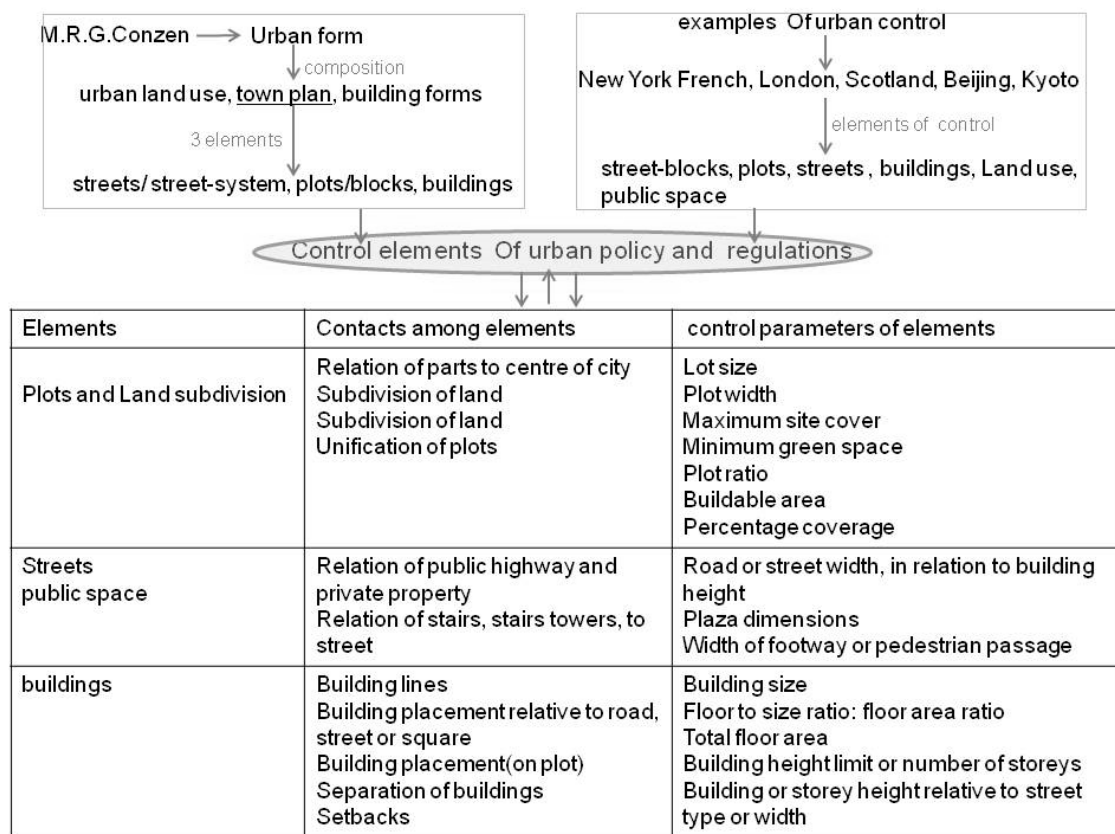

Figure 3. elements of urban policy controlling to urban spatial morphology.

Relevant research status

In relevant research results of urban spatial form controlling, the experts and scholars mainly study the control of urban physical spatial form and city planning from the perspective of history development, geographical context, urban policy and culture heritage. Such as the paper, 'Coding in the French Planning System: From Building Line to Morphological Zoning', mainly studied three core elements of coding in the French planning system---zoning plan, regulations,

mechanism for administering building permits in accordance with the plan and regulations, for exploring the place of coding within the historical development of French planning system and for examining more recent developments of the system that incorporate typhomorphological analysis to make the coding more responsive to local and regional character (Kropf, 2011). Another as the paper, 'How Codes Shaped Development in the United States, and Why They Should Be Changed', it mainly proposed zoning codes, and proposed that in the United States almost all development takes place in accordance with zoning codes, but go far beyond establishing land-use zones to determine how much can be built, where it can be built, and what form development may take--including building height, placement, and total floor area, in the majority of jurisdictions these codes are the most effective planning instruments and the zoning codes define permissible future development for most US communities (Barnett, 2011). Others papers as: 'the Controlling Urban Code of Enlightenment Scotland', 'Machizukuri and Urban Codes in Historical and Contemporary Kyoto', 'Coding as 'Bottom-Up' Planning: Developing a New African Urbanism', and so on. Although these research influence the urban design decision-taking more or less, the current research has not reached an effective level. (McKean, 2011; Baba, 2011)

In China, the relevant academic research has been rarely, only has few research findings. Such as the paper, "Prescribing the Ideal City: Building Codes and Planning Principles in Beijing", interpreted the Chinese building codes in context of design, with a focus on the relationships between architecture and planning within Beijing's history. It casing in traditional courtyard house and imperial buildings, casing in Zhou dynasty city planning, Dadu--Great Capital of Yuan and Forbidden City in the Ming city planning, analyzed the building codes controlling to building size and total floor area of buildings, and controlling to configurations and materials and decorations of building components, analyzed traditional planning principles of streets and city plan pattern. This paper proposed that various studies on Beijing have been published during the past twenty years across a range of disciplines, but what has not been well understood is its planning practice from the perspective of codes(Guo, 2011). More further research finding is the research, 'Nanjing urban morphological study and planning control policy', mainly study the control path and strategy of planning policy to urban form, from the buildings dimension, buildings setback distance, separation of buildings, buildings facade and other ways(Ding, 2007). Other related studies, such as An approach for simulating street spatial patterns(Ding, Tong, 2011) ; Density, height limitation, and plot pattern: quantitative description of the residential plots in Nanjing China (Zhang, Ding, 2012); Urban Plot Characteristics Study: Casing Center District in Nanjing, China (Zhang, Ding, 2012) These research results have get great progress in controlling and shaping urban space form, but which have very few in the controlling effectiveness of urban physical spatial form. So, the body of Chinese codes was large, a systematic study of building codes has not been attempted , and has yet to be fully researched(Guo, 2011). Just under the inspiration of these research results, we are writing this paper.

Investigation of relevant urban policy in China

In China, the specialized urban policy and regulations of controlling urban physical space have no yet, which have some only involved in the related regulations of city planning and administration, from the perspective of rank permissions, the policy related with urban planning and administration mainly include in three levels: laws, regulations, rules and standards, we have completely investigated these urban policy from State level, provincial level, city management and the coding of the site, in these, about the survey of provincial level regulations and local city rules, we have investigated the regulations of Jiangsu province and Nanjing which are related with case analysis of this paper. First, by using the statistical approach, we have collected policy of city planning and administration, according to the intervention of urban

form, we have made three classifications: directly affect, indirect impact and no impact, and statistics the policy regulations of every classification (Table 1, Table 2). Second, with method of mapping (Gauthier, 2006; Ding, 2011), according to the clauses of these relevant regulations directly and indirectly, we have again made two classifications: mandatory clauses and guidance clauses, so which have constituted four quadrants of mapping----directly affect and mandatory, directly affect and guiding, indirect impact and mandatory, indirect impact and guiding (Figure 4).

According to our statistics of policy, as Figure 4 and Figure 5 shown, we conclude that:

First, there are two categories in the policy regulations directly related with urban morphology: the first is Mandatory clauses, which mainly are mandatory provisions of urban land use, buildings position and relevant quantitative indicators, such as building density, floor area ratio, ratio of green land, distance between buildings, distance of buildings back road and river and land boundaries. The second is guiding clauses: which major are guiding regulations of urban space, such as street interface processing, building height, building facades, green, advertising and other aspects. But in these policy regulations, which have been lack in the provisions to plot use nature and exploitation intensity, urban public space, and the area of building back road boundaries.

The indirectly relevant policy provisions of urban morphology, mainly are the regulations about urban planning preparation and approval, each construction certificate approval and issuance, protecting arable land and basic farmland, protecting ecology environment, focusing on sustainable development, remediation city appearance and harmony with urban circumstance. (L-IRNUPO-2007, L-NURPO-2012, P-UGMO-2003, P-URPO-2010, P-OAMM-2010, P-HCTVPO-2010, C-UGO-1992, C-UGPIR-1994, C-IRLAL-1999, C-RWROUP-1999, C-CAMCDPCT-2011) These indirectly relevant urban policy has also related with city image, and also could play a certain macro guiding role to urban land use and building positions, but because of their guiding regulations, and operability no strong, which could not control urban form and resolve urban quality.

Second, the ratio between the policies amount of affecting urban form and total amount of city planning policies is 59.6%. In addition According to our statistics to 99 major policies of affecting urban form, in their policy clauses, the ratio of direct correlation is 18.6%, indirect impact is 30.2%. From the results, we find that in the urban planning policy of national level, provincial level and Nanjing city, actually the policy regulations related with urban land use, building layout and urban space have been more.

Third, in the directly correlation policy clauses, percentage of mandatory clauses is 7.2%, and ratio of guiding clauses is 11.4%. From this, in China's city planning policy, the mandatory regulations of directly affecting urban form are little, such as land use scale, controlling indicators of land exploration intensity, land divisions and indicators of buildings position determining, which mainly been involved in the policy files of province and local city. And most clauses regulation related with urban land use and urban space are guiding, which have mainly been appear in urban policy of three level, especially the national level policy clauses have been basically all guiding regulations, and in these clauses of national level, about the provision of rigid indicators, which all be explained to be carried out by combining with urban planning and management technical regulations.

Correlation between urban morphology and regulations of land use

In the policies directly related with urban form in China, the regulations of land use mainly include in three aspects: the first is mandatory rules of land use scale, land nature, land classification and compatibility of construction land nature, cultivated land transfer non-cultivated land, agricultural land transfer to construction land and plots division, for example, in our policy statistics results of Nanjing city, twenty-two clauses in six rules have these mandatory provisions (L-NUPO-1990, L-IRNUPO-2007, L-NURPO-2012, P-TR-2011), although these regulations have rigid requirement to land use, but have not regulations of quantitative indicators, which all to be pointed out to determine in relevant regulatory detailed planning and relevant planning conditions. Such as, Nanjing urban and rural planning ordinance stipulate: 'Construction land should properly and compatible use land in accordance with the principles of intensively using land. The proper construction scope and compatibility requirements of urban land use should be clearly specified in the controlling detailed planning and determined in planning conditions.' (L-NURPO-2012) Which is very probably to lead to irregular of every construction plot fabric, because each controlling detailed planning has no uniform policy basis of reference. The second is guiding rules of urban land layout, urban function zoning. And the third is controlling indicators regulations of land exploration intensity, such as ratio floor area, buildings density, green ratio and other indicators. In our policy statistics, six clauses in four local rules have these provisions of indicators, such as the regulations of 'Buildings layout must comply with relevant planning and management technical regulations about building density, floor area ratio, distance between buildings, building height, distance of buildings back roads, rivers and railways' (L-NUPO-1990), 'Urban construction should be reasonable control of building capacity. The construction projects of providing public open space for city, could appropriately increase their buildings capacity, and the specific indicators should refer to relevant technical regulations of urban planning.' (L-IRNUPO-2007), 'provisions of up limits and low limits controlling approach of building density, floor area ratio and other indicators in residential land, commercial land, and other types of land' 'controlling

indicators regulations about building base area, building density, floor area ratio and its calculating' (P-CDPG-2012) .

In addition, about the provisions of plots, in China, only the rules of a few local city of more developed economies, such as Jiangsu, Guangzhou, Fujian and other provinces, which have the rules of plots division size and the smallest land unit controlled, but have no provisions about plots exploration intensity, relationship between plots geometric shapes and buildings, land subdivision, and other relevant quantitative indicators. While other local city regulations, such as Ningxia, Gansu, which have not covered related provisions about plots use.

Then, in China, the land exploration intensity through indicators controlling is how to affect the urban physical spatial morphology, so we have selected 99 building cases in old city of Nanjing, and statistics breakthrough of up limits requirements of floor area ratio and buildings density, to analyze its relationship with urban spatial morphology. As Figure 6 shown:

Figure 6. correlation analysis between urban morphology and floor area ratio, buildings density.

Experiment results: 27 indicators of floor area ratio are exceeded, 12 indicators of building density exceeded, and the other comply with policy regulation, which shows that floor area and building density have controlled to the construction amount of land exploration and buildings capacity, and they are effective measures of controlling urban land construction, so also they have certain affect to urban spatial form. In addition, the floor area ratio more higher, the building density is lower, which indicates that the developers comply with the regulation of The implementing rules of Nanjing urban planning: 'the projects of providing public open space for the city, may be appropriate to increase their building capacity', except following the indicators regulation. Thus, although this amount of urban land construction have been controlled, but building height and floor areas could be exceeded, and could affect urban spatial morphology.

Correlation between urban morphology and regulations of buildings layout

The regulations of building layout mainly include in distance of buildings back roads and river, distance of buildings back land boundaries, distance between buildings and. Here, we mainly analyze the impact of buildings retreating road and distance between buildings.

Correlation analysis between urban form and distance between buildings

Now, China's policy regulations related with distance between buildings, which are mainly involved in the regulation of residential buildings spacing. Mainly in the province and local city policy, which have the policy regulations of sunshine spacing factor, sunshine spacing calculation of residential buildings, minimum distance between residential building gables,

minimum distance of layout north and south between residential and non-residential building, and other minimum distance between non-residential buildings. Another, which also have clear regulations about buildings distance of low-rise residential, multi-residential and high-rise residential. (L-IRNUPO-2007,P-TR-2011) These local regulations about sunshine spacing and sunshine standards, directly refer the national rules, "urban residential area planning and design specifications" (GB50180), such as Big Chill date not less than two hours, the winter solstice not less than one hour. Then, the regulation of distance between building is how to affect urban form, so, in old city and east city of Nanjing, we have selected two residential cases, to compare between practical residential plan and planning plan of complying with regulations, as Figure 7 shown.

Experiment results: The residential plan of complying with policy regulation is almost consistent with practical plan fabric morphology, and the residential spatial fabric form appears out neat and clear mechanism features. From this phenomenon, we conclude that these two residential were built with following the policy regulation of distance between buildings, the policy provision have controlled to buildings position in residential, and controlled to urban spatial quality and urban form. However, we have also seen that Ruijin residential of Nanjing, built in 1985, only have ground parking, which would inevitably affect urban spatial land use and spatial quality more or less. And Huayang residential of Nanjing, built in 2000, using underground parking, which has very little interference to urban spatial use and urban form.

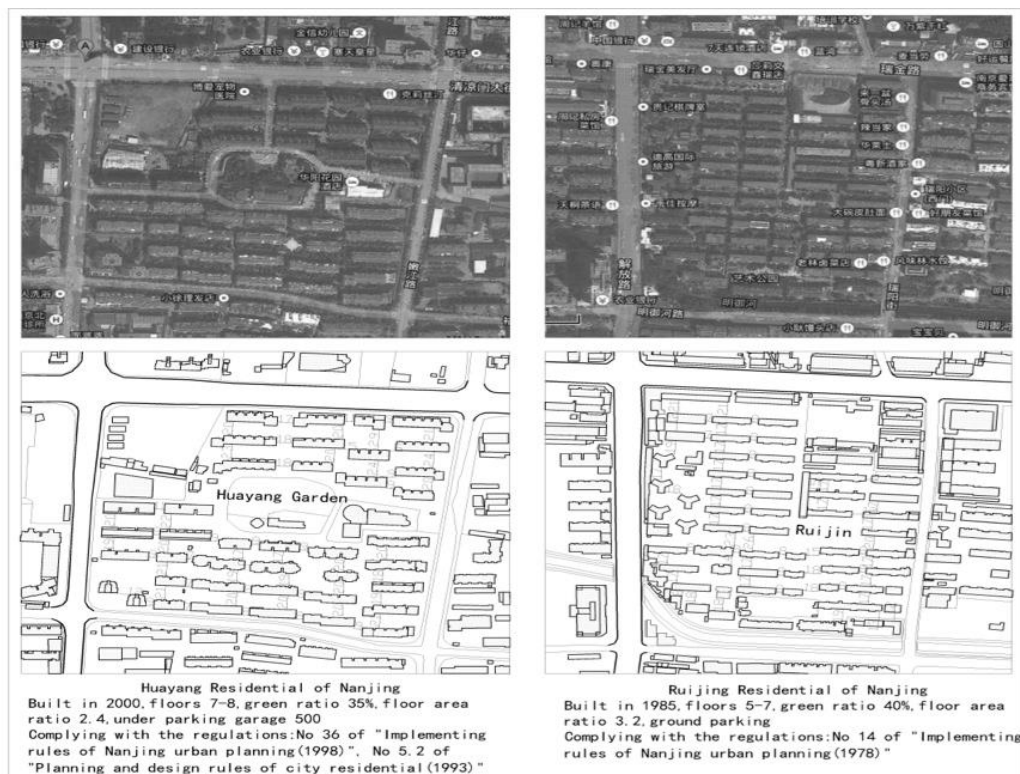

Figure 7. correlation analysis between urban form and regulations of distance among buildings.

Correlation analysis between urban form and buildings back roads

In elements of measuring geometry relationship among the architectural groups, distance is most important, which directly affects the image and scale of groups space. About the provisions of distance of buildings back roads, which are clearly defined in the local

regulations. Case as Nanjing, through investigating urban policy over the past years, we find that the policy of Nanjing's concession streets first appeared in 1928, from 1928 to now, there are three transferring stages: 1928 to 1977--no concession and construction along roads line, 1978 to 1987-- unified concession along roads red line, 1995 to 2007--different concession of different building heights, as shown in Table 3. In these three stages, after analyzing the policy clauses of past several years in Nanjing, we discover that each rules of buildings back roads has all some change, although from beginning they all try to solute road traffic and safety issues at that time, but which affected the cityscape. Because of different regulations of different years, making different generations buildings standing on the same street, so the urban street interface has become very complex, which have caused great impact to urban morphology. Here, we have selected a 946 meters long street from Zhujiang station to Xin jiekou station on Zhongshan Road of Nanjing, to analyze. As Figure 8 shown:

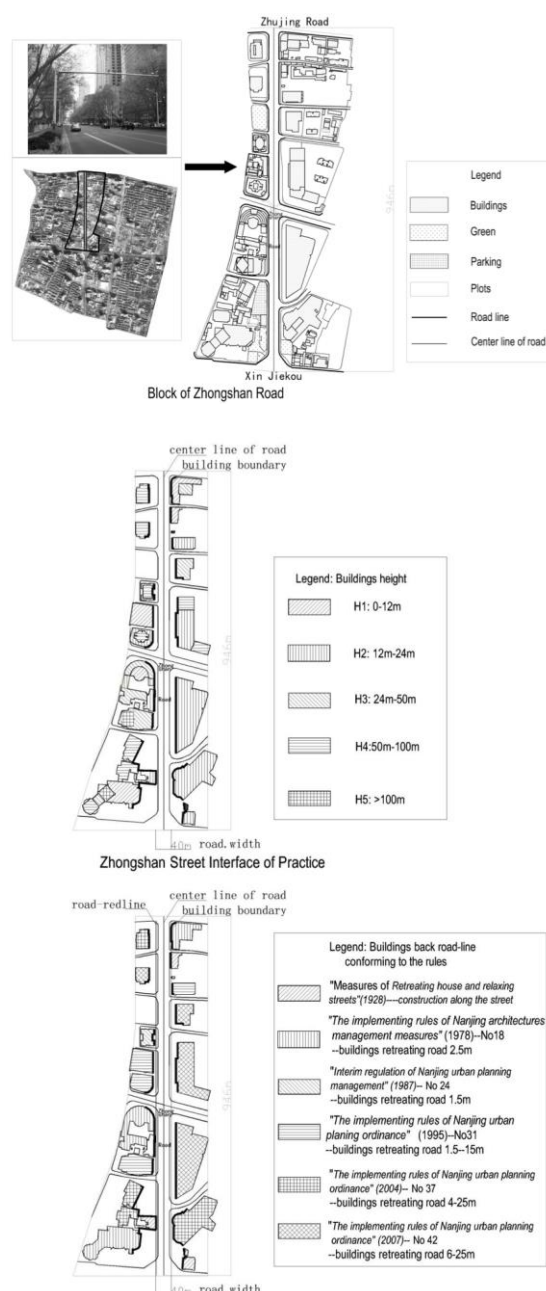

Figure 8. correlation analysis between urban form and distance of buildings back road.

Table 3. From 1928 to now, statistics of policy rules and cases of buildings back roads in Nanjing.

	First stage (1928-1977) construction along roads line	Second stage (1978-1987) Unified concession along roads red line		Third stage (1985-2007) Different concession of different building heights			
Year	1928-1977	1978	1987	1995	1998	2004	2007
Name of Policy rules	Measures of retreating house and relaxing streets of Nanjing city(1928) Buildings rules of Nanjing(1935) Buildings management rules of Nanjing(1948)	Implementi ng rules of Nanjing architectur es manageme nt measures(1 978), No 18	Regulation s of Nanjing urban planning and manageme nt(1987), No 24	Impleme nting rules of Nanjing urban planning ordinanc e(1995), No 31	Impleme nting rules of Nanjing urban planning ordinanc e(1995), No 35	Impleme nting rules of Nanjing urban planning ordinanc e(1995), No 37	Impleme nting rules of Nanjing urban planning ordinanc e(1995), No 42
Concession of comply with rules	No concession	2.5meters	1.5 meters	1.5—15 meters	3—25 meters	4—25 meters	4—25 meters
Cases amount of building Conforming to policy regulation	9	4	6	7	14	17	16
Not Conforming to policy regulation	8	4	5	5	12	13	13
	1	0	1	2	2	4	3
Ratio between cases amount of conforming to policy and total statistics cases amount: 82.2%							

Experiments results:The present status of Zhongshan Street interface is in accordance with the policy regulations of buildings retreating roads. In addition, according to our investigation to 73 cases buildings built differently times (Table 3), 82.2% buildings have been in accordance with the policy regulation of retreating streets. Distance of each different time building retreating roads is satisfied with the policy regulation at that time, the construction more later, the distance of buildings retreating roads id larger, and buildings built before 1978 are construction along the roads. Several buildings built in 2010, such as Kairun Hotel, which retreating the road is more than 15 meters corresponding with policy regulations.

Although the formation of Nanjing Zhongshan street interface is carried out in accordance with policy regulation of buildings concession streets, but from the experiment results, we have seen that the whole Zhongshan street interface shows discontinuous and irregular fabric features 。 So, in China, the relevant policy have controlled the buildings position and affected the urban spatial form, but can't controlled urban streets spatial quality, and its controlling role is ineffective to urban spatial quality.

Third, reasons of causing these status: Changing of different years policies, and the regulation of buildings retreating street belongs to enforced clauses, with higher operational, which made different times buildings standing on a same road, finally forming the status of street interface irregular. In addition, the larger public buildings built after 2007, have retreated the roads more larger distance, on the base of complying with regulations. So, except conforming the regulations of buildings retreating road, they are also complying with other regulation for concession, such as the rules states: 'Urban construction should be reasonable control of building capacity. The construction projects of providing public open space for city,

could appropriately increase their buildings capacity, and the specific indicators should refer to relevant technical regulations of urban planning.' (L-IRNUPO-2007) , while the developers have provided public space in their projects construction, they also have get more floors and improve ratio floor area, and get more economic effect.

Figure 9. Land use in the redline area of buildings back road.

Another, On Zhongshan street, the redline area left by buildings retreating road, also become a problem, the status chaos (Figure 9), in the red zone, because of the difference ownership between sidewalks and concession area, the same street space are often divided into discrete space by paving or other aspects.

In addition, provisions of all kinds of boundaries mainly include in the regulations of roads, rivers, heritage conservation, green, construction control lines and other boundaries. Such as, No 7.1 of "Jiangsu controlling detailed planning guidelines" (2012) , has clear controlling requirements to the position, width, concession distance and protection distance of urban red lines, yellow lines, blue lines, purple lines and green lines. In national policy regulations, such as "Urban green line management measures", "Urban blue line management approach", "Urban yellow line management approach", "Urban purple line management approach", "Historical and cultural relics protection planning requirements ", and other policies, which also have the controlling requirements to boundaries of green, rivers, historical and cultural blocks and land use, but lack of quantitative indicators.

Correlation between urban form and urban space

In urban policy, the regulations about urban space, mainly include in the provisions of urban spatial organization, urban style and local characteristics, public space, street facades and buildings height, building style and color, urban design of city center and important functions plots, outdoor advertising, historical and cultural districts protection, and other aspects. For example, in our policy investigation of Jiangsu province, nineteen clauses in eight ordinances

are guiding regulations of urban space, and in these regulations, which have been lack of relevant indicators of controlling urban space. (C-UGO-1992, C-AL-1995, C-URPL-2008, L-NUPO-1990, L-MONA-1998, L-IRNUPO-2007, L-NURPO-2012, P-UCAESMO-2004, P-OAMM-2010, P-HCTVPO-2010, C-UAESO-1992). Then, these guiding regulations how to affect urban physical spatial form, from the aspects of street facades and buildings height, building facades and advertisement, we mainly analyze their influence to urban form.

First, the analysis of street facades and buildings height, in relevant local policy, which have the regulations of buildings concession roads according to street width and building height along streets. Such as the prescribe 'The buildings on both sides of the road which width is more than 30 meters or less than 30 meters, must retreat road redline corresponding distance according to buildings height over 24 meters or less than 24 meters (L-IRNUPO-2007). In accordance with this clause regulation, we have drawn out experimental model of street spatial interface, finally find, the road more wider and the building more higher, the distance of building back roads is more larger. So, various types of buildings on both sides of urban roads, because of their different heights, they retreat roads inconsistent distance, which makes urban street spatial interface becoming no uniform (Figure 10, Figure11).

Second, the impact analysis of building facades regulations: No 54 of "Implementing rules of Nanjing urban planning ordinance" states that 'Strictly controlling to the residential construction on both sides of the major road, and where construction should handle street facades well, shall not impede the urban landscape.' (L-IRNUPO-2007) Another, No 57 states that 'Prohibited to set unidirectional retreat floors in north of multi-storey residential and high-rise residential, in order to meet the building spacing concession requirements.' From these two clauses regulations, the provision purpose of No 54 is to improve building facades along the street, but existing two issues: first, lack of the definition limitation of "the major road", limiting the definition whether according to road width, or traffic flow. Second, "handle street facades well" is a relatively vague concept, no operability. According to "Nanjing controlling detailed planning", in the old city of Nanjing, planning public construction land 1195 hectares, which included in commercial land 447 hectares and road land 759 hectares (Ding, 2007). If complying with this provision, both sides of roads are all used for commercial development, the construction is far more than current required, so No 54 is difficult to be implemented. To control the street facades better, it may need more operational policy. Moreover, the regulation 'Prohibited to set unidirectional retreat floors in north' of No 57, is almost impossible, because of sunshine under the premise of the old city land increasingly tense (Figure 12).

Figure 10. Zhongshan street spatial interface from Zhujiang station to Xin jiekou station.

Third, the influence analysis of advertisement setting: In relevant urban policy, the regulations about advertisement setting mainly are guiding clauses, and no enforced regulation, also no controlling indicators. For example, No 58 of "The implementing rules of Nanjing urban planning ordinance" (2007) states that 'Outdoor advertisement setting and signs facility should be suitably located, proportion coordination, style and scale harmony with the surrounding environment', we know this clause has no operational quantitative indicators.

Figure 11. buildings of different height back roads.

Ashihara Yoshinobu proposed that advertisement of side street is the main problem affecting the facade. When sidewalk is less than 3 meters, building facades are obscured by advertising; when sidewalk greater than 11.5 meters, street is a haven for walkers. According to Nanjing city policy of buildings back roads, the minimum distance of buildings retreating road red line is 6 meters, plus the sidewalk, a distance of 11 meters is not difficult, but advertising of Nanjing is still chaos, also affected the street interface morphology. Then, whether advertising could be controlled? We think that urban policy can control advertising sizes, but advertising content is difficult to control (Figure 12), this may be the main reason of advertising not to be resolved on urban streets. In addition, if unifying advertising form and style, and harmony with surrounding environment, which will lose the effect of advertisement catching people's eye. If advertising isn't able to attract people's attention, it also can be counted as a real advertisement?

Figure 12. Retreating floors of building; advertisement along street

Conclusion and Discussion

In this paper, through investigation of urban policy directly or indirectly related with urban physical spatial form, we find that China's relevant policies related with urban spatial form

actually have been more: which mainly include in mandatory regulations of urban land use and building layout, and guiding provisions of urban space. And through the correlation analysis, we concluded that the mandatory regulations have played the controlling role to land development intensity and buildings location, and have the important impact role to urban physical space shaping, but which have not controlled to quality of urban spatial form. Among them, the regulation of playing important role is quantitative indicators, such as building density, floor area ratio, distance between buildings, distance of buildings concession and other indicators. The mandatory provisions have controlled the land exploration intensity and building location, and affect urban space organization, but not control and resolve the quality of urban physical spatial form. So, China's city yet remains the urban form problems of blocks integration lower, street interface chaos, urban space organization disordered and urban fabric form blurred. Through experiments, we think that the main reasons of making these urban form problems mainly have:

First, the indicators regulation, such as building density, floor area ratio, green ratio, distance between buildings, distance of buildings concession and other indicators, is mandatory clauses provision, with a very high operational and implementation efforts. From top to bottom, which could be get consistently implementation, but it is this implementation and policy changes over the past years, different periods buildings retreat street inconsistent distances, these buildings stand on the same street, finally making the street interface chaos and greatly affecting the urban spatial morphology. So, in the improvement of urban landscape and safety and urban functions, adding more elements of urban form controlling may be important,

Second, the policy regulation about urban space of street interface relationship handling, advertising and other aspects, is the most important urban spatial form requirement, however, these regulations only are guiding requirement, no mandatory and no operability, which have not play the controlling role to urban spatial morphology. So, we consider that in these guiding rules, adding quantitative indicators may be help to control urban physical spatial morphology better.

Third, in the relevant urban policy, lack of the follow regulations: No controlling provision about area and angle after buildings retreating road red line; No special and required drawings in programs approval and experts evaluating, which weakening the seriousness of planning approval and experts assessment; Lack of the regulation of architectural surroundings and plots subdivision, which making architect didn't have a high reference as guiding in the design process, so that each single building only based on their own form and developing interest, finally causing urban spatial form chaos.

So, it is completely impossible that only relying on urban policies to control urban physical spatial, it could also need to consider other factors, this may be the our research work in subsequent studies.

A subtropical urban taxonomy: the tension of research informing practice

Peter Richards

QUT - Queensland University of Technology.

E-mail: p.richards@qut.edu.au

Abstract. *Urban Morphology provides an important framework of analysis for understanding growth and change in cities. For the urban design and architecture practitioner however, urban morphology research only provides part of an approach. The task is often to plan for, or design much larger, taller and coarser grained buildings. The demands in new projects with planning efficiencies for lifts, larger floor plates for working and retail make footprints much larger. Accommodating car parking and service vehicles, often above ground, adds complexity to the lower levels of buildings, urban interfaces and public realm. The urban challenge is to fit these projects into existing, usually finer grained blocks, places and buildings. These factors combine to make traditional building types inappropriate for new projects and the sole repetition of traditional urban patterns is not possible. These issues are of a particular challenge for Brisbane, which is a city in search of a subtropical urbanism as a new world city, two aspirations of government visioning for the city. But new buildings can contribute to the city and have good urban manners. Using Brisbane as a case study, this paper proposes a method of creating an urban taxonomy of new urban building and places types that respect the existing city. This work reflects upon recent practice and also draws inspiration from the Form Based Codes movement in the USA, which has a strong emphasis on the essential building types needed to create good urban places. The taxonomy is ongoing research that would benefit from the scrutiny of urban morphology researchers.*

Key Words: Subtropical, taxonomy, new urban building types.

Introduction

Urban Morphology provides an important framework of analysis for understanding growth and change in cities. For the urban design and architecture practitioner however, urban morphology research only provides part of an approach. The task is often to plan for, or design much larger, taller and coarser grained buildings. The demands in new projects with planning efficiencies for lifts, larger floor plates for working and retail make footprints much larger. Accommodating car parking and service vehicles, often above ground, adds complexity to the lower levels of buildings, urban interfaces and public realm. The urban challenge is to fit these projects into existing, usually finer grained blocks, places and buildings. These factors combine to make traditional building types inappropriate for new projects and the sole repetition of traditional urban patterns is not possible. These issues are of a particular challenge for Brisbane, which is a city in search of a subtropical urbanism as a new world city, two aspirations of government visioning for the city.

But new buildings can contribute to the city and have good urban manners. Using the desired Brisbane as a case study, this paper proposes a method of creating an urban taxonomy of new urban building and places types that are a response to the regulatory and policy environment, some market preferences while respecting the existing city. This work draws upon recent research and practice, and the form-based codes movement in the USA, which has a strong emphasis on the essential building types needed to create good urban places.

There is an essential tension in the way that urban morphology research can inform practice. Urban morphology forensically examines urban patterns of blocks, streets and building types that have occurred throughout history and charts a rich and nuanced retrospective of how a

place has come to be. For the practitioner with an interest in urban morphology, this research is fascinating, but it does not necessarily inform what to do next.

Mostly, the task of what to do next is to design different, larger and taller building types that respond to current community and client expectations. These expectations are codified in the higher densities encouraged in town planning schemes and are defined by the construction systems, buildability and design requirements of the construction industry controlled by the Building Code of Australia. In addition, market and client preferences have a major influence of design choices. The practitioner's observation is that this approach may have always been the situation. A pragmatic opportunism influences what we do next. When historical buildings were built as new, they were, most likely, not informed by detailed urban morphology research (partly as the study emerged after the second world war) but by the needs of the day and the conventions of design and construction.

A desire for these larger and taller buildings, the advent of new materials and construction systems like steel and concrete and of course lifts have transformed historic city patterns and continue to do so. However, these buildings did not necessarily destroy the urban fabric, but added another layer to the urban pattern. These buildings still had an urban character and form and contributed well to the urban environment, by doing simple things such as aligning building fronts to streets and filling available frontages. Entries were visible and accessible from streets and in more built up areas a variety of ground floor uses with individual entrances in shop fronts activated streets. Facades had depth and detail, windows and walls were often vertically proportioned and horizontal mouldings broke up the vertical scale. A strong human scale was evident. These attributes are the obvious urban conditions and for a practitioner committed to urbanism, can be readily applied to buildings designed for current needs.

The framework

This paper proposes a framework for an urban taxonomy. Taxonomies are not focused upon uniqueness, but how elements with common characteristics comprise and combine to form identifiable urban patterns. At its core is a range of residential, commercial and mixed-use building types of varying densities that emerge from the current regulatory environment and market preferences. In essence, the types will be a response to the pragmatics of everyday architectural and urban design practice. The essential requirements of the Building Code of Australia, Queensland Planning Policies and town planning schemes that shape design responses are determined. Market preferences that influence the form of development include recognised industry preferences and examples of good practice often as response to the regulatory framework.

Urban blocks are seen as a fundamental ingredient of urbanism. The resultant building types of varying scales and intensities aggregate to form the urban block types. These blocks help define the resultant street patterns and are grouped to make settlement forms of various densities and land-use mixes. These types address the specific issues and opportunities of Brisbane City on the eastern seaboard of Australia, a city of 1million people in a region of 3 million growing to 4 million over the next 25 years. With its latitude of 27.5 ° south of the equator, the resultant urbanism is subtropical reflecting the climate of this region. This work will suggest a taxonomy for a contemporary subtropical urbanism, one that can integrate with traditional urban patterns.

The taxonomy should also include other attributes that make up the urban fabric, such as street types, open spaces, types of plazas, parks and gardens as well as arcades and courtyards within developments. This part of the taxonomy remains underdeveloped. The framework of the taxonomy is described in figure 1.

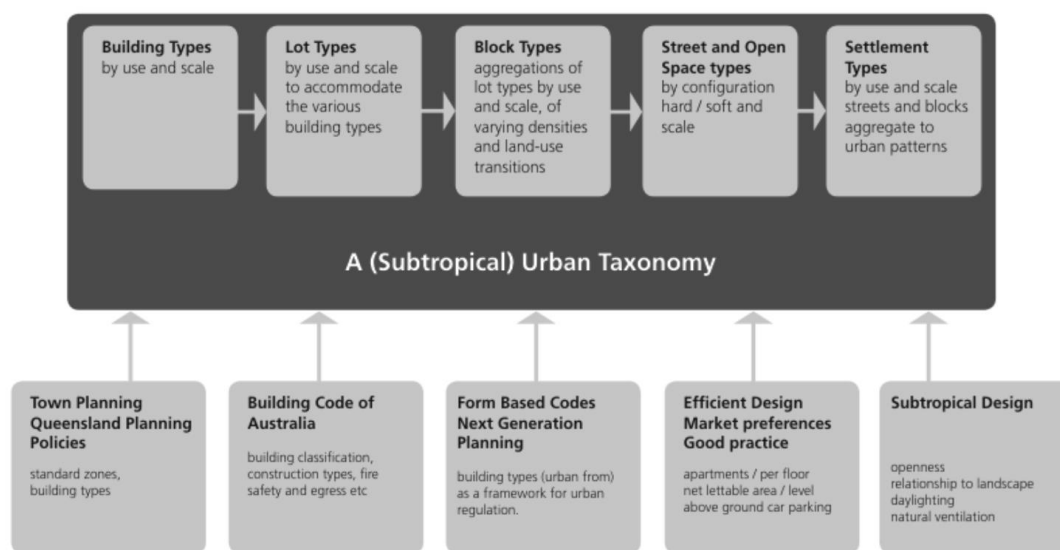

Figure 1. Taxonomy framework.

Town planning: Queensland planning policies

Town Planning regulates land-uses and determines design controls for the resultant preferred development forms for specific locations. In Queensland, town planning schemes are shaped by the Queensland Planning Policy (QPP) framework, which recommends a series of standard zones. (DSDIP, 2013) To achieve consistency throughout the state, the zones have specific colours for each, to be used in planning schemes. The QPP classifies types by both land use and density. Two groups of zones, the residential types and the centres types, strongly influence the resultant urban form.

The residential zones are; rural, low, low medium, medium and high and can include character housing as separate zone. They are coloured in a range of pinks to darker reds. The range of high density is 8-15 storeys, medium density, up to 5, low medium, 2-3, low density and character residential is 1 to 2. The centres zones, from the highest to the lowest, are; principal, major, district, local and neighbourhood. Other primary zones include and industrial uses and community uses that range across all densities. The land-uses with their preferred colours have been arranged in a table with a cross section of built form demonstrating their approximate density. (Figure 2)

Residential Uses

Low density residential provides for predominantly dwelling houses on a range of lot sizes. This development form reflects and enhances the existing low-density scale and character of the area with a maximum building height of 1-2 storeys. Some small-scale non-residential uses that provide local work places and complement local residential amenity can be included.

Low-medium density residential is 2-3 storeys and has a broader mix of dwelling types including dwellings, row houses, small secondary houses and duplexes, villas and small scale multiple dwellings. This development form can include apartments, residential care facility or retirement facility and can be supported by community uses and small-scale services and facilities that cater for local residents. This density facilitates urban consolidation in predominantly residential areas with multiple dwellings and short-term accommodation for visitors encouraged clustered around or near centres and transport nodes. Development provides a high level of amenity and is reflective of the surrounding character of the area.

Medium density development provides for multiple dwellings up to 5 storeys and can include aged care or retirement facilities, hostels, hospitals and short-term accommodation. These uses are clustered around or near centres and transport nodes thus facilitating urban consolidation. A diverse range of community facilities, transport options, employment nodes and commercial and retail hubs support this zone. High density residential provides for higher density multiple dwellings with similar types with medium density, but 8-15 storeys in height. Development provides for high density multiple dwellings in locations clustered around or near centres and transport nodes. Local plans may specify the ultimately heights.

Character residential is sensitive infill of a similar scale and character as well as preserving existing dwellings. The QPP residential Zones are shown in cross section in figure 3.

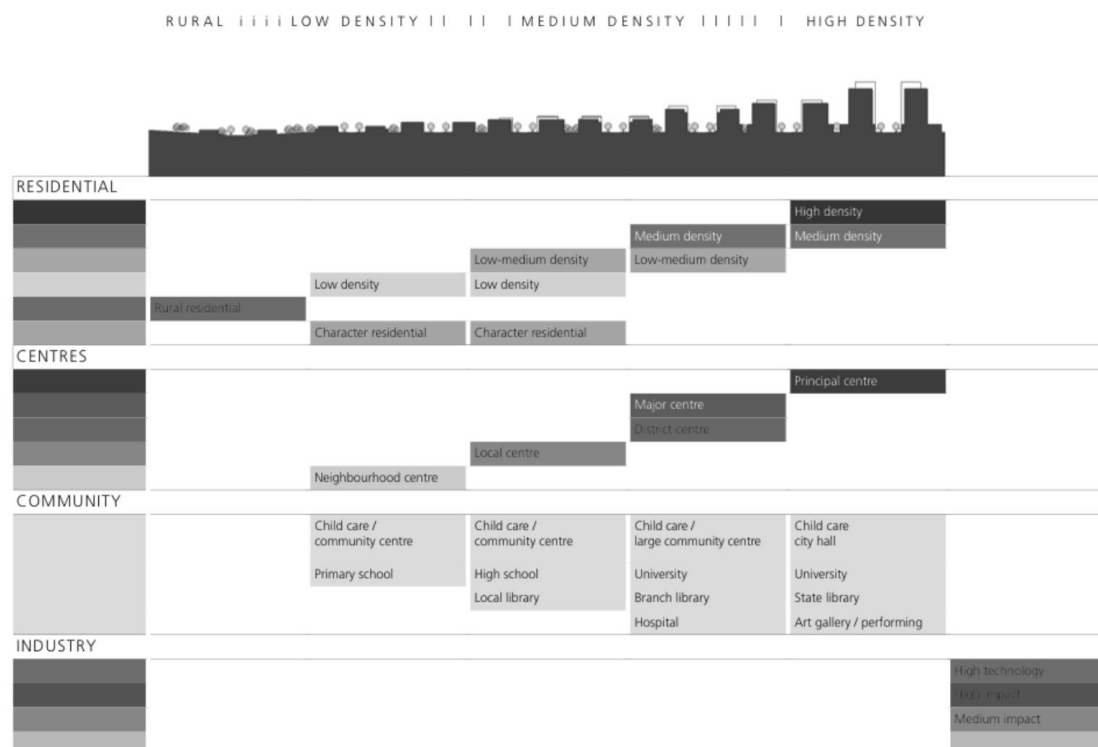

Figure 2. QPP standard zones by type and density.

LEVEL	High density	Medium density	Low-medium density	Low density residential	Character residential
Description	Higher density multiple dwellings supported by community uses and small-scale services and facilities that cater for local residents.	Medium density multiple dwellings supported by community uses and small-scale services and facilities that cater for local residents, in locations clustered around or near centres and transport nodes.	Mix of dwelling types including dwelling houses and multiple dwellings supported by community uses and small-scale services and facilities that cater for local residents.	Predominantly dwelling houses supported by community uses and small-scale services and facilities that cater for local residents.	A predominantly residential area with a particular character supported by community uses and small-scale services and facilities that cater for local residents.
	8 to 15 storeys	3 to 5 storeys	3 storeys	1 to 2 storeys	1 to 2 storeys

Figure 3. Queensland Planning Policy Residential zone definitions by type.

Centres zones are mixed-use, usually with retail or commercial ground floor uses with residential or offices above. Centres are classified as five types, based upon density and uses including varying increments and sizes of retail. They are coloured as a range of blues. From the largest to the smallest these are Principal, Major, District, Local and Neighbourhood.

The Principal centre is the central business district or city centre and has the widest range and highest order of retail, commercial, administrative, community, cultural and entertainment activities. Residential development, short-term accommodation and tourist accommodation is provided at an appropriate scale and integrates with and enhances the fabric of the centre. Service industry uses may be located in the zone. Public open space areas such as malls, plazas, parks and gardens are provided.

Major centres are the next order centres with a mix of uses and activities. It includes concentrations of higher order retail, commercial, offices, residential, administrative and health services, community, cultural and entertainment facilities and other uses capable of servicing a sub-region in the planning scheme area. A broad range of higher order retail, commercial, administrative, community, cultural and entertainment activities is provided. Residential development, short-term accommodation and tourist accommodation is provided at an appropriate scale and integrates with and enhances the fabric of the centre. Service industries may be located in the zone. Public open space areas such as malls, plazas, parks and gardens are provided. Maximum building heights are usually specified by the more detailed neighbourhood plans, but 5 to 8 storeys are typical.

District Centres include a concentration of land uses including retail, commercial, residential, offices, administrative and health services, community, small-scale entertainment and recreational facilities capable of servicing a district. Local centres are smaller again, with limited range of retail, commercial and community activities to service local needs. Neighbourhood Centres are the smallest and contain the least mix of land uses to service residential neighbourhoods. It includes small-scale convenience shopping, professional offices, community services and other uses that directly support the immediate community with development up to 3 storeys. Figure 4 represents the scales of the various centres zones in cross section.

Figure 4. Queensland Planning Policy Centre zone definitions by type.

Building Code of Australia

Like all building codes, the Building Code of Australia (BCA) regulates fire resistance, construction methods, access and egress, health and amenity, which includes day lighting, and

more recently energy efficiency. Requirements change based on use, height, and in some cases floor area. (Australian Building Codes Board, 2014) The BCA utilizes a form of taxonomy and classifies buildings into 10 types. Classes one to four are residential with lower densities the lower numbers. Class five is office and six is retail. Class seven buildings are warehouses and car parks with laboratories and factories class 8. Public buildings are class nine and non-habitable outbuildings are class ten. There are additional requirements for mixed class buildings where the different classifications are located together, either side by side or above. Fire safety, access and egress are a primary determinant of building form and are influenced by the type and height of the building. A key issue is the number, one or more, and types, of escape stairs and whether these stairs are fire enclosed or open.

Offices, Class 5, do not need a lift when up to 3 storeys and the upper floors are less than 200 square metres per level. This is a small footprint a little larger than a house. These buildings do not need to fire enclosed fire stairs either enabling a single open stair. Above 3 storeys and upper floors greater than 200 square metres, lifts are required. At this height, fire stairs need to be fire enclosed, making it a service space and not appropriate for the primary public access in the building. If there is a lift and single stair in an office, each part of a floor needs to be no more than 20 metres from the stair, which limits the floor plate to about 1000 square metres. Larger floor plates usually require 2 or more stairs, which need to be a minimum of 9 metres and a maximum of 60 metre separation. These dimensions will enable larger floor plates of up to 2000 square metres or more.

Residential Buildings

In residential buildings up to 3 storeys with at least one residence on the floor of access, lifts are not required and the fire escape stairs can be open. Above 3 storeys, fire escape stairs need to be fire enclosed, so lifts are usually provided, while not specifically required under the building code. Residential buildings higher than 3 storeys, but below 25 metres to the uppermost floor level, (8 to 9 floors high) can have a single fire enclosed escape stair that is not pressurised. In this case, entrances to each apartment must be 6 metres from the stair entry, limiting the number of apartments per floor to around 5 or 6 or 500 square metres or so. Above 25 metres to the uppermost floor level, two fire stairs are needed and they need to be pressurised and the overall building sprinkled. This significantly adds to cost in Australia.

Like in Class 5 offices, the two fire stairs need to have a minimum of 9 meters separation but a maximum 45 metre between stairs. Entries to apartments are 6 metres from a choice of two directions to the fire stairs. (BCA Part D1.4). The 45 meter separation suggests a maximum footprint of closer to 1,000 to 1,200 square metres. If there is a 3 meter setback for walls along side boundaries, additional fire safety is not needed. At this distance, windows can be incorporated, but it is the town plan that normally determines these setbacks. The Building Code determines the nature of the fire safety and the resultant construction systems. Where balcony access is incorporated in apartment buildings, apartments can obtain light and ventilation from the balcony if there is a 1.5m sill or fire protection to windows.

Cost effective design, market preferences and good practice

The building code requirements can influence design outcomes with certain thresholds for design efficiencies and therefore cost which shape the form of buildings in Queensland. There is a desire to maximize the number of apartments per level while minimising the number of stair and lifts. Apartment buildings below 9 storeys can have a single fire stair and lift with around 5 or 6 apartments per level. Privacy is a strong consideration in higher density design. Different apartments facing each other should have a separation between 18 metres and 24 metres to enable privacy in higher densities. This dimension is the scale of a street, but can be applied

across rear and side boundaries. Building forms should be shaped and site sizes chosen to enable these privacy issues to be addressed while still addressing streets and public spaces.

The apartment configuration is recommended as balcony access with small internal courtyards. This enables cross ventilation and locating a habitable room adjacent to the balcony. This can make apartments two rooms wide, not three rooms, making more efficient plans. Larger apartments are usually located on the ends of buildings where there are two external walls for rooms. Side setbacks of 3 meters enables natural ventilation without fire protection.

In office buildings, there is a commercial imperative for larger floor plates of 2,000 square metres, especially for 'A' grade office space (Destravis, 2013). This potentially can create very deep plans. Day lighting is an important design requirement for all buildings to create better quality internal spaces and better energy efficiency. Good practice office design recommends that 16 metres building depth wall to wall with 12 metres. A desired floor plate efficiency of core to net rentable area is around 85%. (Destravis, 2013)

Car parking is a major contributor to development costs. Higher densities are now more easily achievable as there is a trend for lower car parking rates in urban areas where good public transport is available and cycling and walking is encouraged. Basements are expensive to construct and there is pressure to locate car parking above ground. The above ground requirement presents a number of challenges. Dwellings can be separated from the street thus reducing casual surveillance, unless the parking is sleeved by street fronting apartments. In order to naturally ventilate and light car parking, the three metre setbacks would apply. These responses make sites larger with a depth closer to 35 metres.

Form Based Codes

The form based codes movement in the USA has made a significant contribution to the regulation of future urban form. (Parolek, 2013) A form based code frames urban regulation with a morphological approach utilising building types as the primary structuring element of the code, not land-uses which are the primary focus of town planning schemes. A prominent feature of the form-based code is identifying the range of building types proposed in the place. These types are shown in the code in a line from the least dense to the densest. (City of Santa Ana, 2010). This taxonomy has become a characteristic of the form based codes approach.

Next Generation Planning

The Next Generation Planning (CoMSEQ, 2011) by the South East Queensland Council of Mayors is a policy guideline based on extensive research of local settlement patterns and forms. It utilised in part an urban morphology approach. CoMSEQ is the peak body of all local councils in South East Queensland and the project was conducted with a number of them. Examples of good urbanism identified by the local councils, were measured and recorded with drawings and photographs. Conclusions were made about preferred building types, streets lot sizes and settlement forms that had created these desirable urban places. Underpinning the work was an objective to better define smart growth for South East Queensland.

The NGP proposed a series of urban place types, conceived as neighbourhoods scaled upon a five-minute walkable catchments of 400m diameter. The neighbourhoods had centres, which generally accord with the centres types described in the QPP. The place model was drawn as a cross section from the lowest to the highest intensity. This graphic was inspired by the new urbanist transect developed by the United States urban design firm Duany Plater-Zyberk. (Duany, 2009) The places were: P1, Rural places; P2, Rural townships; P3, Next generation suburban neighbourhoods; P4, Urban neighbourhoods; P5, Centres of activity and P6; Central Business Districts. (Figure 6) The contribution made by the NGP was the idea that each of the centres should be conceived as a neighbourhood, so would have relatively specific arrangements of zones around them within the neighbourhood catchment. Major centres would have higher

density housing nearer the centre with medium towards the edges. Local centres would have low to medium density close by but be predominantly low density. Ranges of community uses of varying scales were distributed in these centres. The land uses were taken from the standard zones from the QPP. The NPG also developed indicative plans for two of these neighbourhood types (Figure 7) (CoMSEQ, 2011).

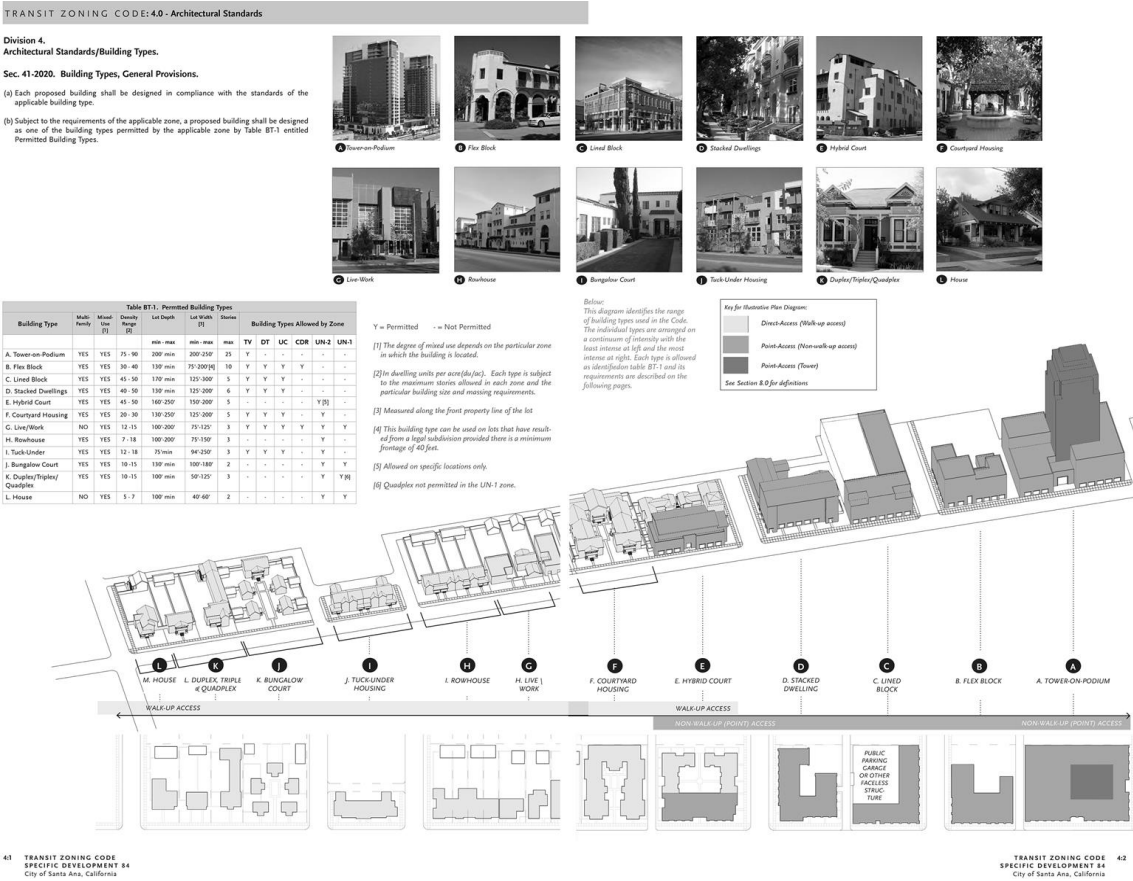

Figure 5. Building types Santa Ana Transit Renaissance Form Based Code.

Figure 6 SEQ Place Model.

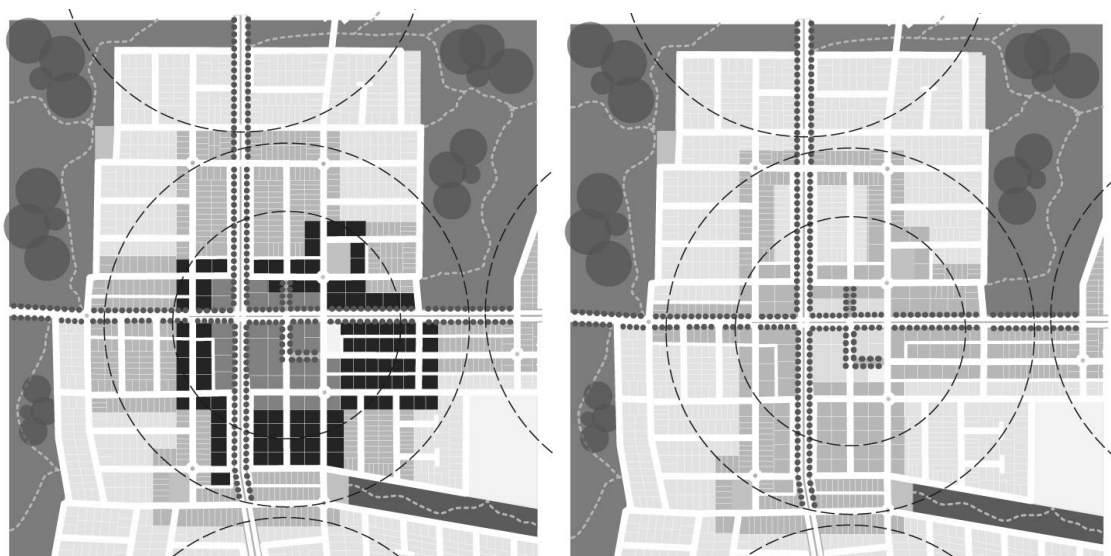

Figure 7. SEQ place types, urban neighbourhoods, next generation suburban neighbourhoods.

Subtropical Design

The philosophy that design can primarily respond to the qualities of place, climate and culture is strong in South East Queensland. A Centre for Subtropical Design was established by the Queensland University of Technology (QUT) and the Brisbane City Council in 2003. The centre has undertaken research into many aspects of subtropical design principles, building types and development forms. Openness and relationship to landscape are two key subtropical design qualities advocated by the centre. Other principles include respect for good orientation, topography, the integration of landscape, opportunities for outdoor living with a strong connection of inside to the outside. Edges between inside and outside are blurred with transition spaces that incorporate verandahs, terraces and courts. Inside spaces can have the character of outdoor spaces and outdoor spaces have the character and enclosure of inside spaces. (Kennedy, 2011)

Subtropical design principles focus on building forms that enable cross ventilation with a priority for narrower buildings and appropriate orientation with the longer sides facing north. Many of these qualities could be interpreted as non-urban and this is one of the challenges in achieving more subtropical design responses in an urban context. In order to enable ventilation within and around dwellings and day lighting, there is a preference for free standing buildings and balcony access apartments.

Detached building aggregating to form an urbanism is a characteristic of subtropical Brisbane. While the city centre has many attached buildings, outside of the city centre much of the city fabric comprises groupings of detached buildings with narrow side and frontage setbacks with larger rear gardens. This includes commercial and retail buildings along main streets. Their primary outlook is front and back irrespective of orientation. These buildings still form streetscapes with urban character, but enable vegetated front gardens and glimpsed views between buildings to green vegetated areas behind. Paddington remains a good exemplar of these patterns, with the main street curving with the ridgeline topography and the grid of residential streets in a relatively orthogonal grid in the valleys. (Figure 5) This characteristic has informed the development of the building types for the taxonomy.

Figure 8. Aerial, overview and detailed view of Paddington, Brisbane, Nearmap, 2014.

The Taxonomy

The taxonomy is framed as series of elements from the more specific scale of buildings to lots, blocks, streets and open spaces to the way these elements combine to form settlement types defined by a 400 metre five minute walk, a neighbourhood scaled urbanism. The settlement types also include the suite of public buildings that provide community focal places and the collective life of the community, but these are not yet described.

The range of building types are not dissimilar to the form based codes array of building types and are described in a series of tables. (Figures 9,10,) There are two types completed, offices and residential/mixed-use. They are arranged from the smallest to the largest, the least dense to the highest density. Plans at the same relative scale are shown. Both tables suggest resultant site sizes to accommodate these buildings. Yellow is used as the colour for useable space, beige for walkways and balconies, darker orange for lifts and stairs and paler orange for service areas, plant rooms etc. Each higher density is coloured as a darker grey tone.

Figure 9. Office building types taxonomy.

Figure 10. Residential building types taxonomy.

These various building types and densities can be arranged for living, working and mixed-use. Three neighbourhood types are proposed and these are taken from the middle range of the Next Generation Planning document. (CoMSEQ, 2011) The place types are P4, P5 and P6 and for this taxonomy, P4, the Next Generation Suburban Neighbourhood, is just called Suburban. P4, Suburban neighbourhoods, comprise predominately individual dwellings with a small amount of attached housing around a small centre with locally focused community facilities. P5, Urban neighbourhoods, are higher density, walkable, mixed-use neighbourhoods. Their centres are strong community focal places and include mixes of retail, employment and community uses. Housing is generally attached. Urban neighbourhoods can incorporate universities and hospitals. P6, Activity centres, are the primary urban focal places in settlements. Densities and land use mix are high. Significant employment is provided and regional scaled civic, cultural and community uses are included.

Natural and rural areas, the rural townships and the CBD are not included as these do not form significant parts of newer urban areas, where activity centres are the highest order centre. Each neighbourhood type is drawn in cross section with the relative heights of buildings shown. The higher the density, the darker the grey colour. A table has been prepared summarising the residential, centres types, which are commercial and residential mixed use buildings from the lowest to the highest density. The neighbourhood types are located above the development intensities. Suburban neighbourhoods are at the lower end. Activity Centres are at the higher end and urban neighbourhoods are in between.

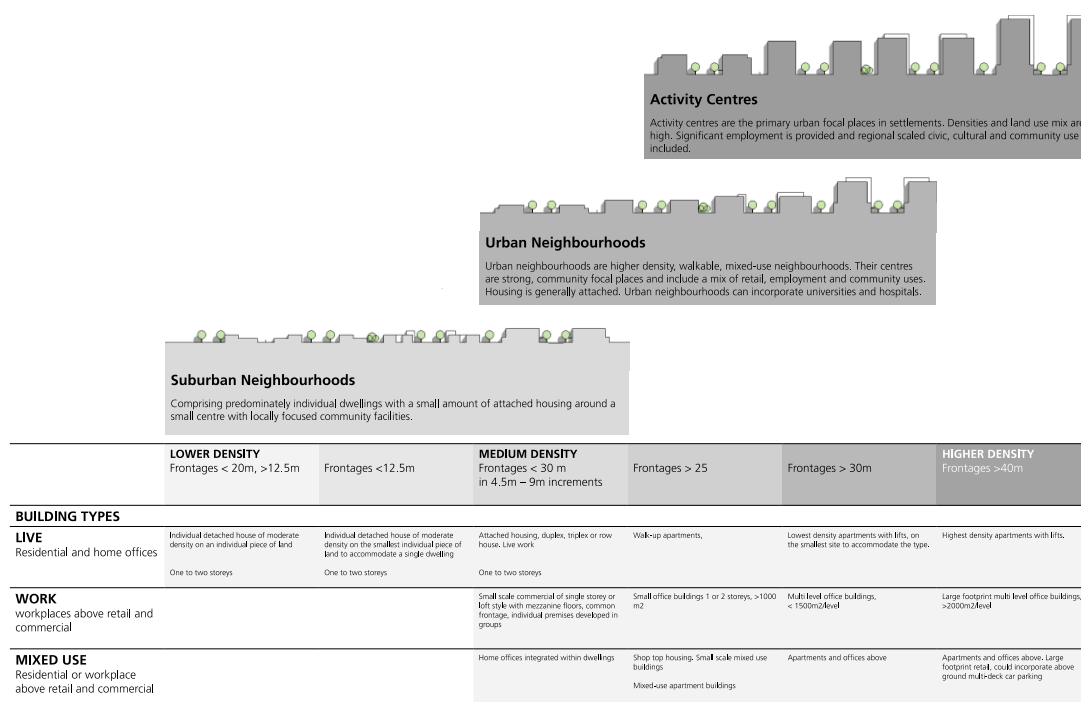

Figure 11. Settlement types form and density, suburban neighbourhoods, urban neighbourhoods, activity centre.

Utilising the approach of the form based codes array of building types, the building types from figures 9 and 10 are arranged as a series of seven generic urban blocks in the form of a figure / ground drawing. The blocks are arranged from the highest density to lowest density and show the transition of building types across the blocks along block edges. The same types face each other across streets, so the transitions are made at the rear of blocks. The highest density blocks have the largest buildings, big footplate offices and high density housing. The lowest comprise predominantly detached housing. Street trees are included as this is a strong

characteristic of subtropical urbanism. The block sizes are all around 150 metres long and between 60 to 75 or 80 metres wide for the larger commercial blocks. (Figure 12)

Figure 12. Settlement types, suburban neighbourhoods, urban neighbourhoods, activity centre.

The settlement or place types then comprise arrangements of these urban blocks within the walkable catchment. The generic blocks have been adapted to respond to each of the neighbourhoods utilising the approach for streets and land-use transitions in the generic blocks. Plazas and parks are also included in these figure ground diagrams to elevate their importance in a subtropical urban context. This suggests an enrichment of the Nolli figure ground drawing including both built form and a coloured landscape.

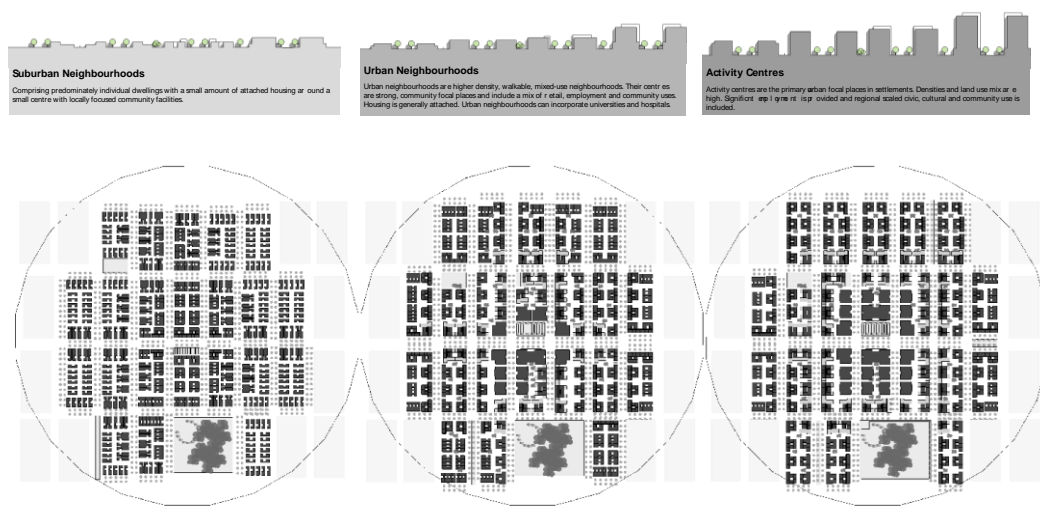

Figure 13. Settlement types, suburban neighbourhoods, urban neighbourhoods, activity centre.

Conclusions

This paper has attempted to represent for the first time a broad range of urban thinking yet remains an incomplete and ongoing piece of work as a taxonomy of urbanism. The research process has combined the local policy and regulatory framework of practice with observations of the Brisbane urban context. This resultant urbanism can represent a settlement form particular to this subtropical place, hence a (subtropical) urban taxonomy.

Some gaps still remain. Street and open space types characteristic of subtropical places have not been identified and described. The building types identified presently do not entirely correspond with the types in the blocks. The regular block structure and street grid does not take into account site features drainage lines, topography or views so would need to be adapted as required.

Despite these issues, the ambition of the research was to combine the elements incorporated as a way to describe urban places. The aim is to continue to locate and make relevant the philosophies of urban morphology within contemporary architectural and design practice.

Shaping the city. Public space in the (re)construction of Portuguese contemporary city. The case of the Porto metropolitan area waterfront

Rodrigo Coelho

CEAU (Centro de Estudos de Arquitectura e Urbanismo), Faculdade de Arquitectura da Universidade do Porto, Via Panorâmica S/N, 4150-755 Porto Portugal.

E-mail: rodrigo.coelho@arq.up.pt

Abstract. *Due to the fragmented and discontinuous spread of urbanization, the Portuguese and European cities have seen over the past four decades their urban condition profoundly changed, resulting in the mangling and mutation of the urban landscape around the main urban centres, and in the weakening of the role of public space in structuring new urban expansions. Considering this background, and given the lack of consistent models or paradigms to intervene and design (or plan) the city today, will seek to question if, and how, is it possible continue to confer a “shape” to contemporary City from public space, particularly in its more recent and less consolidated parts (questioning also the nature of that hypothetical ‘shape’). We will seek to highlight the role that the project of public space can (still) play in building the ‘shape of the contemporary city’, recognizing it as a system of spaces with urbanisitic, formal and functional qualities, able to provide meaning and identity to the urban space, and able to restructure and support the growth of the city. Based on this understanding, we will defend (as an hypothesis), the need to consider the project of public space from the concept of urban fragment (recovering the importance of the urban project as the most consistent and appropriate way to approach an intervene in the city), seeking to recognize and systematize (using as case-study recent portuguese public space interventions), the purposes, the methodological principles, and the key architectural and urbanistic criteria which may recover the strategic importance of public space project in defining the ‘shape of the Contemporary city’.*

Key Words: contemporary city, urban design, public space project, urban waterfront

Introduction

Due to the expansion and fragmentation of cities, especially over the twentieth century, the relevant fact we consider important to remark, is the progressive and unstoppable process of disaggregation (both physical and conceptual) between the concepts of city and public space that, until the nineteenth century, were permanently interconnected (if we consider the public space as the one that condensed organically the political, economical and social space).

On the other hand, due to the fragmented and discontinuous spread of urbanization, the Portuguese and European cities have seen over the past four decades their urban condition profoundly changed, resulting in the standardization and disruption of public spaces and urban landscape around the main urban centres.

Taking into account this situation, the general question that this paper will seek to address is the extent to which it becomes possible to confer an exceptional character to urban public space in a time where urban societies seem to claim more individualized, more specialized and more enlarged forms of public space.

How can we design and build these exceptional public spaces in these parts of the city? And to what extent are these singular public spaces relevant to the shape, growth and consolidation of the city of the future, such as structuring components of possible systems of public space in more distended and enlarged urban contexts?

(Re) Shaping the limits: the rediscovery of urban waterfronts as exceptional “public spaces”

It is in this context that we consider key the interventions in the waterfronts, as well as, a reflection on public space projects that materialize these urban operations, and which in recent decades have been developed, particularly in the European context.

We are particularly interested in the examples where we can recognize the architectural and urbanistic attributes able to value these significant and memorable urban spaces, in the sense that they may rescue a collective dimension within a broader metropolitan reality; but we are also interested in those examples and projects which, by considering the geography in its physical concrete dimension, allow the natural elements to project, once again, as an integral part of the development and structuring of the city (rebalancing simultaneously the relationship between man and its natural environment).

The first and possibly the most important problem that arises in these cases to the public space's project will be the ability of intervening in these places (usually of great environmental value) taking into account morphological, urban and geographical characteristics.

The relationship with the natural and geographical elements tends, therefore, to assert itself as the central problem, which, from our point of view, should precede and influence the choices about the character of the program of uses of these public spaces. As Carlos Martí reminds us, if there is something permanent in the city, it is the presence of places, which by being “deeply urban”, simultaneously reveal a “strong bond” with geography.

The second topic, which we think is vital in the design of the “singular public space”, it is the recognition of these spaces as “significant and strategic voids”, open to collective appropriation, whose main attribute should be recognized in their urbanistic, landscape and spatial qualities.

Furthermore, the third key issue we consider critical to consider in urban waterfronts public space design, it is the ability of these urban projects to operate deep changes in strategic sectors of the city, trying to “shape” and “structure” the city (being aware that is impossible to control the shape of the city globally, but on the other hand we can not give up giving a shape and a structure to the city), while giving answers to the problems and concerns that each society poses particularly to public space.

The Porto Metropolitan Area Waterfront: a case Study

With respect to its waterfront, the Porto Metropolitan Area coastline has undergone, especially in the last four decades, a growing urban pressure, due mainly to migration from the interior lands to the coast of the country, that began in the 50s and 60s, and have become more critical in the years 70 and 80.

These dynamics have transformed these sectors in urban areas with considerable use conflicts, leading to a disqualifed and uncontrolled growth, namely on rural pre-existing meshes. In the case of Metropolitan Port this occupation took place, initially, especially with the construction of single family houses (in many cases with a illegal genesis) and more recently with the construction of multi-family dwellings and / or gated communities, supported by relatively poor infrastructures, resulting in the saturation of the use of the waterfront, increasingly pressured by the real estate market.

As a result of this occupation, the urbanization process of the coast has quickly reached a critical stage, that one can see reflected either in terms of the poor quality of roads, public spaces, and urban fabrics, either on the dilapidation of natural resources and landscapes: pollution and degradation of beaches and water lines, destruction of the primary dune, illegal occupations, anarchic parking, etc..

Similarly to numerous port and coastal cities, this cycle of abandonment and degradation also suffered, in the case of AMP a reversal in the 1990s (albeit with a few decades of delay

compared to the first European and American similar examples), which can be proven by the authorities recognition of the potential redevelopment of waterfronts.

In the case of the Porto riverfront, this redevelopment also followed the logic of requalification of major European examples - implementing special projects to develop these strategic areas. That is, taking advantage of exceptional urban renewal programs in order to streamline and enhance the convergence between the financial effort and the political will.

We are referring to the projects and exceptional interventions which not only were crucial to the successful regeneration of key urban sectors, but also become relevant by the project methodologies, and by the (strategic) design options adopted for the materialization of the public space, enhancing a consistent development, and a key role in the structuring of some important urban coastline sections.

These interventions, were mostly carried out (or at least completed) under the Polis Program (National Program for Urban Rehabilitation and Environmental Improvement of Cities, launched in 1999 by the Portuguese government), and took place in the three major municipalities that constitute the Greater Porto Area (being in the case of Porto and Matosinhos physically articulated, and constituting in the case of Gaia an "hinge intervention" which articulates the river front and the sea front).

In line with the premises and strategic objectives adopted by the Polis Program, it was adopted as a fundamental principle of the Polis Program intervention methodology, the elaboration of detailed or urbanization plans, in order to promote, systematically, the technical integration of urbanistic, environmental and design of public space design aspects.

In the specific case the seafront of Porto Metropolitan Area (AMP), the richness and interest of the projects developed under the Program Polis is strongly marked by the intention and consciousness of valuing waterfronts, as an urban and architectural theme, able to contribute to the transformation and consolidation of the shape of the contemporary city, giving it a structure and a global shape (albeit resulting from different urban materials, and different processes/dynamics of city construction).

However, it is perhaps this diversity of shapes and designs, guided by a common purpose - "make city" - (understanding simultaneously the context in which the urban project operates, and understanding the specific and structuring role that interventions on public space can induce in each specific intervention) which makes the analysis of the Porto Metropolitan Seafront even more rich and stimulating.

We do not intend to make here an exhaustive description of the projects and works undertaken. We are, above all, interested in explaining the extent to which a correct (pre) definition of certain purposes, and the adoption of specific urban design criteria, and specific forms for the public space of each intervention, were key in the overall success of interventions; as we also believe it is important to demonstrate to what extent the coordinated and comprehensive conception of these projects was essential to provide a structure and a form to the metropolitan city, being equally sensitive to the specific contexts and geographies of the places where these interventions took place, and responding simultaneously to the dynamics and uses that society claims to public space.

Moreover, will seek to analyse these interventions, and their contribution to a critical review and analysis of the public space project in exceptional areas, as well as a reflection on the definition of the form and content of public space within the more unstable current city; particularly with regard to the ability to create and claim (simultaneously) principles of order, diversity and vitality of urban public space from the renewed consideration of the relations between geography, infrastructure, topography and pre-existence.

In fact, the three interventions to be analysed tackle a difficult and demanding balance between factors of different nature, which is embodied in a coherent synthesis "built form" that does not deny or hide the many roots that "emerge" on the surface of a reality that the authors - use as a matter of project.

From this confrontation and compromise with the existing urban realities (territories without very clear rules), the interventions that were held on urban public spaces thus result in

consistent proposals, able to boost (in the medium and long term) important changes, assuming the construction of the city (and of the public space) with clear urban intentions, through precise and (re)founder gestures, able to exalt the qualities of the sites.

Empty vacant. Redefining interior's block voids in Guimarães

João Martins Dias¹, Rita Ochoa², Maria Candela Suarez³

E-mail: diaojoas@gmail.com

Abstract. *This paper aims to analyse how urban form can influence the configuration of a project, based on the thesis "Vazios devolutos – reinterpretações arquitectónicas em quarteirões do centro da cidade de Guimarães", held at the Master Degree in Architecture from the University of Beira Interior. From a methodology strongly based on the contact with the territory, through both insightful observation in situ and their respective experiences, as a rigorous analysis of urban morphology, later graphically systematized, were carried into space: dubbed the "central block". It was also investigated the current needs of the space, upon which was developed a subversion draft of the interior structure thereof. After parallel analysis of current shortcomings in the city, a program based on two fundamental assumptions was built: i) increased parking lot space and; ii) the introduction of public green space in the urban environment. The urban analysis will determine the resolution of the project, whether by the underground floor (parking), that after a "cleaning" of vacant buildings inside the block, it presents itself as a negative of the new configuration limit, transposed to a new level; either by the ground floor (public green space), which sees in all its new extension a green flooring, occasionally marked by "carpets" of different materials originated in the new areas of trade perimeter of existing buildings on the block, as conjugates the memory of old servitude pathways.*

Key Words: *Guimarães, historic center, block, empty vacant, architectural reinterpretation*

Introduction

One cannot propose an intervention on an historic city as Guimarães without having in account: its people, its (mostly) urban heritage preservation, about preserving the identity and the patrimonial authenticity, or the continuity of essential long-term continuities or even on the vernacular architecture. It is also important to be able to deal with the integration of new ways of thinking, new opportunities.

The responsible agencies for developing urban strategies on Guimarães historic city center rehabilitation defended the ban on demolition over concrete, safeguarding the city image, and "forcing us" to [re]think today intervention in the area.

The characteristic protection of the intramural area on which the Guimarães historic city center is in, is translated to the way the streets and the buildings around appear. The block's backyards and the urban voids of this tight and special urban fabric are not exception, presented then closed upon themselves, surrounded by secular national heritage and punctually on vacant state.

This paper has as main objective the study of the distribution and of the configuration of the sets formed by blocks and their intrinsic "empty vacant", in Guimarães historical center, as well as a proposal of an architectural reinterpretation of a specific block.

Urban morphology: the block

The object of study – the block – is the main element on the reflection around the reading and understanding of city's image. It as an element that can generate and be generated by the urban fabric. Costa (2013: 123) points out its importance in "*the local implementation of certain*

model of society, in the design of lifestyles, and in the conformation of the space and of the architecture that builds the city”.

In order to understand how the city blocks appeared in our cities, and influenced its urban fabric, it was explored a theoretical framework, on “urban morphology. The block” theme was carried on, through: 1) individual/comparative analysis and studies; 2) case studies in different cities.

The first analysis aimed the block as a morphological element of the city: a) the generic definitions of the block itself; b) setting its morphological elements; c) and its typological evolution.

The morphological elements of the block

Assuming that architecture is what gives form to cities, and following theoretical urbanism planners, the morphological elements of the block are (Lamas, 2011): a) the street; b) the façade; c) the building; d) the backyard (Figure 1).

Figure 1. Morphological elements of the block: street, façade, building, backyard (author’s scheme).

Typological evolution of the block

In order to understand the contemporary blocks, we used a typological evolution of it, as an understanding tool. So, we chose 6 types, that represents the major changes through time: the greek block, the roman block, the medieval block, the renaissance block, the industrial block and the vertical/modernist block (Figure 2).

The morphological evolution of the block over time was either associated with its urban evolution, or with the urgent need to rebuild the city.

Figure 2. Typological evolution of the block (author’s scheme).

When it comes to issues of permeability, geometry, public/private, and the use of the limit perimeter area and its interior, the configuration of different types of block and its interior space is a literal response to the needs of the time. Although it is a complementary space, the backyard plays a peripheral extension of buildings, without liability to the public space. The intervention in an area with these characteristics must be taken as a new way.

Case studies

This part of the investigation consists on the identification and the interpretation of a set of case studies, which in their nature include a physical occupation of the block where the interventions

have a subversion of the regular structure of the interior of the block. The four examples were chosen according criteria of differentiation in the settlement of the block itself, including its permeability.

This analysis does not aim to make a complete presentation of the project but make known types of intervention of this type of sets, adopting a graphic and abstract analytical model.

In order to arrange these examples, an identity characterization (a keyword) was created, for each one. This analysis has in account key points such as ‘densification’, ‘flow’ and ‘permeability’ of each case.

“Preservation”

Guimarães urban development**

The intervention in a pre-existence requires an attitude of preservation. The preservation of cultural and historical heritage of a city retains the longevity of the memory of the local people and the actions and interventions in this, are what shape it and keep it “alive”, through time.

The study of Guimarães’ urban evolution is intended to help in conducting a clearer thought and action.

Mattoso (2002) identifies 6 different stages on the evolution of the city (Figure 7): 1) the “Bipolarization” (950-1279); 2) the “Gothic union” (1279-1498); 3) the “Renaissance, Mannerist and Baroque Requalification” (1496-1750); 4) The “Rococo, Pombalin and Neoclassical Reform” (1750-1863); 5) the “Eclecticism and Industrial expansion” (1853-1926); 6) the “Modern-monumental magnification and renewal” (1926-1974).

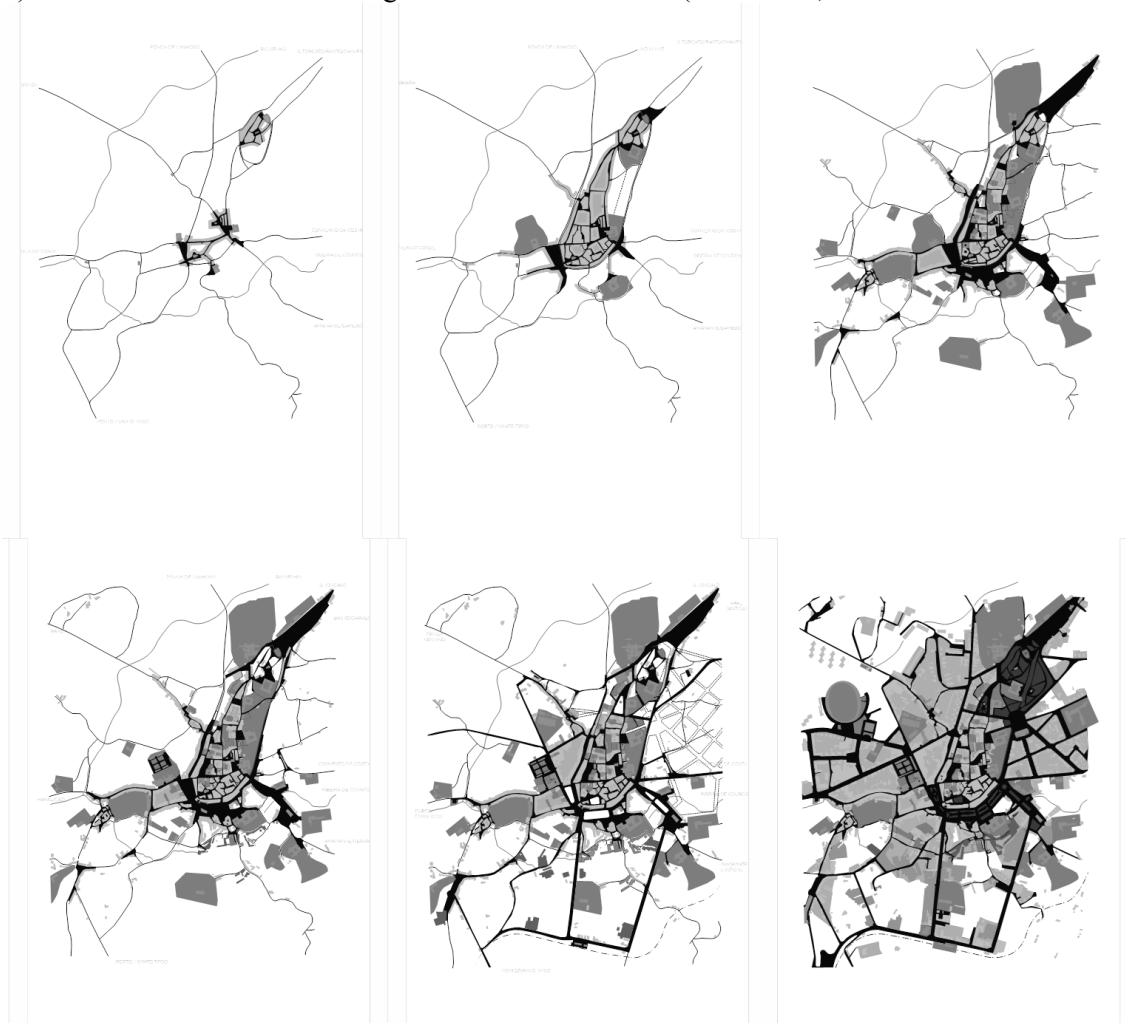

Figure 11. Urban development of Guimarães (author’s scheme).

The contemporary city

Since 1985, and as a response to the management of the recovery process from the historic center, Guimarães has a municipal office responsible for this task (a.k.a. GTL).

Along with the recovery process, the objective of maintaining the resident population and the preservation/restoration of the authenticity of the ways to intervene in the heritage, make part of the scope of GTL. It was intended that operations undertaken by GTL had an exemplary character, thus constituting pedagogical instruments and incentives to private enterprise in the rehabilitation of the historic center.

The GTL, through both internal and central government financing, has structured a set of action that, in addition to the buildings, also focuses on public spaces as a method to induce private capital investment in buildings of those areas.

According to the City Council, while maintaining a specific character of the different epochs of the evolution of the city readable in various architectures, registration matrices and new designs of public spaces, interventions in public spaces gives them greater dignity also through the introduction of new infrastructure structures.

Through the rehabilitation of public spaces, squares and wide streets are returned to the city and to its inhabitants and visitors, that with the continued growth of the city had turned into chaotic parking spaces. Currently, 90% of intramural public spaces are already rehabilitated, mainly areas for pedestrians, motorized pathways and streets with side parking areas. These actions constitute a valuable contribution for the authenticity that has maintained/replaced but also to reinstate the historic city as a cultural meeting place with self-identity.

But Guimarães city council also reports all the current problems in the city, in order to show their future intentions and to improve inhabitants' quality lifetime.

Two of them that captured our attention, due not only to high priority need of action: the lack of public green spaces in the city, as well as the lack of parking spaces.

Intervention – proposal for new green public urban space and parking lot inside a block

The last part of this paper aims to present a practical response to the problems previously reported in the city of Guimarães. The methodology for this part lays in the characterization of the site, through a morphological analysis of the object of study, the presentation of its current status and then the presentation of the intervention developed.

The project-oriented approach as a result of the combination of the initial phase of theoretical research of the evolution of the block, with the analysis of four case studies; the urban development of Guimarães; and the account of the current problems of the urban fabric (lack of green space and parking).

This consists in the development of a strategy for rehabilitation of block voids that pretends to be a plan to revitalize these spaces, applied at an early stage to a single block, and should be understood as a starting point and help for future analysis or proposal development. This strategy is intended to be extended and applied to other city blocks.

As mentioned before, the city of Guimarães suffered a major investment in infrastructure level on time of industrial reform (1850-1900) and therefore a large and disproportionate growth to its peripheral area.

The peripheral expansion relieved not only the city center traffic, but also, with the construction of new public use equipment, the city center importance, that lately started being uninhabited, started decreasing.

Guimarães is also characterized by a strong investment in traditional trading and has gradually suffer from this problem, manifesting itself not only by the abandonment of inhabitants of the historic center, but also of traders disgusted with the lack of movement and high rates rental of their stores.

The programmatic objective of the intervention enshrined as fundamental points of intervention: 1) the cleansing and revitalizing the 'core' of the block; 2) recovery and increase of green areas; 3) systematic urban rehabilitation unit; 4) improving relations with the traditional trade; 5) the introduction of parking lot space; 6) to be a future recovery booster of existing buildings with architectural interest and value.

The “Central Block”

The block that was chosen to be intervened (Figure 12) is located in the central area of the city, in the parish of São Paio, develops in approximately 2.48 ha and is bounded by the following arteries: Rua de Santo António; Largo Navarros de Andrade; Rua Gil Vicente; Rua Paio Galvão

or trade, but also occasionally by vacant buildings. The fact that the object in question has old servitude paths in its interior, was also a configuration criterion for the choose. Openings are “tunnels” that tear ground floor buildings, in order to access its interior and to enjoy these shortcuts (even if you have to “break in” some private properties).

Current situation

The “central” block consists of 68 buildings. Apart from these, there is an amalgam of others, which were built by the owners of the first ones - sheds, outbuildings, factories (now made car garages), warehouses and paths of servitude - sometimes as an extension of own home, or as support for other activities (Figure 14).

Figure 14. Layers of constructions on “central” block (author’s scheme).

As demonstrated above, the 'central' block is permeable, to the extent that there are now ways of public servitude which are understood as shortcuts between streets opposite the block. In addition to the permeability question, are the constructions on old backyards (which can be difficult to access by other inhabitants) that will be shown below (Figure 15).

Figure 15. Example of access tunnels to the blocks’ interior (author’s photographs).

Cleaning

The first step after an analysis of the block and of its elements, towards the intervention, the main objective was to building the 'core'/void of the same. Considering first the nature of them - the fact that they were built in ancient spaces, or appropriations by the perimeter buildings - and later its uses, it was decided (by the author), the total demolition of the same (Figure 16). Since hennery, to vehicles garages, or even a factory quenched with approximately 2000m2 area of deployment, these buildings are strongly characterized by a poor state of repair.

Figure 16. Axonometric representation of final block cleansing (author's drawing).

Proposal

The proposed revitalization for the block is, as previously stated, the resolution of problems of the current urban fabric. The configuration and location of the studied block, along with the introduction of the new program, allows not only to reclaim unused spaces; it also aims to improve the day-to-day lives of residents / visitors; the enhancement of the existing public space; and a better relationship with traditional commerce (via their ennoblement, or the strengthening of its symbolism and historical identity).

The constructive concept basis of the project shall take the cleaning done in the 'core' of the block and transpose it to the new underground car park. Through this step, the interior facades of buildings are delimiters, while defining identity to the new space, with only adjustments in nonsense situations (Figure 17).

Figure 17. Ground level and underground level configuration (author's drawings).

This action of extending interior façade walls' base lines few meters below ground bring the block to the park, although underground and away from all outside movement, has its limits in an urban form common in the city of Guimarães – the irregularity of an urban front.

Admittedly, and as a further attempt to return old living spaces to the block's interior, the natural slope of the ground floor terrain was also transposed (distance parallel) to the floor of the new parking lot. This decision facilitates access to the park because all the ramps have the same slope, since the height inside the park is the same regardless of the dimension of the street outside we meet up.

The block's permeability, previously marked by informal access, now becomes a key point in the project. The old tunnels have now been improved, allowing not only direct pedestrian access to the interior of the block, as they are ramps to the underground floor.

As mentioned before, one of the criteria for choosing this particular block was due to the fact that the entire ground floor is occupied by buildings devoted to commerce / services. This applies now in the proposal stage, to the extent that, by making the 'core' of the low block accessible to all, being totally clean, allows all buildings of this type to gain a second front for the public space. In the case of these spaces are buildings dedicated to commerce, the new front opening allows a new area available for opening terraces, which in all cases is not possible for the outdoor street. These buildings are now referred to as "carpet-buildings".

The ground floor urban treatment consisted on pavement processing, green landscape, permeable entries and vertical access boxes to the car park. Also in relation to commerce-dedicated buildings, these were chosen as the subject of another of the main concepts of the project – “the carpet-buildings”. As the natural unfolding of a carpet after its acquisition, from the back (interior façades of the block) of these buildings, a different pavement arises, guided by the limits of each building, until the building on the interior block opposite façade. This space is essentially reserved for the placement of these terraced buildings (Figure 18).

Figure 18. Urbanistic treatment of ground floor (author's drawing).

The used materials intend to continue the identity and the memory of the ones used originally around the block. We are faced with three different types of materials: cobblestone, screed and lawn.

On the ground floor level, almost all of the area, resort to the use of gardens, that are being cut by the 'carpets', initially 'unfold' of the rear of the buildings in cobblestone, changing to screed, when in turn, these intersect the openings for natural underground lightning on slab (Figure 19).

Figure 19. Openings for underground natural lightning (author's drawings).

The slab dividing the two levels work as a dual structure: a first that connects from the block's buildings and stops in tears and a second (larger) to complete the entire interior of the “core” of the block. Both work as green roofs, planned to drain away rainwater (Figure 20).

Figure 20. Final ground floor solution (author's drawing).

Conclusion

With the developed proposal, we had shown how urban form can influence the configuration of a project. This proposal also raised important issues related to the experience of contemporary cities, including the appropriations and the uses to which its inhabitants make of urban spaces.

The abandonment of the historic centres by their users, situation that belongs to a cycle connoted with political, social and demographic change, causes morphological structures, their heritage, their identity and its people, to be forgotten and only recorded in the memory of those who lived them.

In the case of a city such as Guimarães, which has agencies responsible for developing strategies for the historic center; and for which interest has been shown (first with the appointment of Cultural Heritage by UNESCO ®, then with the European Capital of Culture, and more recently with the European Capital of Sport), as well as investment, this process has to be caught and new solutions created.

One of the solutions addressed in this paper involves the raw analysis to places that lost their identity over time, either through lack of interest, or a wrong appropriation. This results in problems that need to be clogged, in order to give back its initial strength.

The specific case here focused, in which a void of a completely uncharacteristic block, became not only a driver of change in the surrounding, as returned strong past development factors, helped us to realize how a city dweller can respond to a series of reported problems, turning it into a future high interest practical application.

Reviving the heart of a historical metropolis: Comparative study between different urban forms in downtown Cairo, Egypt

Kareem Adel Ismail

School of Architecture and Planning, National Institute of Creative Arts and Industries
University of Auckland, Auckland, New Zealand. E-mail: kism817@aucklanduni.ac.nz.

Abstract. *In a historical Metropolis like Cairo, where 20 million people live in a city with more than 1000 years of history, many social, economic and environmental problems arise, threatening the historical heritage and the unique urban form that the city have. Downtown Cairo area including Tahrir, Attaba and Opera squares as well garden city area are clear example of this dilemma; these squares and surrounding areas located in the heart of Cairo have suffered from continuous deterioration through the last three decades, with a wide range of complex problems ranging from spread of informal markets, traffic congestion, and most significantly loss of cultural historical values. Through this paper, researcher investigates the existing challenges and issues facing these areas, comparing between its urban form patterns, usage and its effect on the heart of the historical city. The collected data about the current conditions and resident's problems were partly gathered through survey, site visits, and visits to responsible authorities. Data analysis showed that the difference between urban forms between areas is also related to socio-economic and functional aspects. Those aspects raise the need for an integrated urban design proposal which connect between these different urban patterns to solve the congested downtown area problems, with consideration to the continuous radical changes to the function of these areas due to socio-political circumstances. In conclusion, the researcher relate between these areas through integrated urban design trying partly to solve part of the main problems facing downtown area and preserving its rich cultural and historical heritage.*

Key Words: *Downtown Cairo, Tahrir Square, integrated urban design, historical conservation.*

Introduction

The city is the peak of human civilization and the optimal model to represent the human settlement, and any nation's civilization could be measured by their protection of history and the renaissance of their cities.

Cairo is a clear model for this statement, it is not only the capital of Egypt and centre of government, but also considered the biggest metropolitan centre in the middle east, with more than 16 million inhabitants (Egyptian statistics agency, 2006). In addition Cairo is considered as well as a major centre for trade located in the bottom of Nile river delta as shown in figure (1) and also as a well-known tourist destination where wonders of the Egyptian Civilization throughout all its different ages exist.

Cairo as a city with over one thousand years of civilization since its establishment in the reign of the Fatimid state has passed through several changes. One of the most important of these changes is the developments made by Khedive Ismail ruler of Egypt in the late nineteenth century when he wanted to turn Cairo to be Paris of the east, inspired by his French education and preparing the city to be with European flavour to host the opening ceremony of Suez Canal in 1869. The Khedive constructed downtown area including Attaba square, Khedival opera house, Opera square and Azbakiyya Garden with lots of iconic buildings designed by famous Italian and French architects (Aga Khan Trust for Culture, 2004).

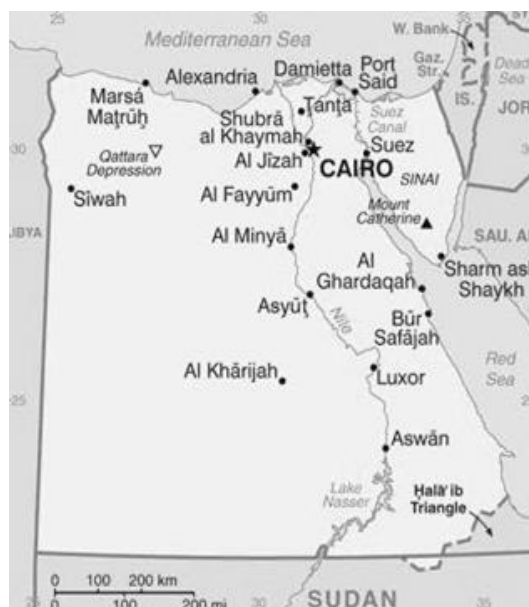

Figure 1. Map of Cairo location within Egypt. Source: University of Texas Library (2013).

Since that date in 1869, the importance of Attaba and Opera area has increased rapidly specifically during 1940s, when it became the real cultural heart of Cairo with the presence of the opera house, national theatre, cultural cafe and cinemas all in one place, surrounded by Islamic monuments from the east and Khedival downtown from the west. During 1940's, Tahrir square (known in that time as al-ismaelia square) was constructed as a place to memorize Khedive Ismail. But it became more important as Tahrir Square was the focal point of political change in Egypt in the last three years through 25th January revolution and its continuous waves, plus that Garden city area constructed around the same time was initially designed to be a place for foreigner diplomats with lots of villas and circular shaped streets

Therefore, focus of this paper will be on Downtown Area highlighted, Attaba /Opera squares area highlighted in green and Tahrir/ Garden City area highlighted in blue as shown in map (2). Furthermore, Cairo overall have passed under some massive changes during the past fifty years, but specifically downtown including Tahrir square, Attaba/Opera and garden city areas has suffered from continuous deterioration of the heritage buildings and the urban form.

That deterioration of the urban form is mainly caused by absence of integrated management of the site, spread of informal markets, traffic congestion pressure and the continuous crisis of the Egyptian economy in the last 20 years.

The paper starts with explanation of used methodology, the theoretical framework followed by morphological analysis of the selected sites in Downtown Cairo area, then comparison between the urban patterns of the sites based on literature review and finally reviewing of the urban renovation projects in the area and ways to integrate between them.

Methodology

A comprehensive methodology is adopted to investigate the existing issues in the area, comparing the urban forms of the different sites leading to formulation of integrated design solutions based on existing and future urban renovation projects. The methodology is based on usage of multiple sources of evidence which are a) fieldwork- survey with different users in Attaba and Opera area including residents; b) observation of the sites current conditions; c) semi-structured interviews with officials from different agencies responsible of the area to get data and their views about the study area situation like (traffic department, antiquities council,

Cairo governorate, etc.); d) different documents from literature about Downtown Cairo development.

Putting into consideration that paper is focusing on Downtown area through reviewing of the revitalization of Khedival Cairo project made by al-ismaelia Company, as well Attaba and Opera squares as it was the study area for a design competition won by the author early 2011. However Garden city area analysis is totally based on aerial maps.

Figure 2. Map showing the case study sites. Source: Map edited by author, extracted from Google Earth (2014).

Morphological analysis of urban pattern for case study sites (Downtown, Attaba / Opera squares, Garden city)

As mentioned by Batty (2008) urban morphology is described as the patterns of urban structure based on the way activities are ordered with respect to their location, based on that definition Downtown Cairo sites with its urban systems is an interesting area for analysis. Mainly because of the different patterns that exist in these areas and how they are connected together. The analysis focus will be on a) Socio-economic changes in the sites, b) Traffic and pedestrian movements, c) Land use and urban pattern and how all of these layers effect on the urban form.

Downtown (wust el balad)

Since its establishment in the 70's of the nineteenth century by Khedive Ismail, Downtown area gained increasing importance from begin the only downtown of historical Cairo where people need to pay to cross Kasr El-Nile bridge to reach it, designed like Paris with roads and wide pedestrian walkways, to be by in the beginning of 21st century one of many downtowns in metropolitan Cairo and centre of government, trade (place of stock market) and vibrant informal markets (Jean-luc.1993).

History

The area with its 160 years history, have gone through many phases which could be explained as follows; a) Construction "attraction of uses" which was during 1870's till World War I, where the elite families and foreign diplomats owned most of the houses in the area specially after British occupation of Egypt in 1882. These foreigners and other residents try to imitate the European life style through urbanisation within the area which increased significantly between 1874 in figure (3) in comparison with status in 1896 in figure (4).

Figure 3. Downtown map in 1874.

Figure 4. Downtown map in 1896.

Second stage between 1919 till end of royal era in 1952 which could be called b) Booming stage, affected by 1919 revolution and reforms in first elected government in 1924, accessibility of the common Egyptians to the area increased as well the economic activities in Downtown, that trend continues till it reached a peak point during World War II, with European immigrating to Egypt, specially Cairo and Alexandria escaping from war, where the Egyptian Kingdom in that time was a safe paradise with stable strong economy for their businesses, where the uses enriched the urban pattern (Jean-luc.1993).

These factors plus innovation of cinema made Downtown centre of entertainment with lots of shops, cinemas and became vibrant centre of culture and shopping destination for elite after 1952 revolution against the royal family and departure of King Farouk. Downtown under revolution rule faced some major changes in its socio-economic structure of residents, where Europeans begin to leave the area and Egypt, scared from political change and socialism

Table 1. Users perception of problems and preferable solutions in Downtown area.

User category	Main problems	Needs and preferable solutions
Residents	The street vendors occupying the area, no recreational places, high traffic congestion	The restoration of historical buildings Transfer of street markets outside the area Give priority for reusing of public spaces rather than commercial activities.
Vendors and Merchants	No stable place for street vendors, negatively affecting the big stores	Design markets that have permanent place for street vendors, free the facades of the main stores from any additions or constraints.
Passengers	Crowded pedestrian ways, Street vendors destroying the pedestrian experience	Transferring street vendors outside the walkways and squares, usage of more traffic signs and renovation of historical buildings
Tourists and others	No services either in accommodation or transportation, plus no care for cultural sites.	Redesign of walkways, preservation of the cultural/ historical sites. Improving the transportation and controlling the informal markets occupying pedestrian walkways

Transportation and pedestrian movement

The traffic movement in downtown area is depending on five main routes for pedestrian and vehicular traffic and where most activities which are 26th July, AbdElkahikSarwat, TalaetHarb, Kasr El Nile, Mohamed Sabri streets highlighted in blue in figure (7). Where traffic using Downtown area to transfer from Tahrir square to Islamic Cairo, Attaba / Opera either through roads or underground metro (Zakaria, M & Institute For International Urban Development, 2010) Although of the radial grid of streets, but the rapid increase of traffic volume is obstructed by informal markets and affected the heritage buildings, which create a major traffic congestion problem.

**Figure 7. Downtown pedestrian and transportation routes map.**

Land use and urban pattern

The land uses is totally related to urban form, figure (8) show the spread of commercial uses, hotels, banks, cinemas and governmental offices around the main routes previously mentioned. It could be observed through figure (9), the main routes highlighted in blue with around 9 meters width, secondary routes in yellow with around 6 meters width and how both of them connect between main squares (red circles) and minor intersections (blue circles). This radial grid divided the area into four main precincts, with minor differences in uses, block sizes and walkways.

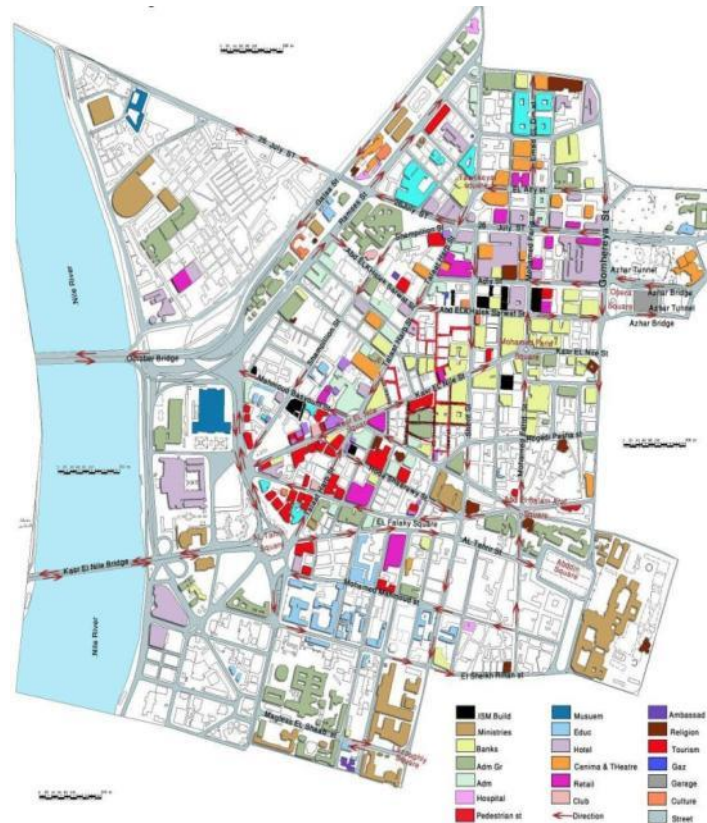

Figure 8. Map of Downtown land uses.

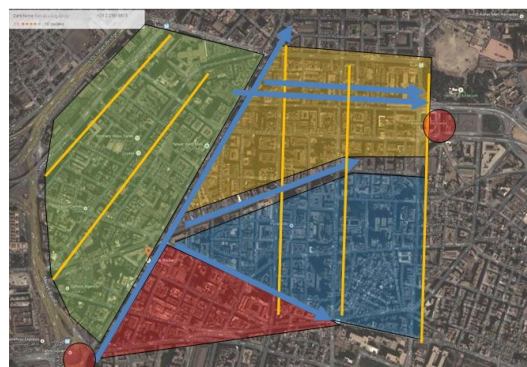

Figure 9. Map showing Downtown urban pattern.
Source: map edited by author, extracted from Google Earth (2014).

Attaba & Opera Square

History

Opera square was constructed during the khedival era where the opera house was constructed in 1869 to memorize the international ceremony of Suez Canal official opening. After a while in 1891, the square changed by transferring Ibrahim Pasha Statue from Attaba to the centre of the new square, in front of opera house to make a landmark of the square in the end of khedival Cairo. Due to the square importance, a hotel named “New hotel” was constructed in front of Azbakiyyah Garden. The square as part of down town so it develop more and more services were constructed nearby it like Attaba telephone central in 1962 and it became important culture transportation space in 1960's (El-Messri, N.,2004).

Attaba square is considered the oldest commercial square in Cairo, since establishment of Azbakiyyah area around the Baraket El-Feill (occupied the area in the Mumluk period). In the Khedive era, a palace was constructed called (Attaba El-Khadria) as a part of modernization plan for Cairo. There were two streets in 1860's one from the north of the square (Attaba Street) and one from the east (Moskhi Street), Then Abd El-Aziz street opened in 1869, followed by Mohamed Ali street in 1875, Prince Farouk (now El-Gheish street) in 1927 and lastly Al-Azhar street in 1930 (El-Messri, N.,2004).

Then the square was formed since then with its present shape, and its importance increased rapidly due to some factors, as follows: The existence of unplanned popular markets (El-Moskhi market) as a commercial potential point between El-Gheish and Moskhi streets, The square being the main centre of transportation trams in beginning of 20th century (as it was the main transportation mean that contact Cairo area with each other through Attaba central station), Destruction of Mixed Court main building which create free space for the square formation as it is now. Existence of many important culture cafes like (Mattatya, Khedive, glass...Etc) where famous great Egyptian authors and writers use it, Existence of many important buildings around the square like Fire station, Cairo Post office, parliament hotel and historical buildings between Mohamed Ali and Al-Azhar Street, existence of some culture icons like Azbakiyyah Theatre (now known as national theatre).

a) Socio-Economic conditions

The socio-economic structure of the area is totally related to the land uses and type of economic activities happening within the area. As shown in Figure 10 based on survey made by the author team, the main activities are entertainment followed by commercial and business, with variety of activities enriching the urban pattern. When related to user classification also shown in Figure 10 show that passengers and street vendors are dominating the area with conflict of interest with residents as shown in table 2 and different set of problems (Ismail, K,2012).

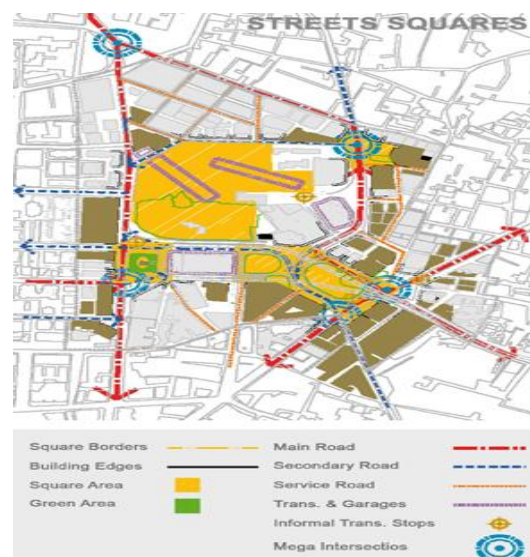

Figure 10. Showing main activities and user classifications in Attaba /Opera square area.

Table 2. Users perception of problems and preferable solutions in Attaba/ Opera squares

User category	Main problems	Needs and preferable solutions
Residents	The street vendors occupying the area, no recreational places, high traffic congestion	Restoration of houses, transferring street vendors to planned markets, and adequate transportation, reusing of public parks and design walkways.
Vendors and Merchants	No stable place for presenting goods, main stores are negatively affected by street vendors	Designed markets that have permanent place for street vendors and free the facades of the main stores from any additions or constraints
Passengers	No safe pedestrian ways and no efficient connection between different transportation means.	Designed walkways connecting between bus, metro and taxi stations in relation with Azibkyyia garden, and the two main squares
Tourists and others	No services either in accommodation or transportation, plus no care for cultural sites.	Adequate transportation services, usage of abounded hotels, improved services and re design of the cultural/ historical sites.

Transportation and pedestrian movement

The transportation congestion in the study area is clearer in points at the end of Downtown and start of Alazhar tunnel as shown in figure (11). The street network in Attaba and opera square is complex, where public, private transportation are mixed with pedestrian walkways creating high level of congestion. The transportation network include as well the underground metro station and lines, and an overfly bridge which connects downtown with Islamic Cairo.

**Figure 11. Map of Attaba/Opera transportation routes.**

Land use and urban pattern

As for land uses, as shown in figure (12), there is a mixture of commercial and residential uses. Beside those uses, there are around 15 listed buildings and cultural buildings as the national theatre; as well, two-multi story parking buildings exist instead of the burned opera house. The

Azzbakyyia park size and location create potential for development of the area to integrate between the main green space and surroundings urban blocks. The reuse of some commercial buildings for the favour of cultural aspect will regain its importance within Cairo fabric.

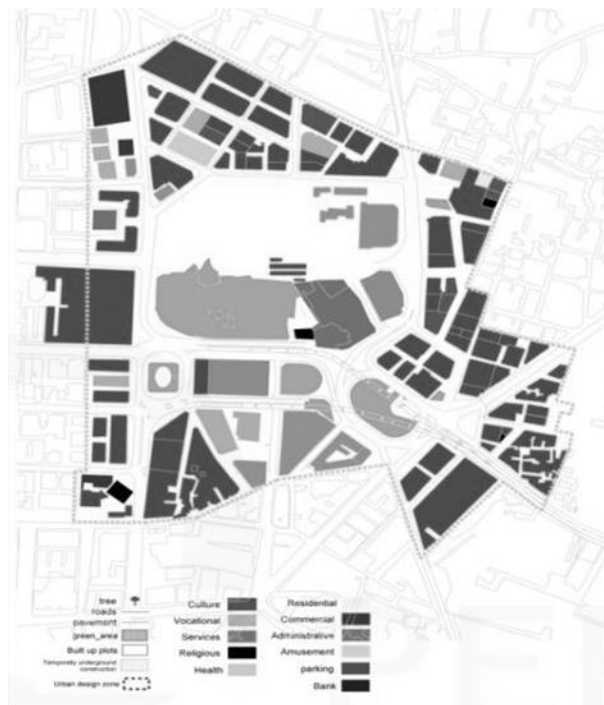

Figure 12. Map of Attaba/Opera area land uses.

As for the urban pattern as shown in map 13 the urban blocks highlighted in red around the squares still retain its original pattern. However, the rest of the area highlighted in yellow have changed to narrow width and irregular structure of streets that effect on the pedestrian experience and size of urban blocks.

Figure 13. Map showing Attaba /Opera urban pattern.
Source: Map edited by author, extracted from Google Earth (2014).

Garden City and Tahrir Square

Garden City was originally designed in 1906 like an English garden suburb to increase security and privacy for its residents. But since then Garden city area has not seen major changes in its urban structure since its establishment that is clear when comparing the urban pattern of the area

in 1904 shown in figure (14) and the current structure shown in figure (15). The circular wide streets dominate the pattern, enriching the pedestrian experience but decreasing the permeability and legibility of the area especially for external users.

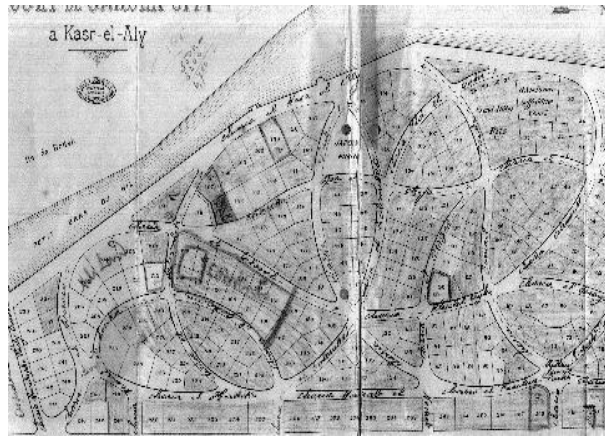

Figure 14. Map showing Garden city plan in 1904.

Figure 15. Map showing Garden city urban pattern. Source: map edited by author, extracted from Google Earth (2014).

. The location on the banks of river Nile made it place for elite Egyptian families' villas the area and for foreign embassies and diplomats due to the privacy that the urban pattern provide for the residents and amount of green space, with controlled linkage with Downtown and Tahrir square through Nile Corniche and Kasr el Nile streets (Attia, S. , 2011).

.Tahrir square in the other hand, have changes its function through its history since its establishment in end of 19th century, from being a beautiful plaza in royal Egypt as shown in figure (16) to be a vibrant public space where millions of Egyptians use as a modern (Agora) arena for political change as shown in figure (17).

.That purpose was clear in 25th January revolution were the square was a mini city within the heart of Cairo, redefining the space and usage of public places.

Comparative Study

SWOT analysis was made for the case study area which is shown in table (3); also the areas suffer from common problems which are as follows: high traffic congestion as the study area

sites are the centre of government, major trade hub and active political arena; deterioration of the urban fabric due to lack of integrated management and development pressures; increase of informal markets and uses, pollution, destruction of the historical parks and lack of green space areas; demolition of the historical listed buildings and significant cultural sites; rapid change in the socio-economic structure which reflects on the land uses and requires modification on the patterns.

Figure 16. Photo showing Tahrir square in 1940's.

Figure 17. Photo showing Tahrir square usage as a modern political agora.

Table 3. SWOT analysis of the case study areas

Area	Streets	Urban Fabric	Location	Example of the urban blocks relationship with streets (Urban Pattern)
Garden City & Tahrir Square	<p>The circular structure of the streets, decrease the permeability and legibility of the area.</p> <p>Effects negatively the accessibility of the users to some places, but allow a different pedestrian experience for users</p>	<p>The concentric grid of the area has helped to increase the privacy and development of residential activity.</p> <p>The pattern allowed spaces for wide walkways and sufficient green areas.</p>	<p>Proximity to the Nile River, as well to the governmental offices, kept the character of the area and its socio-economic structure. The current uses (embassies) have helped the isolation of the area from all surroundings.</p>	

Downtown wust el balad	<p>The linear structure of streets increases the permeability of the area and legibility of the historical buildings.</p> <p>This structure effects positively on the accessibility to/from the area, enrich pedestrian experience of the users.</p>	<p>The radial grid allows more opportunities for increase in buildings heights/ changes in uses and enriches the commercial activities.</p> <p>The design allowed space for walkways, open spaces, but less space for green areas.</p>	<p>The location as a transitional point between Tahrir square and Islamic kept the area as a vibrant downtown.</p> <p>Cinemas and uses increased rapidly the usage of the area, as well the political events happening in Egypt.</p>	
Opera & Attaba Square	<p>The irregular shape of streets decreases the permeability of the area, where urban blocks are totally irregular in shape.</p> <p>That effects on the accessibility and turned lots of the streets to informal pedestrian alleys and create lots of traffic congestion problems.</p>	<p>The irregular grid allowed the spread of informal markets and effect on the socio-economic commercial structure of the area.</p> <p>The street itself converted to be walkway with no open spaces or green areas with the urban pattern.</p>	<p>The location at the end Downtown and Islamic Cairo gives more importance to the area.</p> <p>Moskhi markets and other commercial activities, dominate the area above the cultural activities (national theatre), with lots of traffic congestion and informal markets.</p>	

b) Integrated Projects (Way Forward)

The Revitalization of Khedival Cairo

The goal of this project is to restore the cultural character of Downtown area, through restoration of the historical buildings and redesign of the walkways in the area to improve the pedestrian accessibility. These project master plan shown in figure (18), is mainly depending on turning some routes within Downtown area to be pedestrian only, improving main public spaces within the area like spaces shown in figures (19, 20) including Opera square. The project management and funding is through cooperation between private sector and governmental authorities, aiming towards the preservation of its valuable building stock and restoring its environmental quality.

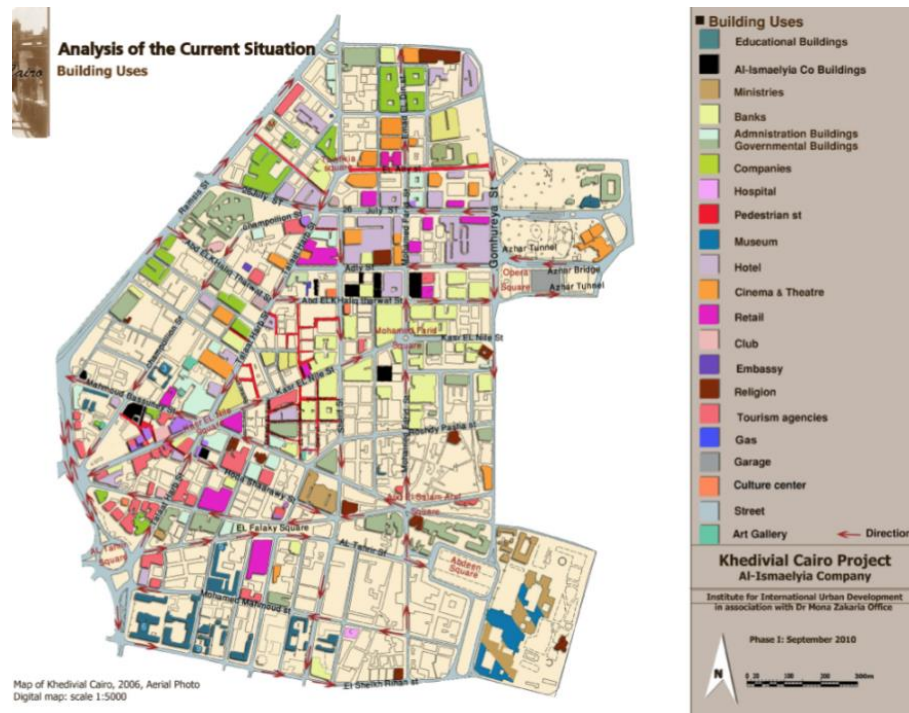

Figure 18. Master plan for revitalization of Khedival Cairo project.

The following four categories of interventions have been selected based on report by Al-Ismaelia for Real Estate Investments (Zakaria, M & Institute For International Urban Development, 2011):

1. Improving the pedestrian circulation network by- widening selected sidewalks and restoring segments of the through block pedestrian passages;
2. Preserving and restoring the facades of historic structures that have suffered from deterioration;
3. Restoring and maintaining the quality of the Area's many late nineteenth and early twentieth century landmark buildings, preservation of the urban pattern;
4. Regeneration of the area economics through presentation of the housing stock and development of the tourism activity (hotels and iconic character of the area).

Figure 19. Photos showing space in from to Cairo high court now and proposed future design.

Figure 20. Photos showing Opera square now and proposed future design.

Figure 21. Aerial perspective of proposed connection between Giza governorate and Downtown area. Source of photos (19, 21, 21) Attia, S (2011) the revitalization of Khedival Cairo, The Winning prize 2001 AC & AECOM

Attaba and Opera Squares “Heart of the Heart”

"Heart of the heart" is the proposed project theme which arises from the fact that Attaba area is considered the heart of Cairo, which is the heart of Egypt. While the main attention was to preserve the area and design the new opera house, it was more important to form an integrated sustainable vision for the area development, which includes both built environment and residents, not only preserving the past through restoration of the historical buildings, enriching the urban form and redesign the area, but also developing the quality of life for residents of the area.

As shown in figure (22), the concept is designed to address the area's problems, and that is through creation of four centres within the three main roads. The location of each centre is integrated with the uses in the surrounding areas, so the transportation centre is related to the Attaba metro station and in proximity to Ramses main train station and nearby Downtown area.

Figure 22. The project main concept.

Furthermore, the commercial centre include accommodating all street vendors using all free land and replacing deteriorated buildings in the north east point in well-designed markets to be as an extension of the Islamic Cairo markets, the business centre is considered as an extension of the business downtown area. The integrated transportation solution shown in figure (23) tries to create alternative routes for vehicular traffic outside the area.

Figure 23. Proposed integrated transportation plan.

And create two main pedestrian plazas (Opera /Attaba), the master plan shown in figure 24, clearly present the proposed development of a complex chain of regulated markets, that is through replacement and refurbishment of some ruined buildings adjacent to the area, and usage of some land-use space to create a developed market to accommodate the wholesale Moskhî market in a civilized manner that preserves the rights of these merchants (Ismail, K, 2012).

Figure 24. The project master plan.

The Azzbakyyia garden is redesigned in its original size after elimination of all buildings, all keeping the national theatre and the book market to be as a cultural park with an open space theatre in the North West side. The two squares are connected through pedestrian walkways; and the proposed urban patterns as shown in figure (25) are designed to reflect the new

character of the squares which is shown in figure (26) the aerial project perspective (Ismail, K, 2012).

Figure 25. Map showing proposed urban pattern.

Figure 26. Aerial perspective of the proposed design of Attaba/Opera square.

Tahrir square and Garden city future plans

The importance of the square have led many designers to reflect the vibrant character of the place through preserving the public open space and increase pedestrian accessibility to the area as shown in figure 27. However, some other examples focused on increasing the green space to be supporting spaces for the buildings around the square as shown in figure 28. But till now, no concrete competition or plan was made to redesign the square (ICARCH gallery, 2011).

Figure 27. Map showing proposed plan for Tahrir Square.

As for Garden city area, the unique design and existing land uses, has inspired the authorities and local non-governmental organisations to have minimal intervention in changing the area, but rather trying to preserve that unique pattern and connect it with the surrounding neighbourhoods. However, the continuously changing political situation have stooped all efforts to develop the area heritage sites, with evolving threats on the historical listed buildings (ICARCH gallery, 2011)

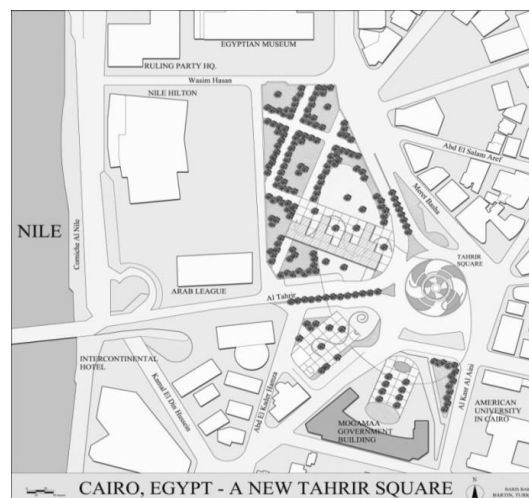

Figure 28. Another example of proposed plan for Tahrir Square.

Conclusion

The structure of downtown Cairo is really complex, populations increase, economic situation and socio-political circumstances add to that complexity. Also that urban form of these complex sites needs to be related to the socio-economic aspects of the residents, which should be included in any future integrated approach that tries to create sustainable, vibrant, and dynamic centre (heart) for the capital. Such centre that emphasis on the need of residents to a safe pedestrian environment with more efficient public transportation patterns. In the same time, the transportation main problems must be solved through elimination of the conflict points between

pedestrian and vehicle movements, integrating them instead through pedestrian pathways that are connected to public and private transportation points.

Abstract. *Urban design is a kind of process to meliorate environmental quality and it is trying to make desirable place for people. Considering that environmental factors are not measurable directly; so, finding the quality of dimensions, it is necessary to introduce this. Therefore, in this paper firstly, using descriptive-analytical approach and documentary studies, it will provide a framework for investigating of environmental quality with their dimensions. Then, regarding to the morphological aspect is the most tangible and enduring aspect to review other dimensions such as visual, social, temporal, functional and etc, has been paid to exploring the historic city Niasar (one of the historic city of Iran) with gathering data through using observations.*

Thus, recognizing and extracting the unique features of the city texture and applying knowledge of urban design, it will be presented some guidelines to improve the environmental quality and create better place for Residents.

Key Words: *Urban design Guideline, Environmental Quality, Morphology, Niasar*

Introduction

Today, Iran's cities with inefficient and non-responsive development to the needs of contemporary people from one hand and the loss of natural identity and Organic skeleton of the city on the other hand have been lots of problem, This issue has caused to make a fundamental change in its shape and form That does not have any consistency with traditional context. Niasar city with several thousand years old which is breathing in heart of the central desert not an exception as well and requires some exploration in its original concepts and features in addition to meet the quality requirements of modern city.

According to the urban designing purpose which is promoting environmental desirable qualities, "urban design guidelines", introduced as a proper tool to guide the development in these textures. Designing guideline is an accurate guidance document that determines the way on implementation of development program vastly according to the urban strategies of local authorities or other related organizations and most of the time attention to preserve the local distinctiveness" (CABE 2000); Therefore, it is necessary to take an appropriate approach to formulate. Hence, the current article is going to investigate the existing documents related to the issue and has been extracted the effective factors in urban morphology from commentator's point of view through the library based study by the assumption that one of the designer's techniques for identifying the unique characteristics of every city's texture is its morphological analysis to gain the proper pattern for morphological analysis of Niasar and in continue will identify the urban Insufficiency by field impressions and observations made in the city and finally take a small step to improve the of urban desirable quality with offering Urban Design Guidelines.

Urban Design; Meanings, Its Quality & opinions

Urban design is a relatively new term that during recent years has passed various approaches from birth to maturity. The evolution in provided definitions of urban design during last four decades shows that (Table 1) in earl of 20th century, theorists of this profession, considered more the aesthetic aspects and the area appearances of urban and usually, and frequently the processes leading to the production of urban areas were ignored.

Table 1. Some definitions of urban design (source: the authors)

Theorists	Definition of urban design
Gutheim 1963	Urban design is part of urban planning dealing with the aesthetics and determines the order and form of urban.
Lynch 1974	The main objective of urban design, to improve the quality of the physical environment of people and then people's quality of life through it
Michael Southworth 1989	Urban design is a tool for "environmental quality management". Although comprehensive plans and land use plans are an important part of urban planning but without a strong urban design, there is no guarantee that land use plan be able to maintain or improve environmental quality.
Calthorpe 1993	Urban design is something beyond mere aesthetics of the urban environment or artistic establishment of its elements. Urban design deals with creating and maintaining urban places in which the response to ecological issues, economic prosperity and social life are combined in an appropriate manner.
Jon Lang 1994	Urban design is a complicated art, since should simultaneously seek to achieve a set of goals, from providing shelter for activities to create a sense of place, technological enhancement of the built environment, health of financial and biological environment. Hence urban design as the art of creating relationships between elements of the set, is the concern for several professions

From the 70s of A.D onwards, theorists such as Jan Gehl (1971, pp.143-146), by adding the concept of activity to definitions of urban design introduced place as the common factor in all essential activities, community and voluntary. Gehl believed that most of activities other than necessary activities are accomplished only when an appropriate area is provided for them. Based on this view, quality of place plays an important role. This attitude has led to the emergence of a concept under the title of public realm in urban design: which brought place-making approach. This approach seeks to promote more the sustainability of public places with a certain identity, in accordance with the needs and desires of human and social activities in local communities, poses "Quality" as one of the core concepts of urban design. In other word, nowadays the ultimate goal of urban design is to improve environmental qualities, and what leads to achievement is comprehensive understanding of the qualities depend on good urban design which in most urban contexts have been analyzed (Table 2).

Since the quality design of a place, is inevitable about responding to various dimension of that place, it's possible to define the constructive components of quality parallel to the constructive Component of place. So by using the model of sustainable place (Golkar, 2000) that is derived from place model of Punter, Constructive components of urban designing qualities are set in three groups of Functional Experimental-aesthetic and environmental. Therefore, qualities associated with each contrastive components of place can be stated briefly according to the table 3-

Table 2. Good urban design qualities (source: the authors)

Connoisseurs	Qualities of good Urban Design
Lynch	Vitality - Meaning - Compliance - Access - Control
Bentley	Permeability - Variety - Legibility - Flexibility - Visual adaptability - Perceptual richness - Personalization - Energy - Ecosystem
Jacobs	Mixed use - Permeability - flexibility.
Appleyard	Life capability - identity - access to opportunities, imagination and enjoyment - Meaning and authenticity - Social and public life - inclusiveness
Tibbalds	Use and social mixing - human scale - Pedestrian-oriented - legibility - adaptability - visual pleasure
Trancik	Communication - restriction - Edge continuity - axis control - spatial Communication
CABE	Personality - cohesion - restriction - Ease of movement - legibility - adaptability - Variety

**Figure 1. Components of a place making (source: Golkar, 2000).****Table 3. Effective qualities in introduced components (source: the authors).**

Type of place components	Environmental qualities
Environmental component	Compatibility with nature
	Safety
	The environment cleanliness
	Energy Efficiency
Experimental – aesthetic component	Readability
	Visual proportions
	Sensory richness
	Identity and sense of place
Functional component	Belonging color
	Permeability
	Variety
	Inclusiveness
	Climatic comfort
	Safety
	Adaptability
	Flexibility

Principles of urban morphology, opinions and elements

Urban morphology includes variety of definitions such as urban design. For instance, MadaniPour introduce urban morphology as a systematic study of form, shape, map, structure and functions of artifact context of the cities, the origin and mode of evolution of these contexts over time; while according to Hillier, urban morphology is the study of social forms that have been developed in the physical layer of a city or conversely, on how the physical form produce or reproduce social forms (Hillier, 1985). In fact, although urban morphology is focused on the study of city as a physical environment, but also implicitly establishes a link between spatial and material elements of the city and social and economic forces which shapes it (Moudon, 2000). Understanding the Importance of urban morphology for city designers aid them to acquire knowledge and to recognize local patterns of development and the process of change (Carmona, 2003).

Although there are different approaches in relation to the study of urban form, but two main approaches can be introduced in the field of urban geography and architecture. Hence, in order to develop a comprehensive framework to study Niasar urban form, the ideas of theorists in the field of geography from the viewpoint of Conzen, Caniggia, Kropf are examined, and then we examine field of urban architecture from the perspective of Sitte and Moughtin, cullen, Colin Rowe, Transic and Lynch.

Conzen point of view

Morphology of the German school as an organized field in geography began to get formed, and developed by Conzen theories; he sought to explain the current structure of a city with its historical development, he expressed urban form in three aspects of city map, city context and land use (conzen, 1960). According to his view with the growth of the city, blocks and lands patterns, through building accumulation, setbacks of buildings and transformation of land parts pattern change adaptively and increasingly. Thus, he considers a morphologic period as a representation of a stage in city development that creates distinct forms with social-economical needs of society for cultural vision. From this perspective, he categorized morphologic areas into three groups of organic morphologic, morphology of interventions and morphologies in transition.

Caniggia point of view

Italian school of urban morphology which has founded since 1950 by Muratori, and continued by Caniggia with the aim of understanding the built form through the study of historical processes (Koster, 2001). According to him, a kind is recognized by specific morphologic combinations that rule internal organizing and its relations with structures and nearby spaces. In other words, type of usage has not any effect on kind and typology is determined in a specific scale by the features of elements belonged to smaller scale which exist in the same environment. Therefore, for each period of expansion of the city, there is a kind of base housing unit which represents culture, religion, law, technology and economic status of the time period (Mir Moqtadaei, 2006).

Karl Kropf point of view

Karl Kropf, made relation between the concept of Conzen urban morphology with city context of Italian school and expressed the concept of urban form in seven levels including 1-whole city 2-urban parts (blocks and streets) 3-pieces; 4-buildings; 5-rooms and spaces; 6-building's structure such as walls and roofs; 7-raw and construction materials. From this perspective, describing a context with all its details is meant to describe its components and how they are

organizing and the features are used to describe such components are: position, outline and its internal arrangement.

Sitte and Moughtin point of view

Sitte and Moughtin perspective in relation to the study of urban form is aesthetic. They believe in intuitive analysis method and the relationships based on the walking observer for the urban form (Collins, 1986). For this reason, Sitte have studied the characterization of the old cities of Europe Aesthetics emphasizing the importance of public green spaces, squares and streets in the form of a city (Tavalaee, 2000). For this reason, they study the squares by checking the relation between square with buildings and monuments, considering the openness of square, surrounded space, size and form of square and spatial relations of the squares; and consider the streets by analysis of proportionality between the length and width of the street, constituent structures of the body of the street, perspective and how to end street to Monuments. Also about green places he considers decorative plants in order to study the rate of creating pleasant and favorable contrast between artificial arts and freedom nature form (Tavalaee, 2000). Also Moughtin classified based on the ideas of Camillo sitte of streets, boulevards, squares and public parks with and the defining features of the in public domains, and also for analysis of urban aesthetics he listed their discipline, unity, harmony, balance, symmetry, scale, appropriateness, rhythm, contrast and harmony.

Cullen point of view

Cullen knows the possibility of surveying the form of a city through discovering the relations and arrangements of the elements. According to him, space in plan and section contains different senses; in fact, he believes urban landscape as an integral element of the study, and for this reason, he introduced three factors of optics (Serial vision), Place (the reaction of individual towards situations like near/far, here/there and ...) and Content (Color, context, type and ...). According to Gosling, Cullen's idea regarding to changing of the centrality of the histrionics into concentration on the common observer and his findings from environment, he added some words to design the concepts such as wall face, street face and floor face (Gosling, 1996). Pakzad considers Cullen, coherence, being trapped, identity, balance, unity, visibility, confidence, complexity, connectivity, proximity, memorabilia, openness, Adornment and incitement to explore as the features of favorable urban form (Pakzad, 2007). Bentley believes that Cullen considers the appropriateness of relative isolation by a subtle expression, and tries by designing of a visual structure to give clarity and character to the city. In a simple conclusion, according to Cullen view, the main function of city is social unity; Based on this, city should be open and accessible for public and this is possible only through linking significant and population attractive points, maintaining important element and attractive views, keeping hierarchy between old and new, public and private domain, by constructing family of buildings and places.

Colin Rowe point of view

Another key tool for analysis of city form is figure-ground diagram, which Cullen was one of its first fans (Zekavat and Farshad, 2011). In an urban environment, buildings form the shape and environment forms the ground. Urban areas come to eye when their surroundings were surrounded by joint or nearby buildings. If the distance between buildings become more the buildings will be departed; in this view, it is not possible to create a positive phase, and the relation between figure and ground disappears. To avoid such a thing, the buildings and areas should have equal value in urban studies and the quarrel between piles and areas or form-floor turn into cohesion, coexistence and complementarity in urban design (Zekavat and Farshad, 2011)

Roger Trancik point of view

Trancik perspective about the way of city investigation and its physical intervention comprises three Major theories:

1- Figure-ground theory that it related to two-dimensional Analysis of plan and consider six types of grid, angular, curvilinear, Curvilinear, Radial Concentric, Axial and organic for relation of Mass - Space in Traditional city.(Golkar, 2009)

2- Linkage theory that discuss about linking lines Connection Including sidewalks, open linear spaces and ...; and indicate 3 general form of compositional, mega, and group form for Spatial relationships of urban elements.

3- Place theory which is based on understanding of Cultural and human characteristics of physical space.

Lynch and Radwin point of view

Lynch assumes the Figure of the City as a text that must be able to read it or return the readability to it. He introduced six criteria of types and species the elements, quantity of elements, density, texture, central structures and overall distribution of space with Radwin in 1958 to collect and analysis of city form.

Proposed framework of the research

As it mentioned before, the main goal of urban planning is improving the environmental qualities through the constructive dimension of place. According to the issue these mentioned has been investigated in urban morphological studies with different excretion ,it can be claimed that, morphology as the most tangible and enduring aspects, provides the possibility of adopting coherent approach to identify the unique characteristics of environment and using them in creating better places for people.

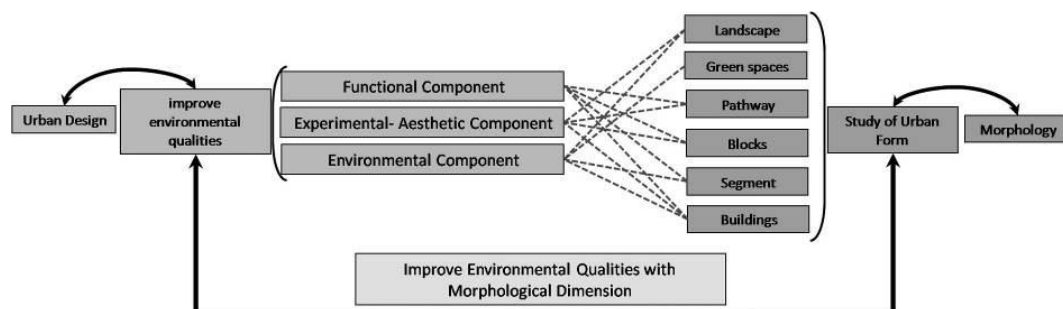

Figure 2. The relationship of urban morphology and urban planning (source: the authors).

So, this paper studies the city in three scales of macro, middle and micro by urban morphological technique in a way that is coming continue:

A: Macro scale

This level by investigation of urban background in three section of back ground, middle ground and fore ground has studied the Spatial arrangement and interactions of natural and artificial environments and tries to determine the mode of changing the morphologic areas in addition to the identifying the morphological areas by study of main structure and the way of urban development in different eras.

B: middle scale

In this level, studying super-blocks that are made by segmentation of city's body by main streets is taking to consideration. To this, after classification of super-blocks based on their shape, morphological areas and major applicability of their manufacture, the study about the way of super-block's connection, morphology of the most important remained public spaces and the amount of influences of each one.

In fact, this level of studies is sealing with finding responses to qualities like Legibility of environment (by examining the basic structure of the city and placement of key elements), permeability and security through the exploration of the super-blocks, the number of domestic routes), Variety (distribution of land uses), local identity and harmony with nature (through checking the super block shapes and how they interact with their natural substrate).

C: Micro scale

This step of studies is dealing with block's morphology in their pathways, pattern's parts and location of establishment. So, by the studying, the way of combination of mass and space in each urban block, Shape of the Surrounding passages, Pattern of each block's constructive parts, trend of change and the extent of its comp ability with the place of establishment, passages and open space, safety of environment will be investigated; and in the next steps, by evaluating the block's dimension, existence of visual indicators or activities or variety of uses on that, qualities such permeability, legibility and Variety will be study. In a step, by evaluating the place of establishment in pieces and used materials in construction's pattern and qualities like climate comfortably, local identity and ecological compatibility will be study.

Morphological study of Niasar

According to what brought in previous, the morphological study of Niasar has been done in three parts. But from the limitation of writing on one hand, and because of the paper's emphasize on improving the public arena's quality on the other hand, two Scales of macro and middle will be analyzed in this part.

Macro-scale

Niasar is located in Isfahan Province and The western part of Kashan and has been formed completely affected by natural substrate.

As is evident in the pictures below it can be say that the physics of this city is ended to mountain and from the other direction is ended to gardens and Plains.

Therefore, the main structure of the city can be divided into two natural and artificial parts in which Mountains, gardens, waterfalls and surrounded greenery spaces, the main elements of natural structure, and two north-south streets of Valiasr and Montazeri, 10 Existing districts with Chaleqab tower, the holy area of Chartaghi, Safaviyeh Kooshk, and collection of halls form the main elements of artificial structure of city.

Evaluating the map of historical evolution of the city shows that, it started to shape into two waterfalls as Confluence of natural and man-made environment in North-South slope. So, many religious signs and symbols constructed on the top of the waterfall and dominant morphological is organic. Gradually, by new developments and expansion of the city morphology of intervention have emerged and change the form of the development of the city from central to linear form. The southern and north-eastern part of the city in new areas transitional morphology has begun to appear. This significant cause uneven distribution of mass

construction and gradually will take out the shape of the city from the visual and functional balance.

Figure 4. Geographical location of Niasar.

Location of strategic view

Figure 5. The investigation of urban ground in macro-scale (source: the authors).

Figure 6. The main structure of the city, mixing nature and man-made (source: the authors).

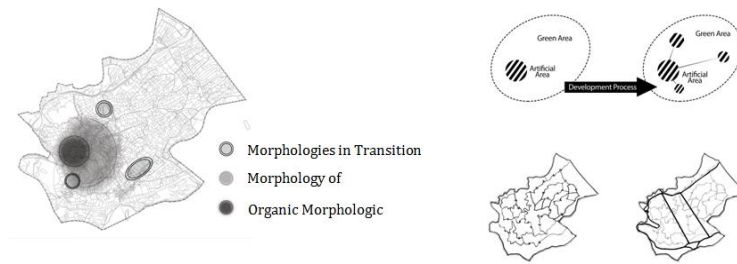

Figure 7. Form of urban development

Figure 8. Accumulations of urban indicators in heights (source: the authors).

The middle scale

As mentioned earlier, the main elements which are analyzed in this section include:

- Urban super-blocks that are made by main pathways and old pathways of city as well (discriminant gardens of green area that change their essence to the main streets in development process.
- Squares and Nodes that have been created in interaction with main streets

As it's shown in following maps, the structure of main pathways of Niasar has been made by a three parallel streets, that their morphology is different from pattern of organic pathways within super-blocks. Mentioned passageways divided city to main super-block that characteristic of each of them has been given in following table separately.

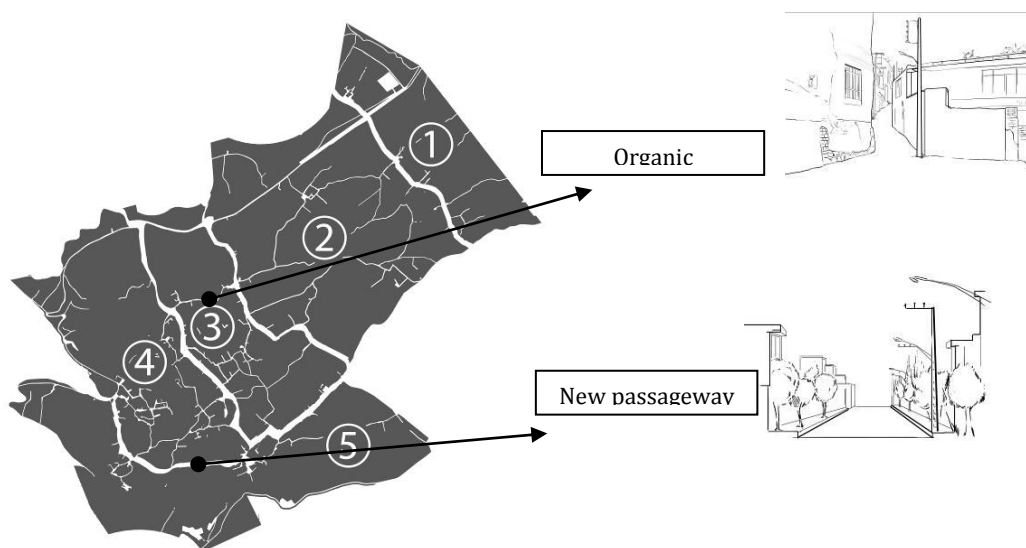

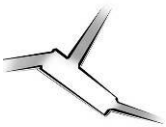

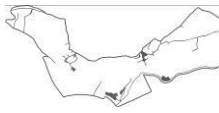

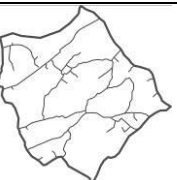

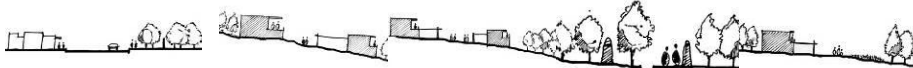

Figure 9. Formation of super-blocks and Morphology of their pathways (source: the authors).

Table 4. Investigating the morphological of super-block and their qualities (source: the authors)

		Block number				
		5	4	3	2	1
Super block form		Geometric regular	Geometric Irregular	Geometric regular	Geometric regular	Geometric regular
Blocks form		Irregular	Irregular	Irregular	Irregular	Regular
Number of Block		6	10	12	11	5
Super block dimension (meter)		450*2400	800*1700	500*1000	1270*1460	460*1460
Dominant uses		Agriculture residential	Commercial – residential	Agriculture	Agriculture	Agriculture
Figure and ground diagram for each Super-block						
Morphology of most of the squares						
Pathways' Morphology		Curvilinear	Organic	Organic	Curvilinear	Axial
						
Level of responses the environmental qualities						
	legibility	average	Good	Good	Weak	Weak
	Permeability	Weak	Good	Good	Weak	Weak
	Functional Variety	average	Good	Good	Weak	Weak
	Intuitive richness	Weak	Good	Good	average	average
	Compatibility with nature	Weak	average	average	average	average
	Safety	Weak	Good	Good	Weak	average

Conclusions & providing urban design guidelines

According to what has been mentioned above, with change in the form of super blocks during development of Niasar city, and consequently with change in the quantity and form of blocks and their internal routs, their environmental qualities have been changed. Therefore, to analyze the form of the city based on the provided model, it is proposed that future developments to promote environmental qualities should be implemented based on the compatible forms and ground. So, morphologic oriented urban design guidelines should be done with respect to the following table.

At the end, in order to get sustainable place through increase in the environmental qualities, all of the urban dimensions should be analyzed; and Morphology as the main aspect in sustainable analysis is the beginning of this process.

Table 5. Providing morphological Urban Design Guidelines for Niasar (source: the authors)

Scale	Purpose	Objectives	Guidelines	Morphological Factors	Qualities
Macro Scale	Sustainability based on the preservation of urban historical and natural character	- Preservation of natural features and strengthening their impact on the physical structure of the city - To regulate the spatial structure	Using natural slope of the ground for surface water's disposal.	Slope direction & Topography	Natural harmony
			Shaping blocks according to micro-climate, wind, and Penetration level of sun and ground's feature.	Ground	Natural harmony
			Use of local and ecological materials resistant to rainfall and radiation	Environmental friendly	Natural harmony
			Avoiding checkered segmentation, attention to ground's pattern and existing natural complications	Main Structure	City character and Identity
			New construction should be guided in ways that prevents the creation of formless spaces, incomprehensible, without specific form and edges in remaining space,	Figure and ground diagram	Sense of Place
			Maintaining and strengthening memorable agents such as paths, buildings, squares	Main Structure	Identity
			Avoid excessive physical development of urban green zones	Ground	City character Natural harmony

Middle Scale	Continuing of vitality and social life		Creating cultural – athletic center in functional section of the city and neighbors	Functional dominance and distribution	Variety and Safety and legibility
			In new developments must be avoided to creating the deadlock that makes the Communication systems introverted	Figure ground diagram and	Safety and permeability
		- Increase the participating and encouraging the pedestrian-oriented texture.	Create various blocks into the internal development in order to create different types of buildings and their uses	Classification of block in term of shape the major of manufacture	Variety and legibility
			Prediction of pause spaces ,and gathering for promoting social interactions	Morphology of main square, nodes and pathways	Safety and Variety
		- Conversion of the main backbone of the neighborhoods to the space of services appropriate with local needs.	Considering the form of spaces to create enclosure, with clear and defined edges that are imaginable.	Figure ground diagram and	Legibility
			Predicting active uses at night	Functional dominance and distribution	Safety and Variety
			Strengthening the relationship between the center's activities.	Functional dominance and distribution	Safety and legibility
			Predicting spaces with mixed uses.	Functional dominance and distribution	Variety and legibility
		- Enhance the safety, security and	Removing the far nooks and corners	Figure ground diagram and	Safety
		Life quality improvement			

discipline in public field.	Considering hierarchy of the public to personal arena because of their importance in creating safety and security and increasing individuals participation in community	Morphology of main square, nodes and pathways	Safety
- promote Legibility of the environment to improve the sense of place and vitality in	Applying indirect and organic forms in semi-privates paths accordance with the characteristics of the ground causing limited entering the strangers into the places	Morphology of main square, nodes and pathways	Intuitive richness
	That better mass using in edge of entries be in a manner that contributes to caret the gateway patterns and makes privacy for semi-private arenas with special identity	Figure and ground diagram	Safety and legibility
	establishment of physical Signs and strengthening existing signs	Functional dominance and distribution	legibility
	Maintaining and improving the strategic vision of public aspects to existing signs in texture.	Morphology pathways and Figure and ground diagram	Legibility and permeability
	establishment of physical indicators in twisting place of texture's organic passes and introducing the movement's direction and vision expansion in them	Morphology of main square, nodes and pathways	Legibility
	The combination of occupied and empty spaces done in a way that can create the spatial sequence and enclosure	Figure and ground diagram	Variety and Legibility

Urban morphology of historic fabrics and contemporary architectural design

Giuseppe Strappa

Dipartimento di Architettura e Progetto, Laboratorio di lettura e progetto dell'architettura, 'Sapienza', Università di Roma. E-mail: gstrappa@yahoo.com

Abstract. *The problem of the revitalization of small historical centers in the Lazio region is highly topical and requires urgent interventions. These new centers are undergoing a rapid transformation due to the change of functions in buildings and to a new social composition of the population. We should read carefully their urban fabric and built structures to actively protect their historical heritage and to design the indispensable architectural transformation. We need a method to read and design historical fabric transformation, ensuring across time transformations "congruent" with their formative process, also accepting the incontrovertible fact that an urban organism, like any living organism, is subject to continuous modifications. In Lazio these changes have, within certain limits, common characters in different centers that allow an intervention method for some aspects generalizable. Action is needed to update the existing built landscape in order to continue it in a historically coherent form. The proposed paper deals with the study and application of a method of reading and designing the historical built landscape based on the notions of urban organism and on the typological process applied to the historical centers of small towns in Lazio.*

Key Words: urban-morphology, architecture, urban-design, historical fabric

My intention is to propose some considerations about a method of reading and designing architecture developed by Roman School of Architecture and the way we are trying to update this method in designing interventions for the revitalization of small historical centers in the Lazio region, a highly topical problem which requires urgent interventions based on scientific methods of analysis and design.

First of all I will propose a synthesis of the theoretical principles, then I will present some examples of application of the method to architectural design in the Lazio region, conducted with Alessandro Camiz and Paolo Carlotti, considering, in particular, some exemplary case studies as Pisoniano, Bellegra, San Vito Romano.

The method of design used in the research is based on the principles developed by Gianfranco Caniggia, but belong, in general, to the architectural tradition of studies on the architectural organism began in the School of Architecture of Rome, between the two wars and continued after the war by Saverio Muratori.

The work of Gianfranco Caniggia, as a scholar and architect, must in fact be studied inside the general background of continuity with his own cultural area, whose heritage was driven by Saverio Muratori, who has had a fundamental role in the formation of Caniggia's thinking.

I will try to develop some reflections about Roman School heritage starting from didactic experiments conducted between the two wars, based on history's new centrality in built environment interpretation and on the architectural "redesign" as a tool to transmit the notion of organism intended as an "integrated, self-sufficient correlation of complementary elements expressing a unitary aim".²⁸⁸

This didactic system was boosted by *Monumental Restoration* teaching, imparted by Sebastiano Locati during the first year of the *Regia Scuola di Architettura* in via Ripetta in 1920-21, before it became a university faculty.

²⁸⁸ G.Caniggia, G.L.Maffei, *Composizione architettonica e tipologia edilizia 1. Lettura dell'edilizia di base*, Venice 1979, page 47.

This teacher played a significant role in linking up roman didactic with Lombard research of Camillo Boito. Trained at the Brera Academy and then at the Milan Polytechnic School and an authority on Roman monuments, Locati proposed restoration based on rules analogically derived from a stylistic comparison between synchronic works.

Restoration was considered as the synthesis of all architectural disciplines.

For that reason, restoration was not just intended as study and preservation of the document's historic and artistic aspects but also as simply a design operation which, like all design, is a critical modification of the built environment.

This teaching was then taken over, in the new Roman School of Architecture, by the dean Gustavo Giovannoni for twenty years, testifying the discipline's founding role in the Roman school's more general didactic design context.

For Giovannoni, teaching restoration of the work's original organicity by reading typical transformations, was actually a tool towards comprehending the forming processes of architectural organisms and architectural design.

In fact, this teaching was imparted not only through institutional courses on *History of Architecture* but also through a real "didactic organism" inevitably joint with courses such as *Stylistic and Structural characters of Monuments*, imparted for many years by Guglielmo De Angelis D'Ossat as from 1937, in the conviction that restoration possesses a critical and, all round, design matter.

Much has been written during the post-war period about the conservative positions of this School, generally considered "academic" in its meaning of pedantic submission to traditional design rules.

In fact professors as Gustavo Giovannoni, Vincenzo Fasolo, Arnaldo Foschini and Giovan Battista Milani (professor at the Engineer School of Rome University) were perfectly conscious of the recent conditions induced by modernity. Yet, as all classic thinker, they interpreted modernity as a loss of rules and fragmentation of the basic unity of knowledge.

They were fully aware of the true conditions of the modern crisis and, also, how it was impossible to repeat the archaic unity of things that had enabled building cycles, decadence and regeneration of forms.

They also knew that the world required new answers to new, complex problems.

Yet they did not agree, and this is where they differ from the Modern Movement's pioneers and their followers, on the faithful adaptation to new myths and on the irreversibility in the loss of every shared and authentic language.

They do not interpreted the built environment as it appears but, according to their own design ethics, making interpretation converge with a transformation hypothesis.

Giovannoni's intuitions, Muratori's major territorial visions and Caniggia's reading of the organic transformation of urban fabric are *interpretation that not only imply design but are, themselves, design*.

Totally perceiving how contemporary architecture cannot be condensed in a single corpus of design theories, Giovannoni (as far back as the Thirties) sustained the existence of numerous, contradictory forms of modernity.

He posed the question of the arising conflict between analytical-technical and intuitive-artistic components in architectural design and in its consequences: the contradictory relationship between structural systems, construction and architectural form.

Giovannoni blamed the split between architectural "imagination" and "construction" as the very origin of the dissolution of the "principle of truth" that has always been, during the course of history, one of the ethical rules that architects were called to obey.

Giovannoni did not reduce the "principle of truth" to a simple cause-effect relationship between structural solutions and spatial pattern.

In fact, he individuated the dividing of the original design unity into various, specialized aspects of modern architectural thought.

A "positivist" line of thinking, a second set of theories actually linked more to physiology than to reason, a third group of theories based on the modern expressionist interpretation of

architecture, derived from studies on the use of psychology in interpreting artistic work, as in Wölfflin, a fourth group of theories of those who derived directly architectural forms from the environment, simplified in the internationalism-localism combination.

Giovannoni condemned all those trends as the lack of a general shared order that could freed design from the volatility of fashions and from extemporary invention.

Anyway, at the same time, Giovannoni admitted how the Modern Movement theoretical innovations, although with unexpected results, were at least an attempt to overcome the late 19th century eclectic drift.

Contrary to a superficial historiography that separated academics from innovators, Giovannoni's critics to modernity was perfectly updated and fruitful, consciously integrated in the contemporary debate.

Starting from his initial studies during the forties, Saverio Muratori's thinking seems to extensively resume and develop certain issues raised by Giovannoni, by basically including modernism among eclecticismisms that had lost the order governing the unitary formation of architectural organisms.

In his *Storia e critica dell'architettura contemporanea* (1944) Muratori also reconsider, more generally, the linguistic fragmentation that preceded the first world war as the origin of the crisis in modern language.

This phase was an ambiguous passage in the history of architecture; disbelieving linguistic unity, it ended up by being an "anti-stylistic" period".

Gianfranco Caniggia, disciple of Muratori, also accepted the basic historic need for the Modern Movement. The Modern Movement was however mainly accused of not having considered the real *forming processes* and, therefore, of professing aestheticism and being individualistic.

Caniggia developed, innovated and systematized Muratori's heritage by introducing the issue of not only comprehending monument's language but also basic building (the "dialect" of simple houses) to such an extent that he almost founded a new discipline.

The method of redesigning architectural process proposed at Caniggia's courses (in Genoa, Florence and Rome) inherited, updated and upgraded the built landscape.

It was a way: i) to read buildings and fabrics; ii) to understand their forming processes; iii) to continue them through the project.

Therefore *the architectural design is the continuation of a never ending process*.

Developed through fundamental experiments conducted at courses held by Muratori in Rome as from the 1961-62 academic year on redesign of historic fabrics such as Tor di Nona but also on contemporary fabrics like Centocelle, the experiments proposed by Caniggia tended to approach, through successive approximations, the real built environment process through interpretation.

This interpretation that gave rise to a design method which, directly derived from the built environment, avoided the shortcomings and risks of the ideology that largely contributed to the disaster of so many modern architectural experiences.

Affinities with Aldo Rossi and Carlo Aymonimo methods aside, also in the light of subsequent studies, Caniggia's research on the formation of fabrics and their transformations must be acknowledged as being surprisingly original in Italian schools of architecture.

These brief considerations will perhaps help to explain how according to Caniggia the multiple built-environment forms could not simply be classified and scientifically processed as in the series of typological studies generated by Giulio Carlo Argan's analysis.

According to pre-modern principles, Caniggia sensed how it was necessary to extract hidden, deeper meanings from urban fabric: the architecture of the cities, houses as monuments, thus became not just simple constructions but *textes* and architects had to be capable of interpreting the message transmitted by them, in this way understanding not only what the built environment *appeared* but, above all, how it *should* be in the future.

For many years I have been involved in the continuation of this method of study, which I have tried to update through researches carried out in the Polytechnic University of Bari and the

University "Sapienza" of Rome. In particular, research on minor historical centers in the area west of Rome, conducted with funding from the Ministry of Scientific Research and now in course of publication, gave, in my opinion, good results.

This research adheres to a broader national research, sharing its assumptions and considering specific connotations of Italian landscapes as suggestion for tools, different from current ones, for architectural design in Italy, and outlines a possibility for its original connotation. In particular, the research, conducted in our Lpa (Reading and Design of Architecture) laboratory in "Sapienza" University, focuses on specific characters of territory of the Lazio region, given by the diffusion of the small towns, of high historical value, which are rapidly losing their landscape and settlement qualities. These minor centres are furthermore structurally weakened by the proximity of the Roman metropolitan area.

The research concerns the following issues: i) local historical paths and courses and their recent transformations, given as elements structuring the form of the territory; ii) small and largely built "nuclei", commonly known as "minor centers"; iii) the urban sprawl formed in the last two decades.

The research aims to develop a method to understand the historical "small towns" of Lazio, updating the typological and processual method, based on the application of scientific criteria for specific reading of urban tissues, analyzing at different scales the links between the characters of anthropized territory. These links are particularly evident in a highly plastic-masonry (and therefore organic) region such as Lazio and constitutes, on one side the specific cultural heritage conservation work to be done to protect settlements and built landscape and, on the other side, possible tools to be deployed for the design of "mending" and also in new interventions. In this sense, the meaning of the word "landscape" that will be used, as mentioned, differs from that, however settled in literature, and derived from the picturesque tradition of landscape architecture, meaning by "landscape" the readable signs of the territorial anthropization process, considered in their indicative and testimonial value.

This method will be used not only for the protection of minor historical "minor centers" identifying which characters of the tissues are essential to protect the cultural heritage, but also to program transformations compatible with the morphogenetic process of historical buildings and to develop tools to cope with rapid and consistent reconstruction of tissues that may have been destroyed by a condition of long abandon or by improper use.

The studies over time have shown that common evolution of the urban fabric in this territory originates from a dequantification of the domus type (and other types of courtyard houses) which gave rise mainly to the extensive phenomenon of the formation of the "pseudoschiere", singlefamily and single-faced housing units, also found however as a formative unit in the tissues of a large number of Italian towns (see the surveys carried out in the areas around Genova, Venice, Rome, and in Puglia, some of which are reported in literature).

Next to the formative unit, differentiation, articulation and diversity of results, identify (make individual, unique and unrepeatable the character of the town) the concept of courthouse, constitutes one of the greatest treasures of the fertile countryside of Lazio and the premise for its typological and constructive renewal.

For this reason the investigation, taking also into account its proposed operational purposes, started by considering the housing organism as a result of a sequence of construction acts that ends with the formation of an urban organism in the territory and begins with built elements (minimal component critically selected for subsequent aggregation), passing through successive scalar degrees: the structures of elements, in turn, systems of structures (set of structures that contribute to the same aim and are not independent), the whole constructive organism (with relatively autonomous systems that compete for the same purpose), aggregated organism.

The research makes some proposals for different structures and systems and their organic relationships within the building, and becomes a problematic node specific of different cultural areas, suggesting to organize the research on themes aggregated not only around the more general meanings of the specific term organism, but also investigating those structures and systems that are particularly significant for individual cultural areas.

It also appears clear that the results of this research, in the way shown above, is willing to overcome the current method, in the end still late romantic, based on data reading of the design problem (the territory at different scales) according to an individual and literary manner (e.g. the endless publications on the topic of "fragmentation" of the territory).

Under the current total loss of the concept of process, the interpretation of the neo picturesque built town usually suggests the idea of randomness, of unique structures that have assumed the present form "worthy of being painted", in fact (e.g. the tradition of painted landscapes of Latium, from Tivoli to Anticoli Corrado) but that could take on countless other forms. This fact certainly contains some truth but completely useless, however, for the project. Ignoring that part of truth essential to understand and design the newly found rule for the formation and transformation of the built environment, a rule that can let us appreciate, through its endless exceptions, also the richness of the life of urban tissues and buildings.

Believing that the characters of the Lazio region (only partially affected) should be destroyed only for whom that doesn't want to acknowledge them, the research has produced some tools related to the concreteness of the transformations of the built landscape, by a progressive reading the formative process as a basis to understand which are the congruent and possible developments, to finally define which are the possible tools for redesign.

The representation of the structure of the territory, identified through the stages of its anthropic use, can only start by reading the routes which, as any given built reality, have their typical characters, i.e. are recognizable in their form and evolve with common characters that can identify historically their phase, and locally their relevance to the natural characteristics of the soil to which they are associated.

A first guidance distinction between typical paths can be implemented through the hierarchy of tasks performed: spatial paths originally generated by migration and, subsequently, the links between cultural areas of great polarization (examples are contemporary highway routes); local paths, internal to each region or between the border areas, polarized by the settlements and urban areas; land routes, links to the scale of production areas; urban routes, routes within urban areas.

These pathways are structured, in turn, hierarchies that establish organic relationships in the territory that can be read by mapping them.

Scale of urban organism in relation to the territory

Study of the formation process of the settlement, from the existing routes to the buildings related to the area.

Documentation

Cadastral maps of existing land and buildings prepared by Technical Revenue scales in 1 / 1000 and 1 / 2000;

Cadastral maps or historical antecedents found in the 'UTE, State Archives, or other municipal archives;

Cadastral monastic property or family;

Survey from 1:5,000 aerial views to 1 / 1000.

Development

Chart of the mosaic of the urban cadastral land and areas immediately adjacent to the 1:5,000 scale obtained by plotting on the same scale and composing maps. This paper will include the relationship between territorial and urban roads and relations between inhabited and relevant productive settlement;

Map produced on glossy paper redesigning supplemented by previous contours. This map will place the urban organism in the geomorphological situation that has conditioned its transformations;

Map made with the same maps where you get the signs of construction and agricultural boundaries, paths, outdoor and indoor urban body and their relationship with the topography and hydrography . This map will study the hierarchical relationships between pathways and their significance in relation to the territory;

Charter of the mutations of the structure of the urban organism obtained by comparing the maps with the oldest of the historic cadasters.

Reading

Relationship between paths. Comparison between the different maps, from which it is obtained;

The formation and transformation pathways and tissues;

Formation of city walls, the continuity between internal and external routes, the routes and timing of tissues;

Relationship to productive areas;

Identification of land links and courses, adduction to funds;

Identification of territorial planned systems (centuriations. convent subdivisions etc.);

Check recent urban expansion (suburbs) in relation to tissue existing land obtained by comparing the different maps;

Reading of the change of role in the system of scattered buildings: i) outbuildings used for agricultural uses(farms, cottages, farms, etc.); ii) specialized antinodal facilities urban or suburban (convents, hospices for pilgrims, post stations, shrines, churches and rural); iii) specialized structures for production (factories, tinali, mills, plants etc.).

Scale of the urban organism (formative phases)

Hierarchy of routes and the formation of tissues as a result of the training process of the urban organism. Nodality and antinodality for pathways and tissues.

Documentation

Current cadastral maps of the urban scale in 1/1000 and the urban core and the relevant territory in the scale 1/2000 (same maps);

Cadastral maps and historical background (same maps);

Photogrammetric aerial survey maps and aerial zenithal photos in scales 1/2000, 1/1000, 1/500;

Archaeological maps;

Geological maps;

Publications of local history, guides, archival records etc.

Development

Base Map: Urban cadastral Mosaic scale 1 / 1000 and 1 / 2000;

Comparison, based on maps, including cadastre and land registers current history;

Charter purified from recent structures, at the stage before the nineteenth century expansion (i.e. expansion during Murat rule) and traumatic changes made in the historical fabric from the end of the last century;

Map overlay to natural manmade structures, useful to understand the differences across profiles, gradients, hopping height, terraces that have affected the formative stages of the urban organism;

Chronotaxis: Historical, chronological order, relating (directly or indirectly) the formative stages of the urban organism. Should be reported in order: Year, News, Source, grade reliability.

Reading

Finding ways of warping the urban fabric (indicate graphically different lines of different orientation);

Identifying the relevant sections for each course;

Identification of central and peripheral urban polarity (bridges, ports, intersection of routes etc.).

Identifying specialized nodal and antinodal buildings (churches, convents, palaces, cemeteries, markets etc.).

Identification of routes touching the polarity, often of greater length and continuity (Routes matrix);

Identification of new polarity and its paths of restructuring;

Identifying the paths between hierarchies (axes accentranti, dividends, axes controradiali)

Reading formative process .Each stage of the phases shall be identified by a map. Each map must reconstruct graphically: i) the urban core, as achieved in that particular stage; ii) adduction of the route; iii) Land outside the fabric; iv) polarity.

The research results are currently in course of publication with Italian and English tex: G.Strappa, A. Camiz, P. Carlotti, *Morfologia urbana e tessuti storici. Il progetto contemporaneo dei centri minori del Lazio. Urban morphology and historical fabrics. Contemporary design of the small towns in Lazio region*, Gangemi editore, Roma.

Typomorphological methods in planning practice; a case study of the *Plan d'Occupation des Sols* for St Gervais Les Bains (Haute Savoie, France)

Laurence Pattacini¹, Ivor Samuels²

¹ University of Sheffield. ² Urban Morphology Research Group, School of Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham B15 2TT, UK. E-mail: L.pattacini@sheffield.ac.uk, ivor.samuels@gmail.com.

Abstract. *The study draws from previous research and publications related to the use of typological and morphological methodologies to prepare and produce local land use plans (Plan d'Occupation des Sols, POS) for local authorities in France (Samuels, 1993; Samuels and Pattacini, 1997; Samuels, 1999; Pattacini, 2001). The focus is on the evaluation of the practical application of the plan for Saint Gervais Les Bains in the past ten years and the resulting built environment. Saint Gervais Les Bains is a market town and tourist resort in the Val Montjoie, below the Mont Blanc massif in the French Alps. Following the adoption of the 'Loi de Montagne' in 1985, two land use plans (POS), which had zoned much of the land in Saint Gervais as constructable, were declared nul and void. A new plan was then commissioned from Qualipos, a multidisciplinary team of consultants in 1997. The main aim of the new local plan, ratified in 2001 was to identify specific characteristics and qualities of the local environment in order to devise rules and design guidance to generate new developments better integrated in the existing landscape and the traditional built environment. Similarly to the evaluation work undertaken for another French local plan in Asnières-sur-Oise using the same typomorphological approach (Samuels and Pattacini, 1997), the study analyses some of the major projects implemented since the adoption of the POS and evaluate the extent to which the planning policies have influenced the form of these developments. Interviews with the relevant stakeholders and principle actors provide evidence to evaluate the effectiveness and limitations of the local plan since its adoption more than ten years ago. The aim is to identify how the morphological content of the local plan has influenced the planning and design process and how it has contributed to develop the specific local character of this alpine town. Fieldwork is scheduled to take place during February 2014 and it is intended to have the research completed in time to be presented at the ISUF conference in Porto in July 2014.*

Key Words: typology, morphology, planning practice, local character, evaluation.

Introduction

This study of the *Plan d'Occupation des Sols*(POS)for St Gervais Les Bains is one of four supported by the International Seminar on Urban Form (ISUF)which evaluate the application of urban morphologically derived methods in practice. It follows one of the recommendations of the ISUF Task Force (Samuels, 2013) and draws from previous research and publications related to the use of these methods in this type of local plan which was legally established in France in 1967 and replaced in 2001 by the *Plan Locale d'Urbanisme* (PLU). In particular, work undertaken by one of the authors (Pattacini, 1996) evaluated several cases including the earlier POS for Asnières sur Oise prepared by members of the same team and which used a similar approach to this plan. A number of publications have explored aspects of the experience of St Gervais and other cases using a similar approach (Samuels 1993, Samuels and Pattacini 1997, Samuels 1999, Pattacini 2001). Both the authors contributed to the typomorphological analysis which formed the basis of the survey (*rapport de présentation*) of the St Gervais POS, while the regulations (*règlement*) were mainly prepared by a legal team of the Paris based consultant, Qualipos.

Following a short discussion of the physical, social, political and economic contexts of the commune as they impact on the built form of development, an analysis is undertaken of some of the projects implemented since the adoption of the POS. A limited number of major actors were interviewed and an attempt has been made to evaluate the extent to which the typomorphological character of the adopted planning policies has influenced the form of these developments. Finally, some lessons are drawn from this experience which may be of relevance to other contexts.

St Gervais les Bains; a special place

The market town and tourist resort of St Gervais lies in the Val Montjoie, in the French Alps. The communal boundary includes the peak of Mont Blanc which it shares with the French commune of Chamonix and the Italian commune of Courmayeur (figure 1). With an area of 8768 hectares it climbs from the Faucigny Valley at 500m to the peak of Mont Blanc at 4807m. No other commune in France includes such dramatic changes of level. This produces an exceptional range of landscapes; from the permanent snow and glaciers, woods and forests at the higher levels to the agricultural land- pastures, orchards and small vegetable gardens, at the lower levels (figure 2). Traditionally the population lived in buildings constructed from local materials and adapted to the climate and topography. However, the agriculture could only support a limited population and there was a tradition of migration to neighbouring countries. The most significant architectural monuments of the region, the Baroque Chapels, were funded by these expatriates.

Figure 1. Location of St Gervais les Bains.

The advent of the railway and tourism disrupted this pattern of life and although some agriculture still exists it is economically insignificant (Olivier 1993). A new type of architecture was introduced at the end of the nineteenth century as large hotels were introduced to accommodate the visitors in search of cures in the Thermal Spa. They were in a style known locally as "*thermal*". The last half of the twentieth century witnessed the growth of mountain sports, again with the introduction of a new style of architecture - modernism. The small permanent population of 5,800 now rises to more than 20,000 during the four month winter and two month summer seasons.

Figure 2. The commune of St Gervais les Bains includes a wide range of landscapes.

Since Roman times the Val Montjoie has played an important role as a commercial route through the Alps. The historic core of St Gervais, the administrative, commercial and religious centre of the valley is located on the middle slopes at 800meters at a strategically important crossing point of the ravine of the Bonnant Torrent. Two fortified farms (*chateaux de la Comtesse* and *de Hautetour*) testify to a historically important defensive function. A third of the commune population is concentrated in this centre, which has expanded since the construction of a cable car lift to the skiing slopes at Le Bettex and above. All the main public facilities, library, Town Hall, schools are also located there together with some recent social housing. (figure 3).

Figure 3. The Bourg of St Gervais - the main settlement.

The other urban centre is the settlement of Le Fayet. It developed in the Faucigny Valley during the early twentieth century around the Railway Station and the Thermal Spa (*les Bains*). Small industries and most of the social housing of the commune are located there. It also accommodates the terminus of the Mont Blanc Tramway (figure 4).

Figure 4. Le Fayet. Main street, railway station , Thermal Spa.

Smaller settlements locally known as *hameaux* such as Bionassay, St Nicolas de Verece and Cupelin are located at strategic points on the ancient routes over the Col du Bonhomme. Originally small but dense groups of farms around a chapel these *hameaux* have been expanded more recently with private chalets (figure 5).

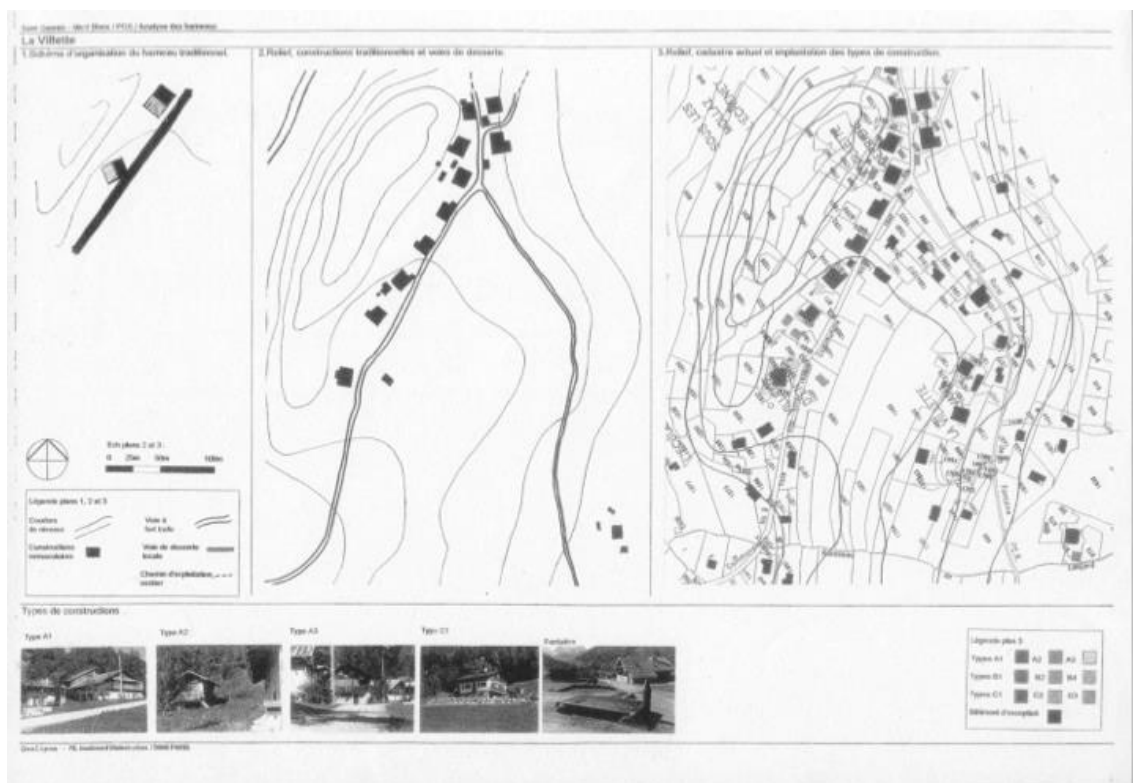

Figure 5. Typomorphological analysis of one of the farm groupings (hameaux) in the commune.

The territory covered by the commune of St Gervais les Bains has never formed a homogeneous entity and has always consisted of settlements of various sizes dispersed in the landscape. This dispersal has always made the mapping of ownership complex and resulted in the intricate mosaic of land uses found today. (Buston, Duprest and Duhamel, 1994, p.24).The

differences between the various types of inhabitants, dwellings and social Status: permanent or seasonal, urban or rural, old and new also create some tensions in relation to urban development and planning control.

From thermal spa to ski resort

Following the democratisation and development of winter sports in the last half of the twentieth century, the region around Mont Blanc has become one of the most sought after areas for tourism in the North Alps (Oliver, 1993). The mountains have become the playground of urban dwellers seeking sun and fresh air and the lost rural life (Gumuchan, 1989). In St Gervais 79% of the dwellings were built after 1948.

The approach to the planning of ski resorts in the 1970s and 1980s did not take into account the existing character of the sites. Such iconic resorts as Flaine designed by Marcel Breuer deliberately rejected local types and forms in favour of a modern architectural style (Pagand, 1996). St Gervais suffered from this period of euphoric development with a number of buildings ignoring the traditional relationships of built form and topography and the characteristics of landscape. (figure 6). These impacts on the landscape were exacerbated by the need to accommodate motorcars with access roads to the facilities and extensive car parking spaces which were used, at best, for only half a year.

Figure 6. Modern buildings at Flaine and St Gervais.

St Gervais with its established tradition of thermal and medical activities did not benefit as much economically from winter tourism as its higher altitude neighbours, Chamonix and Megève. One of the objectives of the commune over the last twenty years has been to restore its reputation and capture a greater number of the tourists descending on the region. One of the strategies for this is to reassert the attractiveness of the place by reference to the characteristics of the vernacular buildings, its reputation as a thermal spa and the quality and diversity of its landscapes. With ‘the implicit understanding of appropriateness’ (Habracken, 1998, p.229) having been ignored in the new developments linked to the tourism industry, it became necessary to apply explicit rules to maintain a balance between economic growth and the qualities of place.

The planning context

French planning operates within a legal framework based on written law and thus has much less

discretion to operate than the English case based legal system (Kropf, 2011). Thus any written document such as the POS which was introduced in 1967 and replaced by the PLU in 2000 (which included issues related to the sustainability agenda) is potentially a very powerful instrument for determining the form of places. The decentralisation law adopted in 1982 was a turning point in the French planning system with all 36,000 communes having the right to prepare their own POS (Prevost, Molines et al, 2012). Given that many communes are very small, with populations of one or two hundred, some of these plans inevitably are standardised since the cost of developing a plan tailored to local circumstances could not be afforded. For the same reason the administration of plans for smaller communes is undertaken by staff of the *Direction Départementale d'Équipement* (DDE) based at the main town of the Department who sometimes have a limited knowledge of the local context.

The standard plans specify broad land use zones on which are imposed quantitative controls in the form of maximum floor space indices. Local character is not necessarily considered as a justification for the rules and the specificities of the local area are often ignored. This was the case for the first two POS for St Gervais where the important relationship between buildings and landform specific to the vernacular Alpine architecture were not considered. As result the commune of St Gervais is well known in French jurisprudence since its first POS was annulled by the highest administrative tribunal, the *Conseil d'Etat* in 1984, and the following POS, adopted in 1986, was subjected to numerous revisions and finally declared void by the *Préfet* of Haute Savoie in 1996. This followed protests from local environmental associations that too much land had been zoned as constructible in contradiction to the 1985 *Loi de Montagne*. This was intended to reconcile environmental protection and community development in the French mountain territories by only allowing new building in continuity with existing settlements.

Given the difficulty of controlling development in a period of rapid tourism expansion and the need to protect sensitive environments, the political decision was made to shift the development control from the DDE to the local municipal offices and St Gervais created its own town planning department '*service d'Urbanisme*' with a dedicated planner. A new POS was commissioned in 1997 by the mayor from Qualipos, a Parisian consultancy founded by the mayor of Asnieres sur Oise, a lawyer, and which included some members of the team responsible for that plan. Environmental and wild life specialists were included and it was considered that outside consultants would be able to provide a fresh look at urban development without being influenced by local interests and pressures.

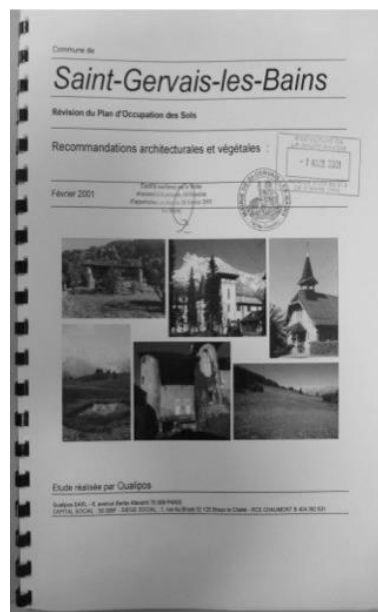

Figure 7. The 2001 POS.

The main aim of the new POS, which was only ratified after four years in 2001 (Figure 7), henceforth referred to as the 2001 POS, was to identify specific characteristics and qualities of the local environment in order to devise rules and design guidance in order to generate new developments which would better integrate in the existing landscape and the traditional built environment. However, a new mayor was elected in 2001 and he did not support the new POS, which belonged to the previous administration and had proved a sensitive political issue with his electorate. It was cancelled and temporarily replaced by the POS of 1986 until the commune developed their PLU which was ratified in 2006 with revisions in 2011, 2012 and 2013 (St Gervais, 2006).

The Last POS

The main aim of the 2001 POS was, through a detailed analysis published in the survey report (figure 5), to identify the specific characteristics and qualities of the local environment in order to devise regulations which would ensure that new developments would integrate with the landscape and the traditional built environment. In order to achieve this Qualipos used a typomorphological approach which has some similarities with recent United State Form Based Codes methodology. This enabled the identification and description of suitable types characteristic of the area, which were then developed into prescriptions for new developments. The process and resulting planning rules are explained in some detail in previous publications (Samuels 1999, Pattacini, 2001). Because of the complexity and diversity of the building types over the dispersed territory of St Gervais the final document took a long time to be approved and included 250 pages of regulation.

At Asnières the POS, which used the same approach, failed because it was too complex to be implemented by staff of the DDE who were essentially administrators with little technical expertise (Pattacini, 1997). St Gervais with its planner was better equipped than most small communes in France to administer a plan and it also access to the services of the *Conseil d'Architecture et d'Urbanisme et de l'Environnement du Haute Savoie* (CAUE), an advisory agency serving each region of France. Even with these advantages the 2001 POS proved difficult to enforce because of the large number of rules related to specific types so that, despite the local expertise, the document became a major political issue with numerous legal disputes resulting from the refusal of planning applications. It was labelled as a '*POS spoliateur*', a confiscatory plan, since it reduced building rights and it encountered strong opposition from the elected communal council. However, although it was only applied for two years the principles of the POS proved more long lasting and have influenced subsequent planning documents as discussed below.

Evaluation

This evaluation is based on a limited number of interviews with key actors in the process of adoption, implementation and application of the POS and an examination of some major projects implemented since its preparation and adoption. For comparative purposes, the choice of the interviewees was informed by the previous research related to the Asnières sur Oise POS (Samuels and Pattacini 1997). The equivalent of the planner in the UK situation is a more complex group of controllers in the French context. In the case of St Gervais the system is less complex and, unusually, the chief of the planning office at the time of the preparation of the 2001 POS is still in post and was able to offer a unique view of its evolution and impact. As has been noted above, the mayor remains a key figure in the French planning system.

The architect charged with safeguarding the architectural heritage of the Department (*Architecte des Bâtiments de France*, ABF) has been involved in the recent development of the

town centre but was not as instrumental as in the Asnières' case where all projects needed his approval because the main settlement lay within 500m of the listed church. An architect in private practice in the commune was also interviewed and it was possible to use the unique "before and after" illustrated panels which the Mayor has erected in key locations to illustrate the positive changes made to the town as part of his long term legacy.

The Mayor

As a key actor in the decision making process of a small commune the present mayor did not support the qualitative 2001 POS commissioned by his predecessor when he was deputy mayor. The rigid constraints imposed by the new plan were extremely unpopular with the local population and landowners, while its power to make or break fortunes made it a powerful political tool in local elections. The mayor considered the detailed prescriptions of the POS inappropriate and he did not defend it when it was annulled in 2003. He took the opportunity of changes in the planning system to replace it by the PLU approved in 2006.

The 2001 POS tended to favour new developments which were a pastiche of the historic spa architecture and this reflects the inclination of the elected members of the council to emulate the traditional architecture rather than encourage a more contemporary style. The mayor is conscious that the promotion of emulating the old will encourage pastiche but for him that is preferable to risking uncontrolled innovative design. In the mayor's opinion this is a safe option, which suits the majority of the electorate and is only criticised by few "purists and aesthetes".

However a vision for St Gervais can not only look backwards but must also build the necessary infrastructure for the future. The exceptions to the conservative rules of the *POS* plan are the new bridge, described by the mayor as a work of art (*'oeuvre d'art'*) with particular attention being paid to its limited vertical impact on the landscape with the lighting integrated in the balustrade to emphasise the horizontal line. This has diverted through traffic to the ski lifts and permitted an ambitious traffic calming scheme to be implemented in the town (fig. 8.). A new swimming pool, designed by a high profile architect, Dietmar Feichtinger, will also be a 21st century landmark.

Figure 8. The new bridge and traffic management in the centre of St Gervais.

The planner

The planner in charge of the commune planning department (*'Chef de d'Urbanisme'*) has ensured the continuity and a long-term vision for the development of St Gervais. Having been in place since 1990 he has a comprehensive understanding of the radical changes in the approach to development control. He refers to the POS prior to the Qualipos work as a *'POS photocopieur'* a generic document fixing some arbitrary rules with no reference to local specificity. The lack of information and underpinning principles to adequately assess and control the quality of new developments was only partly addressed through work undertaken by the advisory architect (*architecte conseil*) of the CAUE, who had undertaken a detailed analysis of the main settlement.

From a professional point of view he considered that the 2001 POS "was a remarkable piece of work", meticulous and thorough, providing a good database of the key characteristics of the existing built environment and that the work undertaken by Qualipos marked a radical shift from generic to specific. The careful analysis of the built environment was comprehensive and enabled a better understanding of the various types of building found in the different settlements of the commune. This work was an important and necessary to enable a shift from crude zoning to specific urban characteristics and building typologies.

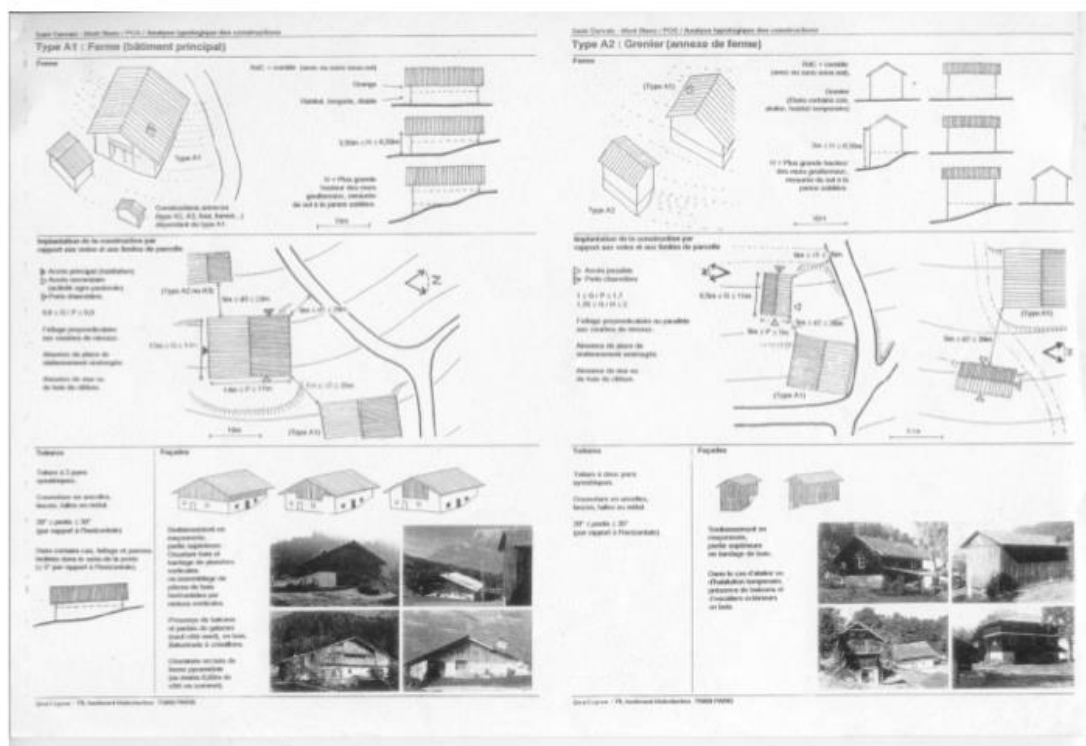

Figure 9. Characteristics of farm buildings (from the survey report).

While the resulting document was noteworthy it was also unrealistic in its ambition of controlling new developments. The value of the morphological approach is not questioned but, in his opinion, it went too far in prescribing details through regulations which were extremely difficult to enforce, especially those related to three dimensions. As the person in charge of assessing planning applications he considered that it was too complicated to use and apply. It was too ponderous to administer and resulted in numerous counterproductive conflicts between the political power and the inhabitants, which proved detrimental to the development of the commune. Rules need to be clear, justified and well explained but also manageable and

understandable. From his point of view an attempt to control everything is never a possibility. (figures 10,11,12).

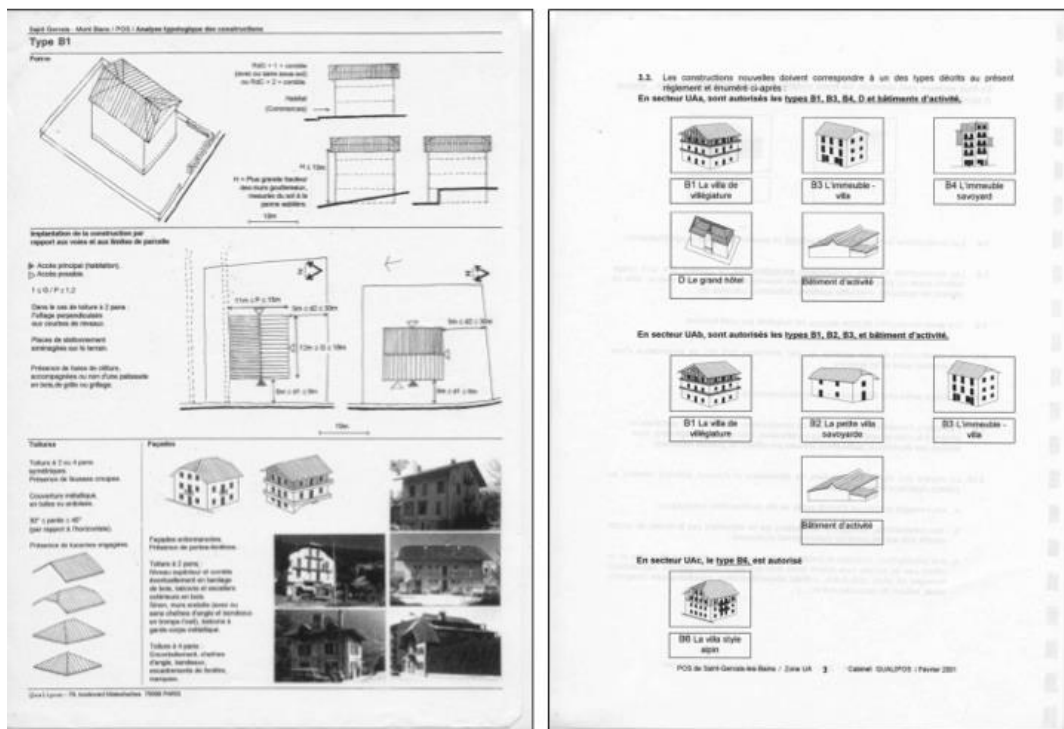

Figure 10. Analysis of Type B1 (from survey report). Zones where B1 type, in addition to other types, is permitted (from regulations).

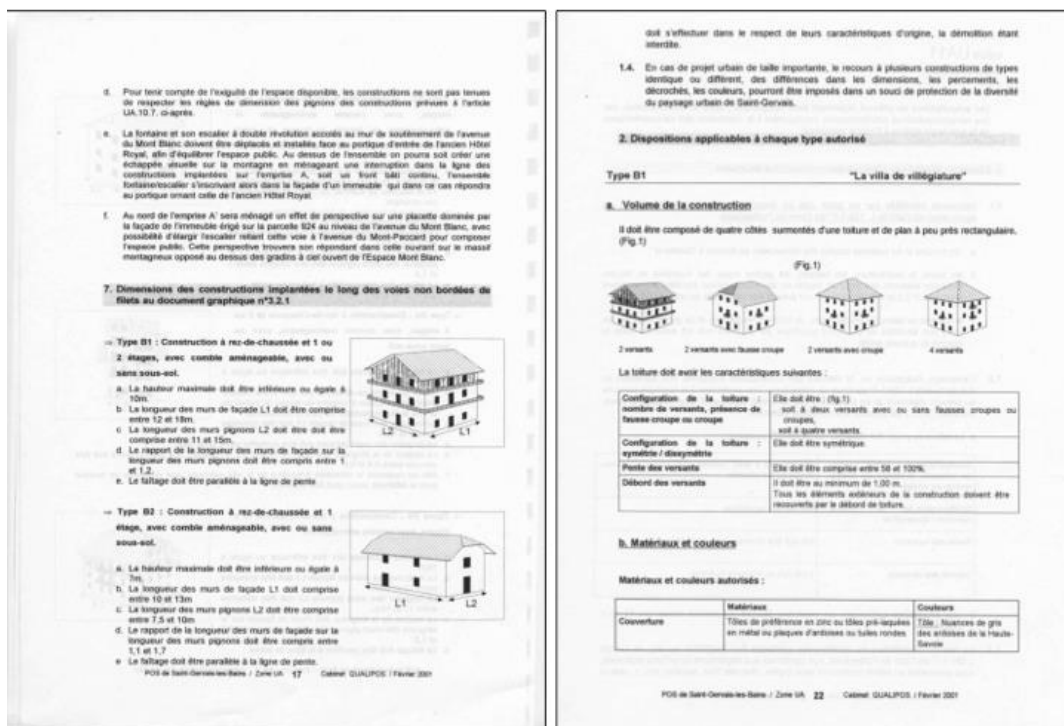

Figure 11. Regulation for type B1 : dimensions, roof characteristics and materials.

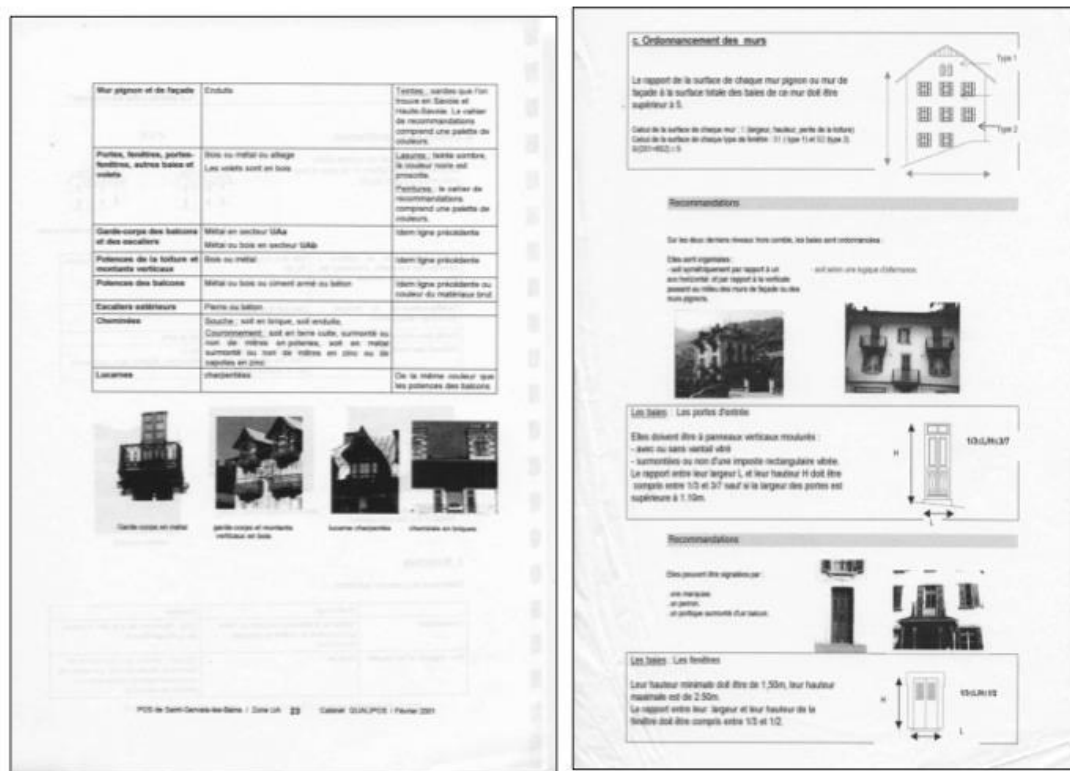

Figure 12. Regulation for type B1: materials and details.

Although the annulment of the 2001 POS seemed to be a backward step, the presence of the same planner ensured the continuity of the key principles underpinning the qualitative approach to urban planning. The vision of a more coherent urban development respectful of the surrounding mountain landscape was also strongly defended by the new mayor. This combination of political will and technical expertise enabled the pursuit of achieving a high quality built environment in harmony with existing vernacular architecture and the natural environment to be continued.

The architects

The ABF has been involved in the commune after the annulment 2001 POS. He was commissioned to produce a typological study of farms prior to the award of conservation grants by the CAUE. He considered that the specific morphological characteristics of these vernacular farms, as described in the 2001POS (fig. 12) are so intimately related to the agricultural function that the type cannot be adapted to modern use for vacation homes without major architectural changes. For example, the living quarters were at the bottom of the buildings while tourists demand the best views so what was a barn at first floor is now the main living room. The balconies for drying purposes were originally unrelated to the internal floor arrangements so that to accommodate present needs, the balcony position on the façade has been shifted to the same level as the living space and enlarged to accommodate outdoor living.

For the local architect, who had been engaged in designing private chalets, the 2001 POS was an important step in changing the attitudes of the 1970s and 1980s i.e. of building without any consideration for the local context. The rigorous approach to the types and forms of vernacular and thermal buildings forced private developers to be more careful and sensitive. He

considered that the main improvement has been the change to the roofscape since flat roofs are no longer permitted. However, he did believe that the strict rules were punishing contemporary architects for the mistakes of previous generations and he was convinced that architects nowadays would not make the same mistakes and are in general fully aware of the importance of respecting the context. He was therefore not in favour of overly prescriptive rules which can be unrealistic because they focus on vernacular types and forms without taking into consideration their appropriateness for modern uses. For example as described in the 2001 POS the volume of the traditional farm building with a large footprint (minimum 12 by 14 metres) was determined by the building having to accommodate several functions which needed to be grouped together as protection against a hostile environment. For his clients, who want a small dwelling for their holidays, these volumes are neither appropriate nor economically feasible. He also referred to the matter of the location and size of balconies mentioned above. As with the ABF the architect's main concern is the overall coherence of the built environment so that his work now includes the renovation of 1970s houses and their cladding according to the chalet typology.

The legacy of the 2001 POS

Although the 2001 POS was annulled only two years after its introduction for reasons discussed above, it has had a considerable impact on development since then. It set some strict rules underpinned by a thorough analysis of the urban morphology and existing building typologies and this proved a turning point in the approach to new development in St Gervais. The morphological approach is a well-established methodology to study the physical form of settlements (Allain, 2004) and the analysis underpinning the regulations highlighted the specific local characteristics, their importance and the need for more sensitive new developments. None of the interviewees questioned the value of this outcome and the planner stressed the importance of the document as a reference source particularly with regard to the detailed classification of the different urban zones (figure 13).

Figure 13. The crude zoning of the 1986 POS, the more detailed identification of specific zones in the 2001 POS leading to the zoning plan of the 2006 PLU.

The key principles underpinning the POS were also adopted in the development of the PLU. The main difference lies in the formulation of the regulations. . The PLU includes far fewer illustrations and focuses mainly on key principles leaving space for interpretation. The planner refers to these as safeguarding rules (*'règles garde fou'*) which will ensure that the most disturbing intrusions into a sensitive context are avoided. What he deems important is an

approach informed by the existing typologies as identified in the qualitative 2001 POS. (figure 14)

Figure 14. The PLU controls volumes which respect the natural topography rather than excessive detail (St Gervais 2006).

For example, traditional farms are orientated so that roof ridges are perpendicular to the contours and this characteristic is now part of the PLU regulations. Hitherto this characteristic was ignored so that an alien geometrical order was imposed on the landscape. (figure 15) Another characteristic incorporated into the PLU is the use of building entrances at different levels according to the topography (St Gervais 2006).

Figure 15. New chalets which respect the slopes compared with extensive cut and fill (top right) to create a flat platform.

For buildings in the *hameaux* the PLU regulations control the relationship with the topography, an insistence on the built area being accommodated within the roof cover (i.e. no

extensions), a width: height (to the string course) ratio of between of 1:1.7 and 1:4 with a maximum total height of 6.5 metres (Ground floor + 1+attic); and a maximum build area of 30% of the plot area. For buildings in more urban contexts the model is the architecture of the spa and for this the PLU specifies maximum height of 9.5 m for hotels in town centres (ground floor + 2 +attic), a maximum built area of 55% of the plot area and the maintenance of a minimum area of open space per dwelling (from 100 to 250m²per dwellings). Specific examples are illustrated below.

Another principle carried over from the 2001 *POS* is the reduction in the size and impact of new vehicle routes by more sensitive alignments and narrower carriageway widths and attempts to group car parking on the edge of settlements. While these measures go some way to reduce the intrusion on the streets and landscape, in the high season cars still dominate the scene.

The projects

In the *hameaux* the emphasis is on the grouping of buildings and their integration into the fabric of the place including considerations given to the natural slope of the mountain landscape. Figure 15 illustrates the contrast between a chalet built on a platform and new constructions better integrated in the existing landscape.

The *Domaine de Crespin* on the outskirts of the urban centre of St Gervais illustrates the reference to the character of Spa Architecture to inform new apartment buildings. (fig. 16, 17) It also demonstrates the effectiveness of rules related to topographical considerations and the amount of open space in relation to the number of dwellings – although this is mainly occupied by car parking spaces. Particular attention has been paid to details including balconies and roof modelling. This new development contrasts with developments before the work undertaken to develop the 2001 *POS* (fig. 6).

The radical transformation to the historic core of the commune made possible by the construction of the new bridge removing heavy through traffic has already been noted. This allowed an emphasis on the visual quality of the building facades even to the extent of using trompe l'oeil windows and trees (fig.18). The replacement or radical modification of the flat roof buildings of the 1970s may not have a strict morphological justification but it demonstrates how a townscape perspective can contribute to the coherence of the street scene (Fig.19). Similarly the *Maison Forte* project is not a strict restoration of the original fortified farm but an imaginative reconstruction which is justified because it meets the need for an iconic new landmark tourist attraction, a requirement which a more authentic restoration could not meet (Figure 20).

Lessons from St Gervais and Asnières

Degree of prescription

In both places those drawings and rules related to an analysis of urban forms, spatial structure and plots were well received. The classification of general building types in their context indicating volume and heights were more problematic to enforce but nevertheless used effectively and emulated at St Gervais in the more recent PLU. The most problematic level of definition appears to be the prescription of construction details, including materials. This was poorly accepted by the users and replaced by the old more familiar generic document. In both cases the urbanist and administrators experienced difficulties to enforce and police the detailed requirements. According to them both plans have gone beyond the manageable threshold with regard to a level of prescription and have been criticised by locals as over regulating. Finding the right balance between a too simplistic, generic and a too detailed prescription must be the key to the success of this approach.

Technical competence

The technical capacity of those who will be left to administer a plan once its authors have departed is clearly a matter, which has to be taken into consideration. St Gervais is fortunate having a full time planner in the commune and, although he admits to having found the regulations onerous to administer, he was quite capable of the work and the POS failed for other reasons. However at Asnières a principle reason for the abandonment of the POS was the inability of the staff of the DDE, essentially administrators with limited technical capability, to administer a complex set of regulations.

Political considerations

In both St Gervais and Asnières the mayors turned to a typomorphological approach in an attempt, in the former, to avoid a repeat of the 1970s-80s modern building boom and, in the latter to prevent the commune becoming another anonymous Parisian suburb. In both places the main aim was to preserve and enhance the 'genius loci' of the place and the morphological approach provided robust principles to support the political choices. It enabled well informed and evidence based judgments to be made in the granting of planning permissions (Allain,

2004). In both cases the main concern was not the architectural merit of the individual buildings but the achievement of a homogeneous and harmonious environment. Tugnutt and Robertson (1987) refer to the need for buildings to be tutored and in the case of Asnières and St Gervais, this tutoring is achieved through a better understanding of types and forms.

Although they were initially supported by the local electorates, it is notable that in both places the mayors who commissioned the plans were voted out of office soon after each POS was adopted. The extent to which the type of plan implemented contributed to their defeat would require a much more detailed investigation. However there is a suspicion that the high degree of specification and the increased cost involved in meeting these requirements contributed to their unpopularity. Of course, in democratic societies all plans need political support in order to be adopted and implemented, whether they incorporate urban morphological methods or not, but it may be that this type of regulation with a high degree of detailed control presents an easy target for criticism.

Economic considerations

The way the St Gervais plan affected the development value of sites has been noted above. Another economic aspect relates to the considerable resources needed to undertake detailed work of the type described, particularly in dispersed commune. The fate of Qualipos is instructive in this respect. The firm was established following the preparation of the Asnières POS by the mayor of that commune, a lawyer. His professional partners were notaries (a profession which had been involved in town planning from the middle ages) and the Asnières POS received a *Prix National d' Innovation* of the *Conseil Superior du Notariat* in 1995. The work had been undertaken by a team of UK University staff and postgraduate students and Qualipos proceeded to prepare plans for a number of small communes (Aumont, Molitg-les-Bains, Thauvenay, Chateau Rouge etc) in different parts of France with members of the same team working on a *pro bono* basis supported by French recent graduate interns on the minimum wage (*SMIC*). Even with such a low cost base the fees from the small communes were not capable of supporting the work and soon after St Gervais Qualipos stopped trading. Unless less labour intensive methods can be devised, perhaps the use of new technologies, any projects of this type must be aware that there is a demand for resources which goes beyond that needed for more generic plans, although it must also be taken into account that once the labour intensive analysis has been made a resource is available to inform future work as has happened with the St Gervais PLU.

Conclusion

Beyond the mundane, but critical, considerations of cost and competence both St Gervais and Asnières confirm that an urban morphological approach offers a rigorous method of acquiring the sound understanding of local identity essential to achieve high quality, unique environments. However, the shift from description to prescription requires a great deal of consideration as to the appropriate level of definition to ensure a consensus between the professionals and the users as well as the presence of the technical ability to implement the instrument.

In both Asnières and St Gervais the detailed level of the regulations was detrimental to the success and long term application of the plan. In St Gervais the less prescriptive and more flexible PLU has so far proved more resilient in application because it enables some room for interpretation and allows a degree of discretion in decisions. The local plan has a political impact and is a mediator between the different interested parties and interests. It is a tool to reach a consensus between the State concerned with global environmental issues, the inhabitants dependant on the economic health of the local area and, at St Gervais, the tourist looking for a mountain experience. The difficulty is to get to the right level of control in order to reach this consensus, which allows economic development without compromising local identity

Spatial patterns of urban growth in Xi'an, China: a fringe-belt approach

Yunying Ren, Kai Fu

College of Architecture, Xi'an University of Architecture and Technology,
710055, Shaanxi Province, China. E-mail: renyunying@hotmail.com,
973412445@qq.com

Abstract. *The fringe-belt concept, though widely investigated in Western cities, has hitherto attracted little attention within Asia. Building on a recent investigation of the fringe belt associated with the wall constructed around the small, compact Chinese city of Pingyao in the Ming dynasty, this paper explores fringe-belt development in one of China's major urban areas – the former capital city of Xi'an. Like Pingyao, Xi'an has a fringe belt associated with its Ming wall but, unlike in Pingyao, this fringe belt is deeply embedded within a metropolitan area and has been subjected to major pressures for change, especially since 1980. The development of its inner fringe belt, especially in the course of the first half twentieth century, is examined. Its significance is considered both as a heritage feature and, in very broad terms, in relation to the city's growth farther out. Brief comparisons are made with the conclusions of fringe-belt studies of Western cities.*

Key Words: *Xi'an, city for, city wall, fringe-belt, Period of Republic of China.*

Introduction

The significance of cross-cultural research has been underlined recently in the field of urban morphology (Whitehand, 2012), including in relation to the fringe-belt approach (M.R.G. Conzen 1969, Whitehand, 1967, 1988, 2004). A comparative study of a Chinese and a European fringe belt has recently been undertaken (Conzen et al., 2012) and, from a different standpoint, Berlin and London have been compared (Fehl, 2011). Frequently two or more cultures are embedded in a single city (Whitehand, 2012): Istanbul in the cultural convergence zone of the occidental and oriental is a striking example (Kubat, 1999). A number of traditional Chinese cities have been examined using approaches honed in the West. Guangzhou, Beijing and Nanjing are examples (Whitehand et al., 2011, Conzen, 2012). In several cases the mixing of Chinese and colonial aspects of urban form have been examined (Whitehand et al., 2011).

In this discussion of my work I propose to give particular attention to the fringe-belt concept within a Chinese cultural context. In Xi'an, fringe belts that developed in relation to traditional urban cores are now deeply embedded within a major metropolitan area. The extreme conditions that Xi'an has experienced in the course of its long history from flourishing national capital through a long period of greatly reduced size as a provincial capital to two short periods of war devastation and, most recently, major regional growth centre make it substantially different from any cities that have hitherto been the subject of fringe-belt analysis.

Conzen describes a fringe belt as "a belt-like zone originating from the temporary stationary or very slowly advancing fringe of a town and composed of a characteristic mixture of land-use units initially seeking peripheral location. ... In towns with a long history this geographical result emerging gradually from these dynamics is often a system of successive, broadly concentric fringe belts more or less separated by other, usually residential integuments" (Conzen, 1969). In pre-industrial cities many city fringe belts are associated with city walls.

Xi'an, located in north-west China, recommends itself for study in part because it is a major traditional city with one of the most complete ancient defensive works in existence. These city walls and the fringe belts associated with them have become embedded in the modern city. The evolution of the fringe belts of Xi'an, particularly the one associated with the city's late-fourteenth-century Ming-wall, will be investigated from 1911 to 1949. This period includes a number of major changes: the substitution of the new regime of the Republic China for the Qing dynasty since 1911, the Sino-Japanese War between 1937 and 1945, and the Communist Revolution in 1949. These twentieth-century changes occurred within an urban morphological framework characterized by a number of significant cultural changes, each of which has left a significant legacy on the ground. The fringe belts of the cities were investigated within the multiple city walls since the fourteenth century, which formed four layers fixation lines from the interior to the exterior including the Drill Ground with wall and moat, the Man city wall, the Ming wall and the Gate city wall, each associated with fringe belt features. (Figure 2-1).

The earliest of their fringe belt to be considered here marked the period of the governance by the minority Man people in the original area of the Han nation, the Man city occupied the north-east quarter of the Ming city wall between 1645 and 1911, and the new wall in its west and south along with the main street, far beyond the dominant city form of symbolism by the Fengshui, which served as a sort of cultural believe in the harmonious of the cosmos since then as well as the Muslim community layout in the northwest embedded in the Han communities till to now (Fig 2-1). It was essentially apartheid between the Man and the other nationality, so that the core of the city was composed of division quarter layout within the Rectangular City (Fig.2-2). Besides, it exhibited a particular process of the city form with the feature of function of land use, street fabric and the street block, which the modern industrial function of land use emerged since 1911 as well as adapted to the needs of the social-economic development at the moment which was seldom affected by the culture from abroad directly. This is different from the previous general cognition of Chinese traditional city, such as Guangdong which the city construction were impacted by the colonization from the West with the trades and industries more or less.

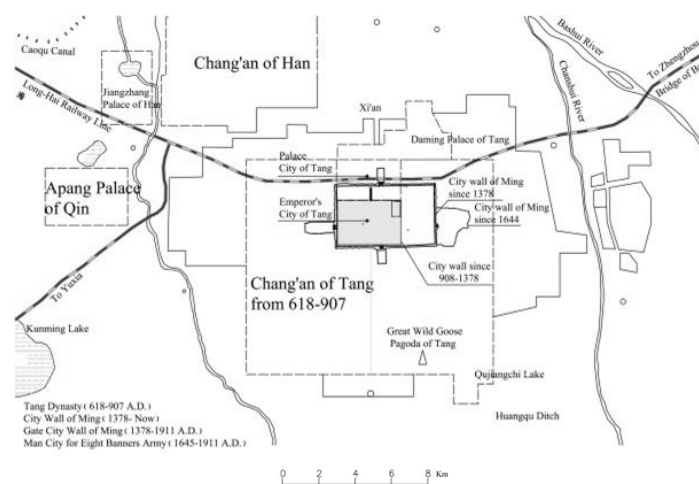

Figure 1. The historical site of Xi'an. (source: Historical Geography of Chinese City, Edited by Ma Z. L., Shandong Education Press, Otc 1998).

The historic-geography background of the city form of Xi'an

Xi'an experienced the development of its fringe belt within the city wall re-development since 1378, which was, inter alia, the Emperor city, once an important part of the capital of Tang dynasty since 618 A.D. (Fig 1, Fig 2-1, Fig2-2). The city of Ming dynasty had been enlarged to the north side and east side of the previous city since 1378, which had been built about four

hundred years in the original site of the Emperor city since the end of the Tang dynasty in 907 A.D.

According to the measured data, the perimeter of Xi'an city wall of Ming is 13.9 km, of which the length of east wall is 2.89 km, west is 2.71 km, south wall is 4.26 km, north wall is 4.26 km. The area includes the wall thickness is more than 11.5 square kilometres (H. Wu, 2000). The four gate cities had been built in addition in 1644 in order to strengthen the military fortification of the city. But it could not prevent the city pledge loyalty to the Emperor of Qing since 1645. The Man city was the production of the changing Dynasties since then, which was the place for the army of Emperor's tribe and their kinsfolk living. It was built in terms of the tenet of the prior of the military needs with the closed city wall within Ming wall till to the year of demise of the Qing Dynasty in 1911.

The city of Qing dynasty was divided into 4 parts within the Rectangular City basis on the site of Ming city, by the 2 perpendicular arterial streets linked the 4 city gates and cross at the centre point, namely the bell tower, which is the landmark for surveillance in the city. From the bell tower to the four main gates, the road was named by the director of the gates, namely East, West South, and West Broadly St.. The Man city in the northeast part, which the measured perimeter of its city wall is 8.77 km, the area is 4.8 square km, accounting for about 42% of the area to Xi'an city (H. Wu, 2000) (Fig 2-2).

The other part of the city, including the northwest (NW), southwest (SW) and southeast (SE) accommodated the residential area with the civil administrative department of the provincial and the regional located among them and around the Man city embedded in the corresponding residential area. Besides, the Muslim communities involved about 50 000 people, assembled in the most area of northwest part, while some new institute emerged in the late Qing dynasty since 1903 such as the hospital with the western medicine, primary school and mid-school with the modern education idea, which were belonging to the church, always near to the city wall or in the Gate city.

But it dramatically changed after 1911, when the government of the Qing Dynasty was replaced by the Republic of China. The Man City was destroyed completely, when the Eight Banners Army loyal to the emperor was defeated by the army loyal to the Sun Zhongshan who is the first president of republic of China and advocates democracy in China. And the Man National people were escaped far from the city for the fear of implicated as the enemy to the new government. Since then, the people of Man nation were almost disappeared in the regional of Xi'an. Obviously, the Xi'an City built-up area is reduced to a minimum level in 1911, and it became the turn-point of the evolution of the city form of Xi'an till to 1949.

The year of 1949 should be the watershed with the development of Xi'an city since modern times before the national industrialization period effected by the previous Soviet with the rapid development of the planned economic system. In the view of the comparison, the development of the city is very different from its spontaneous evolution in the previously period before 1949.

Figure 2-1. Map of Ming dynasty 1624-1644.

Figure 2-2. Map of Qing dynasty 1645-1911.

Background of the delimiting about the period

In terms of the terminology of fringe-belt studies, it is characterized by the relocation of individual functions from the centre to the periphery (M.R.G. Conzen, 1960). Obviously, although the processing typically in accordance with the methods, Xi'an experienced a different way in the city form for it proximately division quarter area developed within the individual quarter part of the city rather than a comprehensive commercial centre within a kernel area, because the provincial guild accumulated in the southwest quarter part with the commercial market and shop distributed in the northwest and southeast part as well as the Muslim residential area. . Indeed, before 1911 the paramount important military centre is the Man city for the Eight Banners Army, which is the domicile of army served to the Emperor located within the quarter area in the northeast of the main city. (Fig 3)

There exists a wealth of information of historical of Xi'an, which essentially make it could be understood about the fortification, streets fabric, some of the significant organization. But it lacks true cadastral maps showing individual plots and buildings for the entire urban area and city fringe as well as in Europe. However, quite a true ground plan of the research area of Xi'an has become available since 1893, especially the Ordnance Survey maps in 1934 and blueprint map in 1939, as well as a plan showing the situation of the area before 1949, even the plotting scale is not good enough to show some details information of the fringe belt. They have created the research opportunity for morphological as well as the contribution significantly in the present study.

Fortunately, the Ordnance Survey maps in 1934 by the Land Surveying Bureau subordinate to the General Headquarters, contain detailed information: for example, the legend of the new district is different from the built-up area which marked clearly in the map with the distinct boundaries of the land use and building. So the new area built after 1911 is possible to be laid out on the map (Fig 3) as well as the methods with the map of 1939, 1949, which is helpful to the city plan analysis in the view of the approach of fringe belt.

For the purpose of the explanation of the town plan as we find it today, as well as the contributing of the cartography exhibited the exclusive character in the process in accordance with the changes of the fringe belt with the information of the Map of 1934, 1939 and 1949.

In terms of the major influencing factors such as the Second World War and the post-war reconstruction, yet the milestone events within the period during 1935 to 1949 such as the railway coming into use, as well as the incidence of modern cartographic sources, make it expedient for the purpose of the analysis to adopt certain contractions and subdivisions as shown in the following table:

(1) Pre-railway period (1911-1934)

- (2) Railway period (1935-1949)
 - (i) Pre-Prior War period (1935 -1939)
 - (ii) Anti-Japanese War period (1939 - 1945)
 - (iii) The post-war Reconstruction period (1945 – 1949)

The inner fringe belt within the Ming wall from 1911 to 1934

With the demise of the Qing Dynasty, the city was completely destroyed during the last fierce fighting war in 1911, the west wall and the south wall was pushed to the ruins. Man city became the potential activity area for the redevelopment within the Ming city with the rectangular fixation line by its wall and moat of the Drill Ground of Eight Banners Army. Comparatively, the fringe belt area in the other three areas kept the spontaneity process of themselves in the corresponding corner within the city wall (Fig 3).

There existed important information could be understood with the comparison of the map of 1893 and 1934. The map shows the distinct difference of the street fabric within the Ming wall, which could be discerned the organic area with the residential building excluding the Man city in terms of map 1893, which the area could be judged forming spontaneity since 907 AD when the new city was built on the site of the Emperor City of Tang dynasty for people to live in, till to 1374 when the city began to expand to the north and east out of the prior one in the beginning of Ming dynasty. (Fig 2-1) and finished in 1378.

The condition of the fringe belt of Xi'an in 1911 was unusual. Almost the entire Man city (perhaps the nearest equivalent in the West would be a massive medieval castle), occupying the north-east corner of the Ming city, was in ruins. The fringe belt of Xi'an between 1911 and 1934 could be judged by the map. The Man City wall became a fixation line especially the west and the south wall of it except the other two sides of the original Ming Wall, additionally, the wall and the moat of Drill Ground which was the original Prince Mansion of Ming became the other fixation line either. The characteristic development in the Man City area shows typical features of fringe-belt formation, with the land use of institutions, commercial and public facilities (Fig 3).

Meanwhile, the un-built up area mainly located in the other three corners outside the Man City but within the Ming city wall, especially the northwest corner which was adjacent to the inner wall and was hard to be used because where there was the land of low-lying as well as the water pollution and unfitted for living at the moment.. A new area assembled of public services (administrative, military, public entertainment facilities and the Western Church) developed between the west and south Man city wall along the North Broadly and East Broadly St. and the previous Drill ground after 1911. Besides, in terms of the official statistics, in 1929 industrial development was at a low level, mainly consisting of the handicraft industries (Statistical report about the construction of Shaanxi, 1929) , which were fusion in the residential area by using of existing residential buildings with the first floor for shops ground or the front room of the house for the store, without the contribution to the outwards of the land use.

Some new land use with the new building types became the dominant appearances of the fringe belt development. For example, the land use of commercial with the corridor along the north side of the main road along with the south wall of Man city (Compilation Committee of Local chronicle, 1996), namely East Broadly St., spread from the point of the Bell Tower to the East Gate of the Ming wall since 1912 under the support of the government. Besides, the institutions near to the built-up area were exhibited forming the arterial ribbon along the East and North Broadly St., such as hospitals including the Red Cross Hospital in 1912, Land Army hospital in 1913, Shaanxi Christian Guangren hospital in 1916, the vehicle repair factory as well as the new churches with primary school or the hospital dispersed along the south and west of Man city wall, such as Young Men's Christian Association (1914) and the Baptist Church (1914) distributed along with the East Broadly St., and Protestant Episcopal Church(1916) with the primary school distributed along with the North Broadly St.

Furthermore, the garrisons with the affiliated facility places near to the new government which based on the site of the drill ground of Man city, yet which had been the mansion of the Prince of the Ming as well as the institutes such as the Protestant Episcopal church, primary school and the government department along the North Broadly St. from the Bell Tower to the north city gate directly formed the arterial ribbon. Meanwhile, there emerged the public garden or the park for the memories of the people dead in the war, and a several mulberry fields etc., which most of them scattered in the Man city around the Drill Ground and also sparsely in the north-west and south-east corners of the Ming city as well as some cemeteries.

The initial phase of fringe belt formation in the extramural area is also evidenced. Some new land uses developed outside to the Ming wall, dispersed within agricultural land, which included cemeteries, nursery gardens, a school and a Seventh-day Adventist Church. The four stretches of wall are similar in character with the villages scatter around it in accordance with the distance of the agriculture work, partly of the peasants lived in the four Gate city. Industry was beginning to develop adjacent to the railway along the northern wall by the end of 1934 (Figure 4), though there was still little evidence of industries other than those traditional handicraft of Xi'an. The plots using by the government department, some institute or the warehouses among the Muslim residential area were replaced simultaneously while the initial of the fringe belt development within Man wall.

The inner fringe belt of the Ming Wall 1935 to 1949

1935-1939

The railway link to Xi'an from the Lianyungang of east China in 1934, later developed to Baoji to the west of Xi'an in 1937, started to become the lifeline of transportation during the war years. The railway station was built just north of what had been the Man City, which connected to the city from a new gate in front of the station namely Zhongzheng Gate. Fringe-belt development began near the station as institutions began to take up sites along Zhongzheng Road. Again the residential area accumulated immediately, mainly between the north of the Drill ground and North wall as well as the northeast part of the Ming wall and near to the train station. The fringe belt within the Man city wall had formed 2 areas including the area near to the built-up area and the opposite far beyond the area and near to the wall. The area near the station and along the road developed quickly, linking the railway station directly to the area south of it. It essentially formed another arterial ribbon of fringe belt along (Fig 4).

The railway line linking Xi'an from Lianyungang of Jiangsu province in the east coast of China in 1935 made it possible for mass transport of raw materials and products, promoting the progress of the industrial development base. The railway became a new fixation line, along which new factories developed. A few factories were built near to the north side of the railway line, including the flour mills, textile factories and electric power plant (Fig 5). It essentially formed the extramural inner fringe belt which developed with the benefit of the railway. However, still in 1949 there were a large number of the villages, schools, agriculture test areas and cemeteries as well as the Seventh Day Adventist Church sparsely distributed along the outside of the Ming wall.

Inside the Ming wall, the grid fabric of the street adapted to the requirements of the motor car. The street pattern of the Man City, with its straight and regular streets fabric, acted as a morphological frame. However, although the main street pattern was regular it contained within it an irregular, organic pattern, reflecting the adaptation of the interiors of street blocks. Thus within these street blocks it is possible to recognize adaptations from the layouts feature of traditional Shaanxi dwellings: arguably a process with antecedents at least as far back as 907 A.D..

In contrast, the street block met the needs of the land-use pattern of the platoon courtyard model in the area of Man City, with new functions, such as a stadium, institute of railway administration, and new types of residential buildings. This was a relatively rapidly period of development period. This was especially influence by the extension of the railway line to Baoji, which is a major city in the west of Shaanxi and a traffic node linked with the south-west and north-west of China as well as the east of Shaanxi Province. So, it shows that the construction of the city and its industry have achieved remarkable development over the 1935-1939 period.

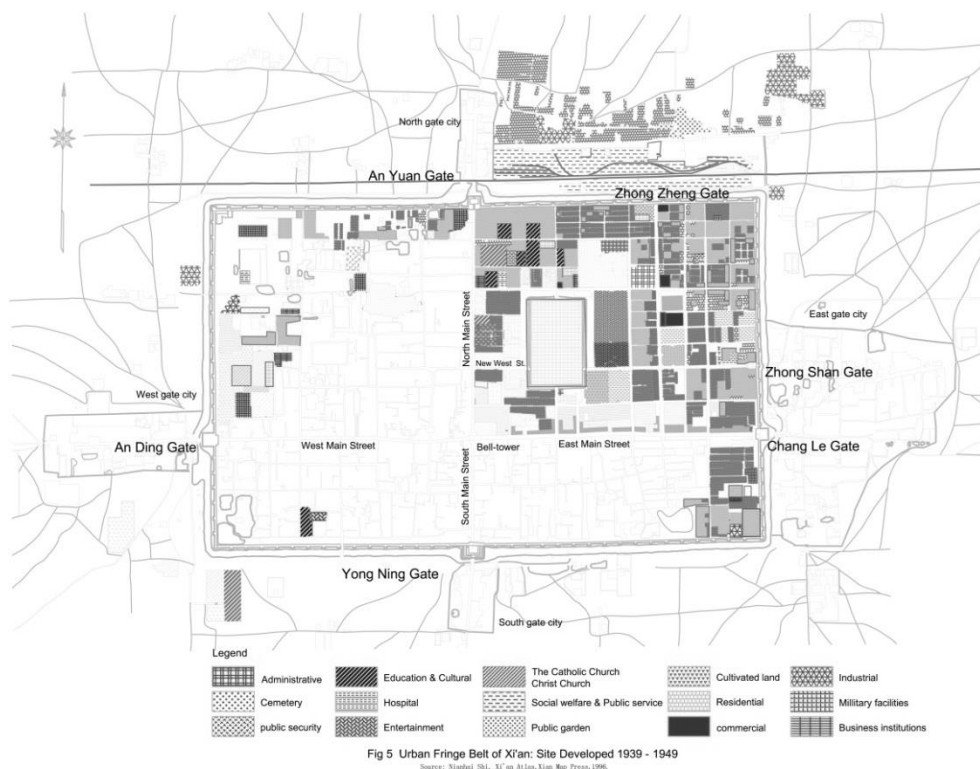

Figure 5. Urban fringe belt of Xi'an : Site developed 1939-1949.

1939-1945

However, there was also another important aspect of development at the end of 1935-39 and following that period. The Japanese invasion of China led to the migration of industry for reasons of national security. Japanese bombing caused great destruction between 1937 and 1944, especially to industry, although a good deal of the handicraft industry was absorbed into residential areas.

During this exceptional period the fringe belt was filled with new types of residential buildings, as well as an orphanage, a hospice, parks and some factories and barracks. With the occupation of eastern China by the Japanese, Xi'an became an important hub of transportation supply, munitions and civilian production. Along with the large number of funds and population flowing into Xi'an, various enterprises set up and stimulated a short period of city growth. There

was a mixture with the damage by Japanese bombing and the initiation of city projects, such as road widening.

According to incomplete statistics from the Republican archives in 1942, at least 79 industrial enterprises came into existence in this period. However, this had a minor physical impact on the city, for most industrial premises were workshops that were absorbed into residential areas.

The railway line was a significant contributor to the development of the extramural fringe belt at this time. This part of the fringe belt comprised the station and associated other railway buildings and track, a few factories as well as the original villages and cemeteries, and some new institutions including a school and a church.

1945 to 1949

After 1945, the Kuomintang troops and their families withdrew from Xi'an. In addition, a number of factories of national importance returned to their pre-war locations with a decline in population in Xi'an. City development activities mainly concentrated within the Ming wall during the period 1945-1949. At the same time a plan was produced for the post-war city.

The commercial centre formed in the vicinity of the main street that linked the east gate to the bell tower. The new administrative and military institutions sited in the fringe belt which was mainly close to the main street, although some departments occupied plots in the built-up area inside the Ming wall.

The residential units in the Man city area were very different from those in the other three areas. The block of residential units was more uniform in the Man city area and more adaptive to the needs of vehicle echo and leading a quickly development and an obviously evidence in the development of the fringe belt with the modern features, such as the new type residential building make the block with the shapes of narrow rectangle instead of the traditional residential block with the irregularity and organic texture. Such as the Qixianzhuang, which the high quality residential area at the moment, leading a new type of the platoon courtyard and became the model of the construction, and the similar street block could be found in the area near the train station.

Conclusion

In this paper, findings on fringe belts in Western cities are beginning to be added to in the very different cultural conditions that exist in China. The features of the fringe belts of Xi'an, mainly within its Man city wall, have been examined. The development processes associated with the fringe belts in the period 1911-1949 have been the focus of attention. There are more than twenty cities in China with the Man city walls. The subject of city walls developed inside existing walled Chinese cities deserves greater attention.

The processes of fringe-belt formation and modification have been identified (Whitehand, 1967). Modification has included plot repletion and slum clearance. In the phase of fringe-belt formation after 1911, some new land uses developed between the Grill Ground and the Man city wall. Subsequently some land use, including agricultural plots, a park, a military site and an asylum, were replaced by new functions.

The locating of the railway station outside the northern Ming city wall in 1935 gave major impetus to the growth of the Ming fringe belt on that side of the city. This accords with findings in Western cities, such as Newcastle upon Tyne. An arterial ribbon formed south of the station along the new main road linking the station to the interior of the Ming city. Here there developed residential buildings, factories, banks, markets, entertainments, and institutions.

There is potential in Xi'an for further exploring the effect on the urban landscape of internal cultural differences within the city. The case of the Man city within the Ming city has been considered in my talk. In Xi'an the Muslim residential community has kept its traditional

character over a very lengthy period. In addition land uses related to Western culture have become evident, such as schools, churches, hospitals and charitable organizations. The inter-relationship between such developments and the fringe-belt concept are a significant topic for further investigation.

Abstract. *Urban morphology of cities in the Middle East and Central Asia has been of great interests to academics from various disciplines. Through centuries of development Iranian (Persian) art and architecture contributed to what is called now Islamic cities. Isfahan school of urban design has particularly played a significant role in creating to be highly influential in development of Islamic cities in the region. We discuss how establishment of this new school of thought on Islamic cities in 16th century (concurrent with Renaissance) influenced the way we think about cities in the Middle East and Central Asia today. Using content analysis and direct observation as our research methodology we investigate urban fabric of Isfahan- the capital of the Isfahan region in Iran and once its most largest and glorious city in order to extract the conceptual and practical lessons about traditional urban morphology and advocate their importance and relevance for the contemporary urban development practices in Islamic cities.*

Key Words: *Urban Morphology, Isfahan, Urban Design, Islamic Cities, Morphological Integration, Iranian Art and Architecture, Samarkand.*

Overview to Isfahan Urban Transformation from a Medieval City towards an Avant-garde Metropolis

It can be argued that Isfahan's central position in Iran preconditioned it to become the capital of two major dynasties, the Seljuk (1037–1157) and the Safavid (1502–1736) dynasties. Its dual function as an emporium and as a capital manifested in Bazaars and in the courtly buildings that gave Isfahan the reputation of an oriental Versailles (Jayyusi et al., 2008). Given the geographical position of Isfahan at the center of the Iranian plateau, it has been known as one of the most important trade centres of Iran. This position occasionally makes it the bridge between the East, West, South, and North. According to Golombek (1974) Isfahan's urban development shows three phases from the early history of Isfahan to the contemporary era:

Late Sasanid to early Islamic (7th–8th centuries): the satellite villages. During the first Islamic century Isfahan consisted of two small settlements (Jayy and Yahudiyyah) and a large number of villages around the Zayandeh-Rud. The pattern of Isfahan city, like other Iranian desert cities, was based on the transformation of farming lots into urban residential spaces. The irrigation network kept its form as a network of public spaces running through the streets and alleys. Although the primary function of the irrigation systems was to supply water for agriculture, it has also defined the city layout and its urban evolution.. Privately owned farms were divided

into smaller lots of land for residential buildings (Estaji and Raith, 2012). Mehryar (2007) believes that the city of Isfahan was originally the result of the amalgamation of fifteen villages.

From 8th to 15th centuries (early Abbasid to Safavid) the villages eventually amalgamated and Isfahan became a walled town: The next major physical development happened during the Buyids when Isfahan was walled. The exact date of the construction of the defensive wall and its citadel is unknown. However, Muqaddasi, writing in 985, describes Isfahan as a walled city with twelve gates". As soon as the city was limited to its surrounding walls, it was socially and physically divided to several neighbourhoods called Mahalleh (Golombek, 1974, Sarraf, 2010). Mosque (religious space) and Bazaar (economic space) were the two main urban elements for the formation and direction the growth of the city, similar to other Islamic cities. The first mosque, in the mid-seventh century, served a symbol of victory and Islam, within the Jayy's walls (old Isfahan). The mosque was the central urban space, as the city formed and expanded around it; it sparked the development of Isfahan into an early Islamic metropolis. In the early Islamic cities the mosque was not only a place for religious purposes, it served functions of a court, a school, a place for discussing and debating, and a place for announcing the Islamic governmental orders. In other words, it was a political, social and religious centre and consequently the centre of the city.

The main mosque of Islamic city was usually located near a large plaza (Meydan), main routes were connected the main meydan to the city gates. Commercial spaces were usually located on the sides of those routes near the city centre and around the main Meydan (Kheirabadi, 2000). Figure 1 presents a schematic model of Islamic cities.

Figure 1. A schematic model of Islamic city (Kheirabadi, 2000).

In Isfahan, the complex of mosque and surrounding spaces and bazaar formed the main structure of Isfahan city during the centuries. The Isfahan bazaar had three major developmental steps after the advent of Islam in Iran: First is the formation the old Meydan and surrounding bazaar that connected the Jayy and Yahudiyyah (Two initial nucleuses of old Isfahan) together. The bazaar organically grew around the old meydan and the Friday mosque (Pourjafar et al., 2014). From 11th century Isfahan evolves towards becoming a prominent Islamic city. Saljuqid was a brilliant period for Art and Architecture in Isfahan, when Isfahan became the capital of Persia (Iran) for the first time. Many of the most important monuments in Isfahan such as the great dome of the Grand Mosque and some important Minarets were erected during this era. The main streets of old Isfahan usually connected the city centre (old meydan) to the gates. These

covered routes had another function; they were bazaar as a structure of Isfahan urban in Saljuqid era. The form of City wall and bazaars followed the organic form of topography and water routes. In the Timurid period the city organically developed further; the city wall expanded southwards, the Isfahan bazaars grew and some new neighbourhoods were formed (Pakzad, 2011). This period sees Isfahan as well developed and quite prominent on the map of the medieval cities of Asia (Babaei, 2008) reflecting blossoming Iranian art and architecture of the time.

From the 15th century, from Safavid era, Isfahan emerged as an avant-garde metropolis became the capital for the second time during Safavid. Shah Abbas the Great (1587-1629) moved his capital from Qazvin to Isfahan and developed Isfahan for its new role. In general Safavid's strong central governments had plans for their capitals, for example, Qazvin shows some examples of new urban interventions. But Shah Abbas's ambitious plans for developing Isfahan were realised in form of large-scale urban public places, new boulevards and architectural monuments. Naqsh-e Jahan meydan and its surrounding buildings were erected for the governmental function and the straight Chahar-Bagh Street connected the old city to the royal palaces (Hezar Jarib) on the other side of the Zayande-Rud. Isfahan's development before Safavid was organic and slow during centuries of organic growth but it changed during Safavids rule as the city developed according to a planned urban design based on the new Cartesian geometry. Development of art and architecture in the city of Isfahan reached its peak and set examples for other cities in the region. Complementary to large-scale urban plans, at this time a new period in Persian architecture emerges bringing rich, sensationallly coloured and imaginative details developed by the predecessors into meaningful ensembles of immense scale and grandeur (Pope, 1965) that was later referred to as the Isfahan School of thought by researchers such as Habibi and Ahari. Figure 2 presents the morphological development of Isfahan.

Perspectives on Isfahan School of Urban Design

Architecture was always a physical symbol of philosophical thought of men. The Art and architecture of Iran was being developed from centuries ago had its mark on the Middle Eastern cities. For example, Samarkand city, the former capital of Uzbekistan repeats a particular city-form and conceptual underpinning of Isfahan, and is ultimately called "the Isfahan of Central Asia (Shea, 1995). This school is important in the field of urbanism because related achievements formed earlier than Renaissance and Baroque in Europe. The famous practice of Iranian art and architecture only reaches its climax in Safavid era, during which their capital, Isfahan, became a city-scale scene for statesmen and artists to exercise their ideas, religious, philosophical and mystic beliefs in architecture and urbanism, supported by a strong central government that also was a religious leader. Architecture/urban planning was more than a mere aesthetic experience and indeed was symbolic of greater truth of the relation between human and God (Shakiba, 2013; Ardalan, 1973). In fact, the Isfahan School started before Isfahan became the capital and in other Iranian cities such as Qazvin and Tabriz. Shah Hassan in Tabriz and in Qazvin by Shah Tahmaseb (two processors of Shah Abbas in Safavid ear) built Friday Mosque, meydan, bazaar and new boulevard in order to boast their governments' power, economic, social and culture of in their capitals, which were Tabriz and Qazvin respectively.

Iran's traditional architecture and art originated from monotheism and accepting divine unity. God created the world based on discipline, order and beauty. Iranian architecture was inspired by order. Architecture tries to restore order in environment; the traditional architecture aims to place human being in God presence by creating order in space. These Islam Gnostic aspects establish Islamic art foundation. Clearly, harmony, proportionate and continuity in spaces are pleasurable and chaos, disorder and visual disorganization are inconvenient (Tavassoli, 1992& Ardalan, 1973). The city form represented a composite of world views and cultural idioms and nevertheless expressed an idea about the city as 'the face of the earth', 'the

mirror of the world', 'the garden of souls' etc. Statements as such are compared to the poems of the Sufy mystics that reveal conceptual essence of the Islamic art and architecture that addresses the search for order and harmony in the natural world, the intangible world, the human soul and the city. Such principles are repeated in cities that either are part of Iran or influenced by the Iranian culture, art and architecture. For example Samarkand that represents the same principles (Shea, 1995). Concepts of unity-pluralism and order-chaos are of the common fundamental characteristics in art and architecture that can be seen as of the architectural tools for forming cities, buildings and gardens that are the mirror of god on the earth. Both are manifested by geometric patterns. Figure 3 presents examples of geometric patterns for creating totality and unity in Islamic art and architecture.

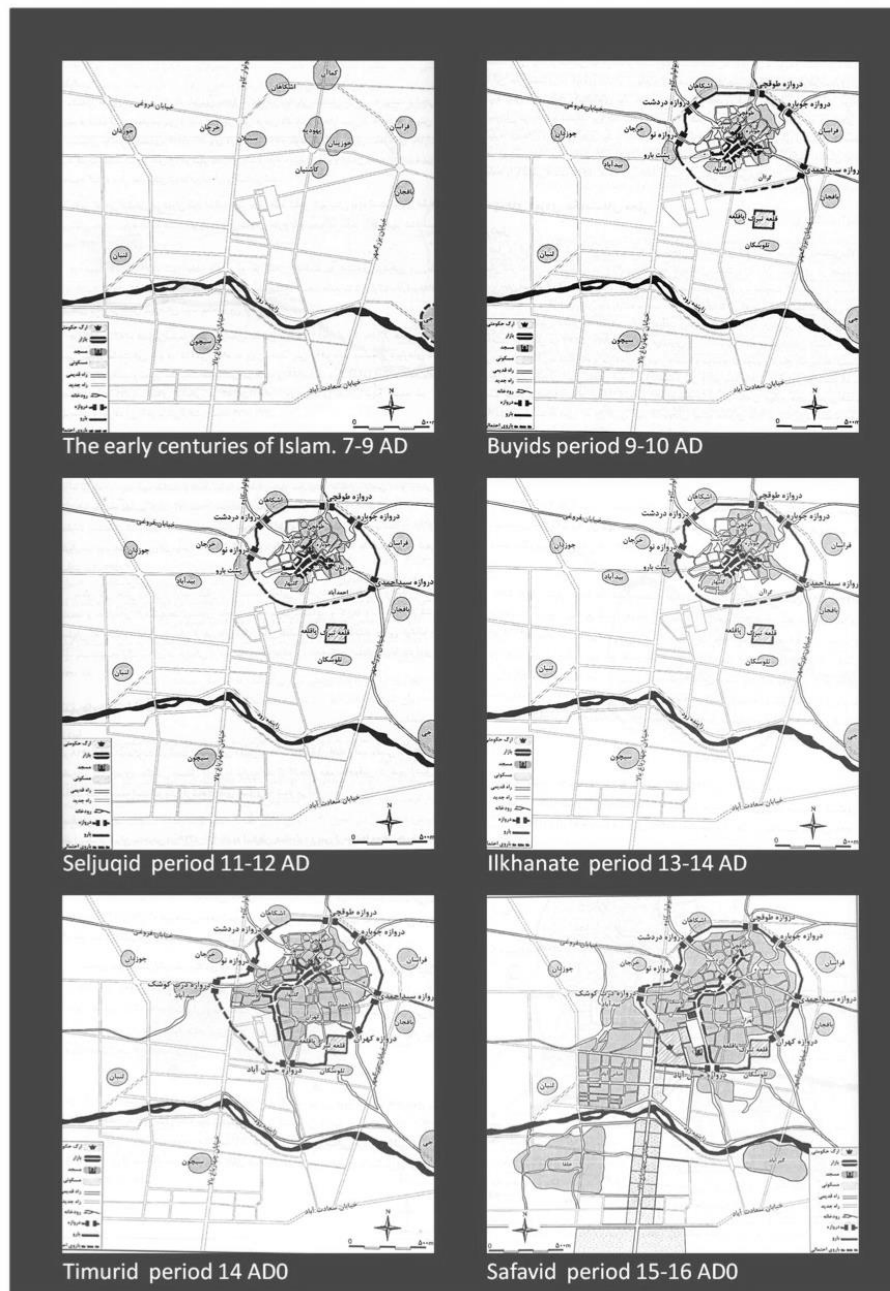

Figure 2. Development of urban form in Isfahan during centuries (matched on the contemporary streets map) (source: Pakzad (2011)).

Figure 3. Examples of using geometry in art and architecture (source: Stierlin, 2011).

The concept of unity in art and architecture has resulted from Sufism spiritual thinking, where the unity of one (God) and his beloved is celebrated and plural details all mirror the one. The relationship between detail and totality is considered as an Iranian urbanism branch related to unity and pluralism issue; every element and form is comprehensive, individually and combined. While market stalls are independent and complete structured in a combination they create the totality of bazaar (Shakiba, 2013; Tavassoli, 1992; Ardalan, 1973). Order is synonym of geometry in Iranian architecture. Mathematics and geometry played a deterministic role in visual arts and architecture besides organic and natural structures geometrical patterns. Symmetry is a powerful tendency in Iranian architecture at the time. There is a difference between organic expansion and Euclidean geometry but it is similar to fractal geometry, while in static buildings an independent, individual and geometrical order is seen. Even in bazaar, although the pathway creates an organic spiral form without classic geometry in total arcades, architectural modules and nodal junctions offer the sense of geometry and continuity.

Moreover, caravanserais, schools, inns and bathrooms are the extensions of bazaar and all follow strong order and geometries. They present static and independent well-defined geometrical order like leaves on stems (Shakiba, 2013; Tavassoli, 1992; Ardalan, 1973). Figure 4 shows this.

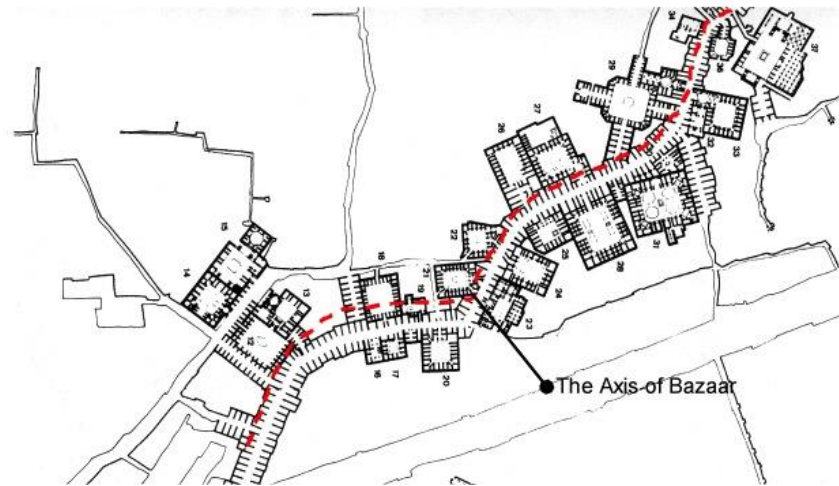

Figure 4. Details of Isfahan Bazaar (source: Ardalan & Bakhtiar (1973)).

Importantly also, the mystical epistemology of Iranian art and architecture was mirrored in Safavid era by Shah Abbas the Great (16 AD) ambitions, exceptional capacity and artistic sense, and was aided by the wealth, security and strong central government that his able government had fostered. Therefore, not surprisingly, the Shah is treated as the world ruler and the rules' palace is at the centre of the world. The palace precincts represent the spiritual head, while the mosque is the symbolic heart of the city's body. At this time a new period in Persian architecture emerges where in rich, sensationally coloured and imaginative details developed by his predecessors become unified into meaningful ensembles of immense scale and grandeur (Pope, 1965) and was later referred to as Isfahan School of thought. Divine school of Isfahan flourished in philosophy and theosophy which eventually influenced architecture, urban design and other arts. It resulted in formation of patterns which determined not only architectural and urban forms in Isfahan city but also served as a model for urban development throughout Iran and the neighbouring countries and cities as it was in Samarkand. The period is known as the period of unity in formal language of urban design. This language is known as Isfahan school of urban design.

Innovative but Integrating Urban Structure in Isfahan

When Isfahan had become the capital of Safavid dynasty it was already well developed and quite prominent on the map of the medieval cities of Asia. The morphology of Isfahan developed organically over centuries. However, the early Safavid (400 years ago) refashioning of the city as their capital was not shaped by the same gradual integration of the new urban elements into the old fabric of the city as were, for example, Istanbul, Madrid, Paris, and London. Isfahan fundamentally transformed at this time through large scale pre-designed urban expansions which granted the principal patterns for its later developments up to this time (Babaie, 2008). It was, indeed, under the Safavids that Isfahan was transformed into one of the greatest capitals in the world of that time.

The new transformations happened in the south of the old city, extending the city towards the Zayande-Rud River. The structure of the city in this period was based on bazaar and a large organic square, called Meydan-e-Kohne (the Old Meydan) and the grand mosque nearby. This

organically shaped meydan was located where the major roads converged in the centre of the city (Browne 1976b). The main routes leading from outside to inside of the city transform into to the major branches of the bazaar, a pattern which has preserved its major characteristics until now. This urban expansion (took place two centuries before the famous Housman's works in the 19th century's Paris) included a large geometric urban space at the south-end of the bazaar, a counterpoint for the Old Meydan. The new urban space or Naqsh-e Jahan Meydan was a joint for connecting the older parts of the city to the new extensions of Isfahan. Its surrounding buildings were erected for the Royal functions, e.g. new palace and royal mosque. Naqsh-e-Jahan was also connected to a wide park-way style boulevard, Chahar-Bagh Street that means Four-Gardens in Persian. Stretching from north to south Chahar-Bagh was established as one of the main axes for the city extension program and connected other royal palaces (Hezar Jarib) on the other side of the Zayande-Rud to the old city. This pre-designed geometric urban expansion resembles contemporary urban development projects. As Ardalan and Bakhtiar (1979) highlight, Shah Abbas the Great achieved his ambitious plans for Isfahan by appropriating an innovative relationship between the new and old parts of the city. This relationship was manifested particularly in the Linear bazaar system (Sarraf, 2010). Figure 5 shows the Isfahan expansion and its connectivity to the older organic parts of the city.

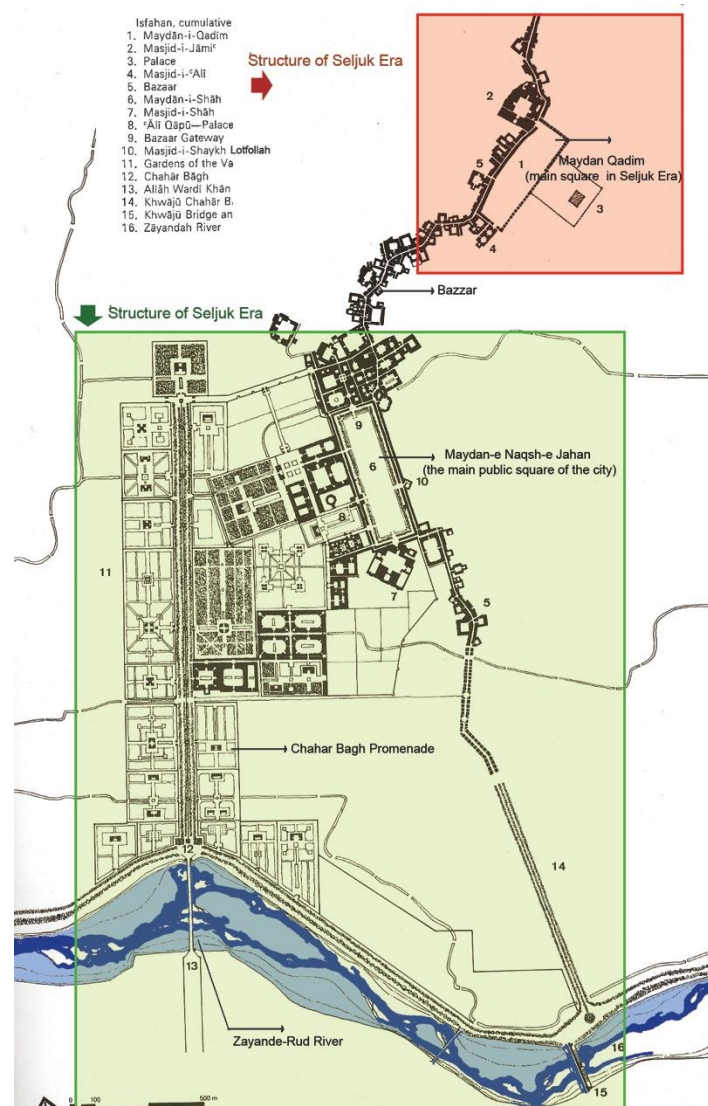

Figure 5. Pre-planned urban expansions in Isfahan (source: Habibi, 2008).

Isfahan urban structure and main elements

According to Piaget (1971) urban structure is a complex of places and streets interconnected. It joins the whole of city and unites all of the city's main components. Traditionally, bazaar was in the basis of the spiral structure of Iranian cities and of what is called Islamic cities. However, the great urban transformation of Isfahan gave rise to and emphasised other significant elements in the urban structure and morphology of Isfahan. Figure 6 presents the Isfahan city after the great urban expansion.

Figure 6. Isfahan after urban expansion (source: Sarraf, 2010).

While the urban form consistent of different elements comprises a unified totality, it is still possible to discuss its components separately. The following four elements of the urban structure that together can be identified as the “central design structure” of a city and present the

city's identity. These include: bazaar, Naqsh-e Jahan (the main public Meydan-plaza- of the city), Chahar-Bagh Boulevard, and Zayande-Rud River.

They hold the city structure together over centuries and preserve areas that are now recognized as the World Heritage Sites:

Naghsh-Jahan: According to Hillenbrand (1999, p. 230) a prominent art historian, the expansion of Isfahan masterplan for its expansion almost 400 years ago is one of the most ambitious and novel schemes of town planning in Islamic history. One of the greatest monuments that came out of it is the great central meydan, Naghsh-e Jahan, which, with its measurements of 512 * 159 m (1680 * 523 ft), is perhaps the largest plaza in the world. The great central meydan was designed as the heart of the new city and served as a stage for military manoeuvres, public processions and games, especially polo. . It is surrounded by two story arcades which focus on the recessed portal of Masjid-e-Shah (Royal Mosque). Opposite at the north end of the meydan, is the royal caravanserai and the bazaar. At the middle of the west side is Alighapu- the government seat and the private oratory of Shah Abbas, the mosque of Sheikh Lutfollaah. Each side of the Naghsh-e Jahan is defined by a certain function and architectural dominance of the building. The northern side shapes the entrance of the bazaar, linking it with the older parts. The royal palace overlooking the Meydan sits at another side and is connected with the Chahar-Bagh Boulevard through its gardens. The fourth side is identified by another mosque-the Shah Mosque (Masjed-e Shah) which is the new grand Mosque of the city (Pope, 1965).

Moving the Friday mosque from the older part of Isfahan to the site of its urban expansion is an evidence of the Shah Abbas's decision to move the city life to the new planned areas. In fact, a Friday mosque is celebrated as the most important building in the Islamic cities. Any decision or proposed suggestion about the design and structure of this building should be made by the caliph, king or the delegated powers (Sarraf, 2010).

Interestingly, the Naghsh-e-Jahan meydan itself is also known as a positive space. The large size facades of the meydan are divided by the two story arcades, which size is proportionate to the commercial architectural modules in the Isfahan bazaar. The meydan is conveying the sense of place through the surrounding architectural monuments with each one being an architectural masterpiece of Iranian art and architecture. For example, as Pope (1965) describes the Masjid Sheikh Lutf Allaah as a culmination of a thousand of years of mosque building in Persia and refers to the whole mosque as of majestic proportions. The Naghsh-e-Jahan meydan becomes an urban courtyard that connects prominent functions and city life together. It is a designed place of integration between the old and new, the organic and geometric, and finally, between delicate smaller scale and large scale architectural elements in an urban scene. It is a designed public place and a meeting point of religion, power and commerce. Figure 7 shows a facade of the Naghsh-Jahan meydan with an overview to the Masjid Sheikh Lutf Allaah.

Figure 7. Naghsh-e-Jahan meydan, source: Silk Cities archive.

Bazaar: Despite the sudden expansion of the city, the Isfahan bazaar was kept as the main urban structures for the new visionary city. Isfahan bazaar remains one of the best examples of the Eastern bazaars, in terms of character, size and architecture. The high levels of spatial integration extend from the Old meydan through different branches of the bazaar and reach the gates. The main thoroughfares shape, at the same time, residential quarters around them are joined by some secondary routes (Karimi, 2003). Isfahan bazaar also underpins the material and spiritual aspects of the city; it does not make distinctions between the urban quarters, and forms an integrated and unified complex with links to the different areas of the city. When Isfahan reached the peak of its prosperity in the Safavid era, the bazaar connected the old and new cities and ensured the survival and well-being of the city. Bazaars are never static because cities continue to live and grow around their significant axes and they offer unique scientific values so that anyone can find the city's identity through it (Pourjafar, 2014).

Ardalan and Bakhtiar (1979, p. 97) describe the bazaar of Isfahan as a strong movement under the shade that stretches from the Khawju Bridge on the southeast to the northern gateway, encompassing, in its course, the primary commercial, religious, and governmental activities of the city." All the different senses of hierarchy, unity, concentration, privacy and publicity, solitude and togetherness, mobility and immobility, connection and proportion, simplicity and complexity, and dimension and domain are implied in the complex of the bazaar and its public spaces. According to them, the bazaar is the primary movement system in the fabric of the city, while the residential pathways are the secondary and the Madi are the tertiary one. Pedestrian crossings are like ribs feeding into the backbone of the city and the vital organs are placed in close proximity to each other; the schools, the baths houses, the granaries, the bakeries; tea houses and stores of craftsmen and of merchants (Shea, 1995).

Chahar-Bagh: Chahar-Bagh Boulevard or as its Persian name means "Four-Gardens", refers to a popular garden typology consisting of four plots divided by waterways or paths forming a cruciform plan. The original public boulevard is 1,650 meters long and consists of four quadripartite gardens arranged along a north-south axis that slopes towards the south. Each quadripartite unit is composed of two square and two rectangular plots separated by pathways and is located slightly lower than the preceding unit. Together, they are experienced as a single boulevard with a central promenade flanked by axial garden plots. The gardens have since been converted into roadways, with plane trees lining either side. Running along the centre of the promenade was a water channel with cascades; the promenade now only features circular flower beds and light posts (Blake, 1999; Blunt, 1966; Ope, 1977; Katouzian, 1986; Alemi, 1986). Water channel also contributes to creating a natural axis that directed further urban development towards the south of the city.

Zayandeh Rud: The Zayandeh Rud River was considered as a natural southern border of Isfahan; a natural element that directed the urban expansion during Safavid (Pourmoghaddas, 2006). Access to the south point of this river was provided with several bridges over it that were constructed at different times. Although the river has always served as a sustainable water source, being located outside the city it never influenced the socio-spatial relationship of Isfahan to a large extent. However, during the Safavids era the Zayandeh Rud River and its bridges played an important role for channelling commercial activities all over the city. Celebrations were also conducted on the Zayandeh Rud River bank (Agha Ebrahimi Samani, 2012). The river is on the main elements for creating natural axis in the city. This "combined natural axis" is the main element that has led the urban growth of Isfahan during its past four centuries. This axis consists of Naqsh-e- Jahan, Chahar-Bagh Promenade, Si-o-se-pol Bridge, and Chahar-Bagh Bala - which is the contemporary extension of the historic Chahar-Bagh towards the south of Isfahan. This axis connects the Zayande-Rud River to the city life with the nature and nature and it ends in the agricultural fields beautifully (Habibi, 2008).

Encountering Modernisation

Since the 20th century, the new universal ideals shaped by the unfolding free market economy, advanced technology and a nuclear family model at the micro-level have prompted the

relationship between architecture and modernisation (Ricouer cited in Foster, 1982:16). Like anywhere in the world, desires for having modern cities have negatively affected historic cities across the Middle East and Central Asia region. For example, following fashionable mindset of becoming modern at the time (1925 onward) Pahlavi dynasty did not pay attention to the existing urban structure and form. While Safavid ambitious plans for Isfahan included urban expansion in the continuity with existing urban structure and morphology, the period of modernisation cut through traditional urban fabric and changed the existing physical patterns and relevant socio-spatial relationship. As Sarraf (2010) points out, although the Safavid urban transformation is considered as a successful large-scale urban development initiative in the history of Isfahan, there are strong criticisms about the urban renewal programs implemented in 20th century, in Pahlavi's era in attempt to modernise Isfahan. The urban growth of Isfahan, akin to many historic cities, was the outcome of a centuries long process. The modernisation programmes of Reza Shah (1925-1941) gave the city a modern-looking face . Radical modernism entailed more than urban expansion but also imposition of automobile as the principal mean of transportation throughout the city and, hence, the cure for all the ills of the compact, integrated urban fabric. Straight streets cut the compact, integrated fabric of the Isfahan bazaar next to the Friday Mosque, as it was the case in many other cities in Iran in the 1930s-70s. Easy access by car to the city centre as its commercial/cultural heart became prominent with automobiles being prioritised over pedestrians. Figure 8 shows how the urban fabric and Isfahan bazaar was cut in order to provide transport solution for automobile accessibility.

Figure 8. Cutting established urban structures to allow cars enter the commercial heart of the city (source: Sarraf, 2010).

Another example is Samarkand; during Russian and Soviet presence in Samarkand most of the significant urban forms were destroyed or/and transformed for different uses. The rest of city was re-planned by the soviet architects using the same model as in other Eastern European towns and given none consideration to the concepts that shaped the city's archetypal forms.

Wide roads were built with long vistas cut through the fabric of the traditional courtyard housing, and raptured of a traditional concept of settlement. Traditional urban neighbourhoods (Mahalleh) were retreated from the principle avenues along which Soviet style apartment blocks and administrative buildings occupied the cleared, open space. Multi storied apartment blocks, hitherto unknown here before, supplanted the traditional courtyard houses and became Samarkand's predominant building types transforming certain parts of the city (Oosterman, 2009).

Moreover, the superimposition of a pattern of straight streets onto many of the historic cities was not only cutting the physical structure it violated the socio-spatial order which were implanted in those urban structures over centuries of incremental growth. For example the commercial connections in bazaar and the traditional residential neighbourhood patterns (Mahalleh), which used to fill the urban fabric in the continuity with the main urban structure and the holistic urban form. The first masterplan for Isfahan envisioned an imposed Cartesian grid network of roads throughout the city. Fortunately the plan was never implemented and some historic parts of Isfahan, e.g. Naghsh-e Jahan meydan were preserved as the World Heritage site. However, as Sarraf (2010) highlights, today's urban development programmes are deeply rooted in the urban renewal strategies of the 1930s that consider the physical form of cities apart from their social aspects.

Conclusion

Traditionally the built environment in the Middle East and Central Asia grew from people's dedication to Islamic thoughts and actions. Isfahan city is an exemplary case of the Isfahan school of thought Iranian Art and architecture that is rooted in the spiritual philosophy of Sufism and harmony between the physical form of the city and its socio-cultural milieu and expressed through geometric forms, squares, circles, domes and four-iwans courts. The Safavid era provided support, prosperity and security for Iranian art and architecture and serve ambitious urban expansions. Thus, Isfahan can be seen as an avant-garde case of urban development for its time that generated values and lessons relevant for the contemporary cases. The morphological integration between the pre designed Isfahan urban expansion and its existing organic urban structure makes Isfahan a masterpiece of Islamic urbanism.

The traditional bazaar in Isfahan with its socio-economic and architectural values was an integral part for urban morphology. Furthermore, the Iranian art and architecture, which influenced the Middle East and Central Asia and developed over centuries, served a significant role to create a morphological integration between the old and the new. Architectural harmony and sense of place were created through architectural modality and excellence in monumental buildings in the Naghsh-e Jahan meydan. However, such richness and inherited values in Isfahan school of thought and the city itself was ignored, while encountering modernism that prioritised automobile and cut through parts of the integrated fabric around the bazaar in order to facilitate car accessibility. While the Safavid urban development plans were to complete the existing structures, the modernistic approach tried to impose a new order regardless of what it was in the ground, cutting through socio-spatial morphological patterns of the city.

Given the lessons from Isfahan School of urban design and exemplary case of the Isfahan city itself, the question therefore, is how the future urban morphology as a determinant for socio-spatial relationships of a city can be in harmony with the traditional morphological pattern of a city. This question exists not only for the historic Islamic cities in the Middle East and Central Asia that evolved during many centuries but also for all cities that regardless of their age represent a specific morphological identity.

Discussion about the similarity of the forms of the cities of Porto (Portugal) and Qazvin (Iran)

Mona Jabbari, Rui António Rodrigues Ramos

Department of Civil Engineering of the University of Minho, Portugal.

E-mail: monajabbari@yahoo.com, rui.ramos@civil.uminho.pt.

Abstract. *At present, in major cities, the lack of urban structure cohesion and connectivity promoted by the expansion of street network dominated by cars has increased dramatically. Hence, social life and citizen rights considering anthropocentric and human scale have been put at risk in many cities. “Old Towns” are perceived as urban structures of the past that are revitalized and given new significance in contemporary cities. The geometrical order of the cities structures shape diverse urban tissue and promote the development in several directions. However, the main activities of the cities occur in the places with the most social interactions. In this context, this paper presents an ongoing research that aims to compare the main areas of Porto (Portugal) and Qazvin (Iran), based on growth of the cities around its historic center, i.e. “Old Town”. The urban form of the cities will be analyzed and assessed by a methodology based on street pattern identification. Also will be discussed the urban design and environmental quality. Research findings shows that the main areas of the both cities require new pattern solutions in order to promote connectivity through pedestrian network.*

Key Words: form, structure, pattern, Old Town

Introduction

Cities, like living organisms, are subject to changes and transformations. This condition has demanded the development of suitable and adaptive design solutions that require the full consideration of the spatial continuity of the city, its physical and social peculiarities, user needs, and desire for safe and healthy communities. In addition, architects and designers need to be familiar with the developmental stages of the city, including components that may have disappeared over time. It is therefore necessary to read different segments that constitute the city to reveal its historical, cultural, social, physical and symbolic features.

Yucel (1979) emphasizes that it is necessary to make some abstractions in order to handle the space conceptually and theoretically, addressing architectural theories on this subject in three categories. The first one is the functional approach which means that the realities of economic, cultural, historical, technological, ecological and social practices are sufficiently understood, in order to provide reasonable explanation of the spatial environment. The second involves placing the spatial elements within the principles of morphological elements that constitute the city image. The last refers to linguistic resources, with the idea that architecture creates a language, in order to comprehend the structural logic of the architectural space. This enables practices intended for spatial typology and urban morphology.

This study mainly focuses on the comparison between two cities in the 16th century. It is possible to describe different urban patterns and forms in many ways. Qualitative methods, as one of methods which describes different urban patterns and forms, include morphological and morphographic description (Conzen, 1988; Whitehand, ed., 2007; Gordon, 1984; Larkham and Jones, 1995). The structure of each city includes a set of paths and nodes, the overall structure of the city and its main activities. The network includes some places that the majority of people are in these places, and Sub-networks are connected by association or joint. The main purpose of this paper is to introduce the skeletal difference and provides the city's guidelines. In this context, it is essential to understand the different models in historical periods. This research studies on various forms of structure which can improve urban structure for pedestrian network.

Without any doubts, such investigations have a significant impact on structural integrity, restoration of social roles and activities in city.

Structure

Cities need the design and plan for social cohesion and cultural diversity. A complete understanding of social, economic, political and cultural characteristics of the city is needed for a successful plan. Finally they will be integrated into the daily life. Viewing economic opportunities in conjunction with other forms of political, social and cultural rights in societies is what builds capable social capital in cities. Therefore achieving the aims of inclusive cities requires an in-depth review of system, structure with the objective of changing the basis of individual engagement with others (UN-DESA, 2010: 15).

Structure as a main bond in urban tissue contributes by major public spaces linkages and has the most dynamism of public space. “Old towns” are perceived as urban structures of the past that are revitalized and given new significance in contemporary cities (Nyseth, T., Sognnaes, J., 2012). The geometrical order of structure builds urban tissue and development direction. The main activities of the cities occur in the places with the most social interactions.

A city is an organism that needs an underlying structure, such as a backbone, to secure its different elements around itself and enable their natural and logical development.

Change in the urban structure of Porto

Teixeria (2008b) focused on form of cities with Portuguese origins. He believed that morphologic of Portugal was divided into three parts. The first consists of the morphological characterization of the Portuguese of street system that include plan hierarchy, the main urban elements, the structure of urban blocks and plots, urban squares and the planning process. The second presents demonstrating how its form synthesizes Portuguese town planning of the sixteenth century. Lastly, the third part analyses the plan for the reconstruction of downtown Lisbon (Olivier, 2011). Between 15-16 century, Portugal had innovation of planning in urban network where central area of city is. It had composed of set blocks organized on a regular structure. This network had used cathedral and new tissues shall be a regular planned urban space (Bettencourt, 2007).

Important feature of previous study was the identification of the most important node of the overall city structure. The Porto Metropolitan Area is characterized by a coastal Atlantic landscape. The urban pattern is concentrated among the main nuclei (Porto and Vila Nova de Gaia) and scattered among many small rural towns and villages. Products, like Porto Wine, produced in the Douro valley, was already in the 13th century transported to Porto in Barcos Rabelos, add such identity to the city that is still known for them, even though Porto Wine is actually produced in Vila Nova de Gaia. However, what is really important it to understand the dynamics of the city and its evolution until times. The downtown of Porto can be defined by certain main landmarks – it is centred in Avenida dos Aliados (Silva, 2008: 63).

Porto is one of the oldest European cities. Archaeological research conducted in the Cathedral area reveal that the first traces of civilization in the space now occupied by the city of Porto dating from the late Bronze Age (3000/4000 BC). The city had its start on the hill of Penaventosa (Currently Morro da Sé), time was a good strategic advantage as it allowed good visibility on the estuary of the Douro, and was otherwise difficult to access and presented favorable topographical conditions the deployment of buildings. The hill encircled by a wall, known as Old Fence or Fence Romanesque (Cabeças, 2003 & Wikipedia, 2013).

Hugo awarded the first charter city residents (the Porto town) (Cabeças, 2003). The Porto of the 12th century was an episcopal town (with its unique cathedral parish), namely, the bishops were the owners of the town, with the right to apply justice, administer the lands and collect

taxes. During this 3-year period there was a tension between D. Hugo and the inhabitants of the Borough, which later lead to conflicts between the population and the bishops this century. For this reason, began the construction of the Cathedral by Bishop Hugo, it was an Old Fence important element, which affected the structure of the urban tissues of the town. Inside the building was filling the free spaces. The lack of space to build the interior led to the need to build enough away from the wall, creating needs for planning and advocacy. During the thirteenth and fourteenth centuries continued a period of expansion in the Port grew out of the old fence, around the Cathedral, and in the lower zone of the Ribeira, connected by an urban network that was High Density (Cabeças, 2003 & Wikipedia, 2013)

In the fourteenth century the port grew along the bank of the river Douro, reflecting the importance of trade and maritime activities. In that same century, during the reign of D. Pedro, began to be built a new outer wall that was completed in 1376, the New Fence or Wall Fernandina, covering an area of about 900,000 m² and being completed in the reign of King Fernando (Azevedo, 2010:41).

The picture shows process change central city of Porto. It has been shaped in different periods of the history between 12th century and 16th century. In the center of structure, there is the open space which has been created mainly for the religious activities. During time, the ministerial activity was formed. This picture illustrates the structural changes of the city during three periods (Figure1).

Figure 1. Analysis of Main Structure: Organization of the Territory in the Middle Ages (A - Wall of Bishop Hugo the Twelfth Century; B - Fernandina Wall the Fourteenth Century)(source: Azevedo, 2010:41).

Change in the urban structure of Qazvin

The expansion of city has depended on development the cities' spatial structure and commerce structure, while commerce tends to concentrate in agglomerations. Commerce is one of the most important functions of a city. A crucial idea states that the structure of traditional cities in Iran is based on its bazaar's economic and political factors. From early Iranian urbanization to the present time, different factors have been influenced in the formation of traditional cities. This composition has had its own form in each period, and the governors complete this combination to show their strength and understanding. Some scholars believe that bazaars are the main core of Islamic cities; others consider the "Jame mosque" as the city center; whereas some believe both are Islamic city concepts (Encyclopedia Islamica, 2012).

The structure of Iranian traditional cities reveals that a bazaar, which usually takes a linear shape, acts as the spinal column of the city and continues toward the main gates of the town (Assari et al., 2012). A bazaar is thus located in the main core of Islamic and Iranian cities. An Iranian city is frequently defined by a congregational Jame mosque and must have a chief

bazaar nearby. For economic and commercial activities in Iranian cities, the bazaar is the most important public space that has been used for development of city (Pourjafar, 2014).

The collection of the economic, social, religious, and main cultural centers of the traditional Iranian city is called a “bazaar”, which is unique to Iran. The bazaars of old Iranian cities were fully prepared to accept much flexibility in terms of space and functionality. Bazaars are generally connected to the city gates through the main urban network. Residential neighborhoods are located in the spaces between the gates of the city and the bazaars. The bazaar complex is like the backbone rooted in the organic context of the city. Thus, In Iranian cities, the bazaar are connected to living space. One guarantees the other one, promotes its mobility. Bazaars in Iranian cities are the main artery of the urban life system and represent the center of social and economic activities. Bazaars provide cohesion among the different parts of cities, such as residential areas, as well as socio-political and trade centers. Bazaars as a unifying element connect the main urban functions and guarantee the city's economic and social life (Pourjafar, 2014). The cities have had some of the richest economic and cultural resources that influenced its underlying urban tissue. Cities were built on a pedestrian scale (Figure 2).

Figure 2. Bazaar in the Past and the Present.

Qazvin is one of the largest cities and capital of the Province of Qazvin in Iran (Wikipedia, 2013). Qazvin central position in Iran also preconditioned it to become the capital in the Safavid (1524–1576) period. It is a provincial capital today that has been an important cultural center throughout history. Archeological findings in the Qazvin plain reveal urban agricultural settlements for at least nine millennia. Qazvin geographically connects Tehran, Isfahan, and the Persian Gulf to the Caspian seacoast and Asia Minor. Hence it is a strategic location throughout the ages. Given the geographical position of Qazvin at the center of the Iranian plateau, it has been known as one of the most important trade centers of Iran. This position occasionally makes it the bridge between the East, West, South, and North. Its bazaar has developed in the parts of the city that are closely connected with producers and customers.

Before becoming the era capital, the main element of the city of Qazvin was a small bazaar located in the Southern part. In early Islam, the core or backbone of the city (along the East-West axis) was the Silk Road that ran through the middle of the city. The “Jame mosque” formed within this core and the bazaar, as a strictly linear element, extended from two sides of the core and along the main axis. During the Safavid period, the king decided to move his court away from the old city. He set up chogan square as the central core of his plan in the north margin of the city, and tied the old core at chogan square with Boulevard (Sepah Street) that extended the city along this axis. With the connection of the new bazaar around the chogan square and the old bazaar alongside the square, the invigorated socio-economic life of the city continued. In the next period, residential neighborhoods formed around the bazaar that became the heart and spirit of the town (Jabbari, 2007). This picture shows the structural changes of the city during three periods (Figure.3).

Figure 3. Analysis of Main Structure: Before Becoming the Era Capital and In the Safavid 16M.

Compare to two structure

The main structure of Porto is the nuclear. The nuclear structure is strong articulation and there is an intriguing connection between constituents of the nuclear and street. This structure provides further impetus to form other part of tissues and a pattern for future of Porto city. This pattern is based on open space that urban tissues formed around it organically. It can help pedestrian to find destination and finally it is suitable structure for social Interaction.

On the other hand the main structure of Qazvin is the linear. This is a path-dependent structure in which the initial shapes of cities have expanded. Linear structure influences on urbanized nodes to develop along the urban network. This pattern joins nodes in urban tissues. Overall, Qazvin bazaar had main pattern that use for development of urban tissues (Figure 4).

Figure 4. Analysis of Main Structure Qazvin and Porto.

Current Situation of Porto Structure

The preparation of the new municipal master plan for Porto started in 2001 and the plan was approved by the last executive in 2005. The strategic objectives of the plan are: the strengthening of the urban identity of Porto, the rehabilitation of the public space and of the built environment, the rationalization of the transportation systems, the reduction of the existing urban imbalances, and the promotion of the historic quarters and of the central area (Pinho & Oliveira, 2004). Considering to the existing potential, there is no cohesion structure in city center of Porto up to now. Active spaces do not have connectivity for pedestrian way. For example Santa Catarina Street and Cedofeita Street are separated from city center. The modernist work was the construction of radius streets beside city center. Afterwards, new plaid streets penetrated through the old organic urban tissue and divided its cohesive urban tissue into separated parts. Therefore, there was not coherence between the old and middle urban tissue of the city. In the next periods of the city formation, this coherence faded gradually. Developing city increase caused a functional-spatial disorder and gap in Porto and its historical center. Table 1 and Figure.5 shows features of structure at the present and previous.

Figure 5. Porto in the Fourteenth Century

3	Access	Hierarchy	Without Hierarchy

Current Situation of Qazvin Structure

Qazvin in the past has a linear- nuclear structure. The structure nodes are the market, Mosque and the Safavid gardens, as articulations. They have been used in various scales of city for converting and connecting activities. With the beginning of modern urbanism, the functions and importance of the movement was through riding instead of walking in the city. Using the cars damaged human scale and visual space decreased in the city. New business in Khayyam St. formed a direction from north to south and the traditional market has faded during time. Green Plaza in the center of the main nodes of activity and socio - cultural city changed to traffic node in the city. Hence pedestrian local importance has been greatly weakened. Table 2 shows the

comparison between pre and post-modern era making changes in the anatomy of the eye focuses on different aspects of being. Figure 6 illustrations features of structure at the present and previous.

The New Pattern for Network Pedestrian

Roads and nodes are one of the fundamental components of the physical structure of cities. In addition these elements effect on the perception and image of citizens. Nodes and streets appear in the minds of city residents like lines, which permit the connection in different areas of the city. They are always place the incidence of various events such as green space, trade, cultural exchanges, conduct religious ceremonies, etc. Thus they play an important role in social development, and responsible for cultural city.

Some roads and nodes act as the main structure, which major collective activities in the city are done in these areas. In modern cities with provided the roadway, the role of social and human scale of the street and the field are weakened. With enhanced pedestrian-oriented, skeletal elements can be converted, to the places which people have mental relaxation, and increase shelf space with putting options with the various activities with such an approach to urban restructuring and strengthening the articulations that link the urban citizens with civic life. Urban places and spaces can be expected that the quality and richness of improved physical, functional space and return them. Analysis carried out shows the link between old and new urban structure, physical integrity and urban tissue repair in structure town centers is essential for meaningful and strong articulations (Plut, 2008 & Peters, 2010).

This research studied stages of growing traditional city in past period that it is based on pattern of pedestrian movement and then showed current situation. In this part did not seen any unic in urban tissue. The new measures seem to work as well as the standard syntactic measures in modeling the manner in which the network affects pedestrian flows. The new pattern used in

this paper are inherently that there are important in determining how likely it is that a given space will attract greater flows of movement as compared to its surroundings. in historic center of town can be considered special in articulations, with special attention to their role, improved functional structure - Space City can be facilitated. Then other element join main way, which has a linear structure, with Development commercial activities in the main centers of activity are connected to each other. The articulation is a green plaza or open space, converter functions as a space for recreation and leisure, fill the gaps between the urban centers has been dispersed. Figure.7 shows features of structure .This pattern has specific tasks to fulfill:

1. To produce a map based on tradition pattern belong to the walking and biking routes;
2. Cooperation, motivation and networking of local businesses and other actors, such a property owners and property managers to improve the quality of the environment;
3. To enhance the interaction between the new and old urban tissues and to create new ways how the residents can participate in shaping up their own living environment;
4. To produce concrete development ideas for the two important walking and cycling routes in the area;

Figure 7. The New Pattern for Network Pedestrian.

Conclusion

This paper tries to provide a clear view of the development of spatial structures. This research intends to find the pattern of structures in two different cities. Traditional structure has been assessed by the distribution of internal characteristics of cities, such as Bazaar or Open space. Nowadays, Advances in transportation change the life styles of people and affect city structure. Based on the comparing results between the linear structure of Qazvin and nuclear structure of Porto, it can be possible to introduce old and mixed patterns in the future researches for improvement of nowadays cities. These new patterns can be helpful to make a connection between different urban tissues while keeping a coherent structure for the city by pedestrian network.

Finally, one of the main results was the pattern network for pedestrian showing the role of nodes and lines services available and the best of cycling and walking routes in the area. The urban and historic framework of the city center has thus been reconfigured into a pedestrian square capable of hosting cultural events and public meetings. New services have already developed within the area including art galleries, souvenir shops and cafes.

Open spaces and the new Brazilian urban form

Open space systems and the constitution of the contemporary Brazilian urban form: first results

Eugenio Fernandes Queiroga, Silvio Soares Macedo
FAUUSP, QUAPÁ, Rua do Lago 876, São Paulo, Brazil 04280-000.
E-mail: queiroga@usp.br.

Abstract. *This paper has the aim of showing the activities and first results of the research project called “Open space systems in the constitution of the contemporary urban form in Brazil: production and appropriation – QUAPÁ-SEL II” under development since 2011 in the Laboratory QUAPÁ – Brazilian Landscape Panorama of FAUUSP Project department, project of national coverage that is developed in a partnership among twenty Brazilian research centers.*

Key Words: open spaces, system, urban form, urban morphology

Introduction

The second half of the 20th century was marked by a significant urban growth, with radical changes in urbanistic-landscaping attitudes, modernization of the Brazilian city, with the consolidation of the automotive vehicle as the main locomotion and cargo transportation mean, with the urban population growth, with the popularization of gated communities – developments and condominiums, and with the cloistering of the urban plot within walls, with the creation of park networks, with the relative popularization of bike routes, with the spreading, fragmentation and dispersion of the urban area in the most different parts of the country. In regard to environmental issues, the ecological bias was introduced both in politics and in legislations, and also in urban designs, with the creation in the late 1980's of the law of the Urban APPs – Urban Permanent Protection Areas, intended to protect remaining native vegetation and to replant it along water courses.

Figure 1. Allotment closed in Palhoça, Metropolitan Region of Florianópolis – SC (Southern Region). Source: Lab-QUAPÁ, September 2011.

The early 21st century shows a consolidation of all those processes, and the appearance of a city that is very different from the one existent in the 1950's and 1960's. The Brazilian contemporary city is very constructed, much more than expected, horizontal constructions, residences, shops and small buildings, occupying nearly all its blocks, part of the squares is not installed or is poorly maintained, many of them are occupied by schools, daycare centers, health centers, slums, etc., and the streets have sidewalks which are sometimes narrow, poorly maintained, with or without trees, and which are actually not comfortable for the circulation of pedestrians.

Figure 2. Housing program of the federal government, Maceió-AL (Northeast Region). Source: Lab-QUAPÁ, May 2014.

On the other hand, the urbanistic legislation is obtaining “good” results in large urban areas, controlling verticalization, with the appearance of intra-block open spaces, with the delimitation of areas for the creation of social interest dwellings, with a more attentive view on the mobility conditions of physically challenged people, with the destination of stock areas for open areas in allotment processes, with the adoption, even though in a shy and poorly done manner, of urban permeability indexes, and with the control of visual pollution (in an experimental way in some cities).

Figure 3. Partial view of Santos-SP (Southeast Region). Source: Lab-QUAPÁ, February 2014.

A research project in progress

In view of such facts, and with the aim of attaining a deeper knowledge of the urban landscape and morphology, with focus on its open spaces, in 2012 the group of researchers of the Laboratory QUAPÁ – Brazilian Landscape Panorama – of USP School of Architecture and Urbanism, associated to a national network of Brazilian researchers, proceeding with the studies started back in 2006 about the open space systems of the contemporary Brazilian city, started a new research project called “Open space systems in the constitution of the contemporary urban form in Brazil: production and appropriation – QUAPÁ SEL II”.

In the research project, there is an attempt to understand the relations among the main stakeholders in the city formation process – conceptions, production in the strict sense, distribution and appropriations. The following is being done:

(1) construction of a methodological referential for the qualitative analysis of relations between the open space systems and the urban form, and between these and the pre-existing ecological structure;

(2) establishment of criteria to appraise such relations;

(3) formulation of systems of variables to guide propositional actions of urban form qualification, taking into consideration its relations with open spaces and its contribution to the public sphere. Thus, subsidizing the formation of inputs for the actions of Public Authorities;

(4) study of principles of dependence between open space systems and constructed structures, creating references about existing morphological models and standards;

(5) establishment of the types of implication between the open space systems and the existing urban form, and the environmental degradation processes in progress, in particular those depending on or occurring because of the inexistence of qualified open spaces;

(6) verification of the role of public and private agents leading to the configuration of the phenomena detected in 1, 4, and 5;

(7) verification of how climatic variables are distributed in the latitudes of the cities under study, and their specific behaviors in response to the dynamics of elements.

As specific objectives of the research, we have:

- to understand the main structures of the urban form and open space systems of the Brazilian city;

- to systematize the urban forms of each studied locality in order to obtain an outlook, and then establishing a criticism of the main set of urban forms of the Brazilian city, to date unknown in their totality, which is key for future actions and studies;

- to establish qualitative analysis method procedures and appraisal criteria of open space systems and urban forms in regard to:

(1) their potential performance for the establishment of the public life;

(2) the degree of obsolescence and vitality of different types of open spaces and constructed forms;

(3) the understanding of routine and symbolic meanings;

(4) their environmental contribution: drainage, microclimate, macroclimate, soil stability, ecological conservation and dynamics (mangroves, dunes, urban forests, savannas, etc.);

(5) the discussion of design alternatives for the existing open spaces and their relations with the pre-existing urban tissues;

- To create specific graphic and iconographic material, which contribute to this study, to be part of the collection of the Laboratory QUAPÁ and of the associated research centers, in order to collaborate in this study, in correlate studies, and to the demands of the public in general.

As case studies, the main Brazilian capitals and some large scale cities were selected, in a total of 36 cities in all the parts of the country. These are: Belém, Belo Horizonte, Brasília, *Campina Grande*, Campinas, Campo, Grande, *Cuiabá*, Curitiba, Florianópolis, Fortaleza, *Goiânia*, *João Pessoa*, *Jundiaí*, *Limeira*, Maceió, Manaus, Maringá, Natal, Palmas, Porto

Alegre, Recife, Ribeirão Preto, Rio Branco, Rio de Janeiro, Salvador, *São Carlos*, São Luís, São Paulo, Santos, Sorocaba, *Teresina*, Uberlândia, *Umuarama* and Vitória.

Therefore, capitals of all Brazilian regions are included, comprising a very representative sample of big Brazilian cities, and also a significant sample of medium scale cities (from one hundred thousand to less than one million residents). To many cities, it is the continuity and deepening of the reading, to others, a new study, because they were not included in the first research project (the above cities written in *Italic*).

The privilege given for capitals allows:

(1) the preferential study of metropolitan realities since the majority of Brazilian metropolises are centered by state capitals;

(2) the investigation of the main models of contemporary urbanization, because the larger scale real estate capital has in the metropolises its main activities, and therein executes the development of new models of undertakings;

(3) the study of more sophisticated (in general) urbanistic and environmental legislations, which frequently serve as model (of questionable adequacy) for smaller size cities;

(4) the analysis of more expressive state public investments in open space systems, because capitals are their preferential locus;

(5) the analysis of municipal investments in the sector;

(6) the study of main private investments in the urban tissue, both of specific programs, "*Minha Casa Minha Vida*" (My House My Life, in free translation), and in the constitution of gated developments and condominiums; in this new stage, a special attention will be paid to the private production, in its various scales, actually the main responsible agent for the constitution of the urban tissue of any given city, and thus of its open space system.

(7) the investigation of federal investments and policies for the housing sector;

(8) a convenient coverage of the national territory, because it allows to appraise different realities, while allowing to create urbanistic and landscaping references.

The selection of medium scale cities, especially the countryside ones, adds to the discussion of metropolises and capitals the issue of diffusion of the main national urban centers urbanistic culture and the specificities of local processes. It also allows the comparison among different processes in medium scale cities, given the differentiated insertion of the selected cities in their respective urban networks, where some are regional centers distant from metropolises, and others are part of expanded metropolitan complexes.

About the activities in progress

The studies were initiated with the definition of conceptual standards to be followed, with the selection of a systemic bias relating producing, regulating and managing agents, with the urban form itself and its users, who are also transforming agents.

Such concepts were confirmed in two national meetings of the network researchers, and in a series of debates of the research group based in São Paulo, which also confirmed the methodological bases of the urban form mapping to be used to represent in two dimensions the form of the Brazilian city.

As support to the knowledge of producing agents, and in order to increase the understanding of producing agents about the urbanistic legislation and legislation regarding the open space systems of each city under study, workshops were conducted in the cities under study, with the support of local partners. Workshops have the following objectives:

- to characterize the open space system in the urban form of the municipality under analysis;
- to understand the role of open spaces in the constitution of the contemporary urban form production;
- to understand the role of the environmental and urbanistic legislation in the production of open spaces and the urban form.

- to understand the concrete role of the agents responsible for the contemporary production of open spaces and constructed spaces in the municipality;
- to discuss reading and critical analysis procedures regarding the research theme;
- to discuss criteria that might subsidize public policies regarding the production and appropriation of open spaces and the urban form at local level.

Workshops were already held in the cities of Uberaba and Uberlândia, in the state of Minas Gerais, Maceió in the state of Alagoas, Santos, Sorocaba, and São Carlos in the state of São Paulo, Vitória, capital of the state of Espírito Santo, and Campina Grande, in the state of Paraíba.

The duration of workshops is three days, and they are carried out in partnership with the local group or with some public entity, which is the case of Santos and Sorocaba. They are structured as follows:

- first day – overflight and field visit by land, with the support of our local partners. This visit and this overflight are fundamental, for a general and comprehensive photographic documentation, as well as for the total understanding of the morphology, road structure and type of open spaces of each city.

- second day – *morning period* – presentation organized by the local group in which specialists related to the university, to the Public Power, and to the society present reflections and summaries of the following topics: open space system, urbanistic and environmental legislation, management and implementation of public spaces, governmental and real estate market investments, and urban form.

- *afternoon period* – division of participants in four work groups, which using the material gathered by the local group and the mapping produced by the São Paulo group analyze the city from four viewpoints/one per group: open space systems, environmental and urbanistic legislation, public and private investments (the role of agents in the production of space), and morphological standards at the urban tissue scale.

- third day – continuity of works and, at the end of the event after the presentation of each group works, a synthesis is made by the workshop participants and by the group of São Paulo about the city form and its open space system, which in general results in a graphic scheme drawn over the maps. From the results obtained, the local group is requested to produce a text deepening and synthesizing what was studied during the workshop.

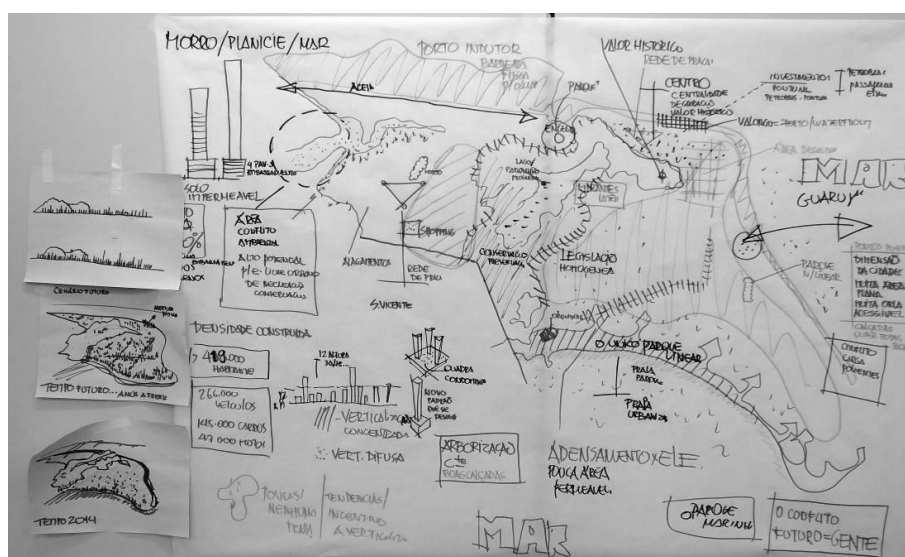

Figure 4. Synthesis map of the workshop in Santos, in which urban expansion vectors, general characteristics of the process, sidewalk schemes, etc., are highlighted. Source: Lab-QUAPÁ, February 2014.

Workshops are scheduled months in advance to ensure the participation of the local group, always related to a public entity or university/in general represented by a research group related to the area of Landscaping or Urbanism, and its components are generally graduate and undergraduate researchers, professors and technicians related to the Public Power, generally the municipal prefecture (local government). When the organization is done by some public entity, such as in Santos, there is a natural predominance of public officials related to the municipal technical staff among its components.

In parallel, we are developing a series of other activities, namely:

- elaboration of thematic maps about the main morphological standards of the Brazilian cities and the characteristics of their open spaces.

Those maps are done by using the bases for ArcGIS and aerial photos. This is an activity in progress, nearly consolidated, and is centered at the laboratory QUAPÁ in São Paulo, in the extent that we have put together a technical support body for such activity, basically constituted of undergraduate students. Mappings already done and in progress are time-consuming, because they are made through visual analysis of Google Earth aerial images and Google Street View images, now available for most of the Brazilian cities, which makes our work much easier. Maps are been elaborated by a group of 11 students/researchers.

This is an extremely time-consuming and careful work, because for each city all its blocks are analyzed, and for each of them numerical values are attributed and correspond to the variables under analysis: tree coverage, distance of the construction from the plot limits, morphological types, and open spaces.

- conduction of annual Seminars internal to the QUAPÁ-SEL National Network for sharing results, enhancements of the method, approximation of different approaches, and formulation of common concepts. In August 2013, our eighth Seminar was held, in the city of Rio de Janeiro, with the support from the Federal University of Rio de Janeiro/PRO-ARQ, and co-organized by Dr. Vera Regina Tangari with the theme “Open spaces and urban form, interpreting characteristics and conflicts”, which gathered more than fifty researchers from our network coming from the whole country, and in August 2014 we will hold our ninth seminar in the city of Vitória, Espírito Santo state.

Furthermore, we have done the following:

- participation in scientific events and conduction of conferences and lectures;
- weekly debates of the São Paulo nucleus, and biweekly debates with the Campinas nucleus;
- bibliographic studies;
- formulation of partial texts that will support the structuring of a final text that we intend to become a book about the research theme, and showing its results.

Preliminary results

In these two years of work, we have the following preliminary results:

- formulation of the theoretical-conceptual panel regarding the current reality of big Brazilian cities, and with higher adherence, evidently, to the cities and metropolises selected for this research – process in progress;

- establishment of the method of analysis of relations between open space systems and the urban form applicable to the national reality – already developed and in natural process of enhancement, through workshops and seminars, with mappings and methodology based discussions;

- constitution of a comprehensive national panel regarding the relations between the current processes of production of open space systems and the urban forms, and the formal standards established in each city resulting from vernacular and market procedures, and also from the existing urbanistic and environmental legislation – this activity starts with the first workshops,

and shall finish with the last of them, when it will be possible to put together a good general panel about all of them, and to check the common and specific points;

- proposition of a criteria system to evaluate the quality of open space systems and urban forms considering their potential for urban life and their environmental performance/formulation of general and specific critics about the subject from analysis parameters that systemically consider the involved variables, thus preventing the formulation of “urban form manuals” – and the first schemes of open space quality evaluation are ready, and shall be enhanced and developed as a text. Preliminarily, we are putting together a support notebook to the workshops, which is now in the final writing stage;

- the strengthening of the QUAPÁ-SEL National Network and of the research procedures that take into consideration the multidisciplinary and interdisciplinary contribution – routine activity, based on workshops, seminars and joint works, being the continuous activity of the research process;

Aspectos morfológicos - Sorocaba

Espaços livres intraquadra

Figure 5. Map of open spaces intra-blocks. Source: Lab-QUAPÁ, April 2014.

- formation and enhancement of researchers in different levels (from scientific initiation to post-doc) – routine activity, attested by the countless students tutored by all the senior researchers of Lab QUAPÁ;
- publication of partial results in scientific magazines of the field, and in scientific events; - the final publication of the book with the disclosure of results – process in progress;
- complementation of the databank of laboratory QUAPÁ – in constant updating process with the inclusion of aerial photos and mappings.

Aspectos morfológicos - Sorocaba

Recuos Intraquadra

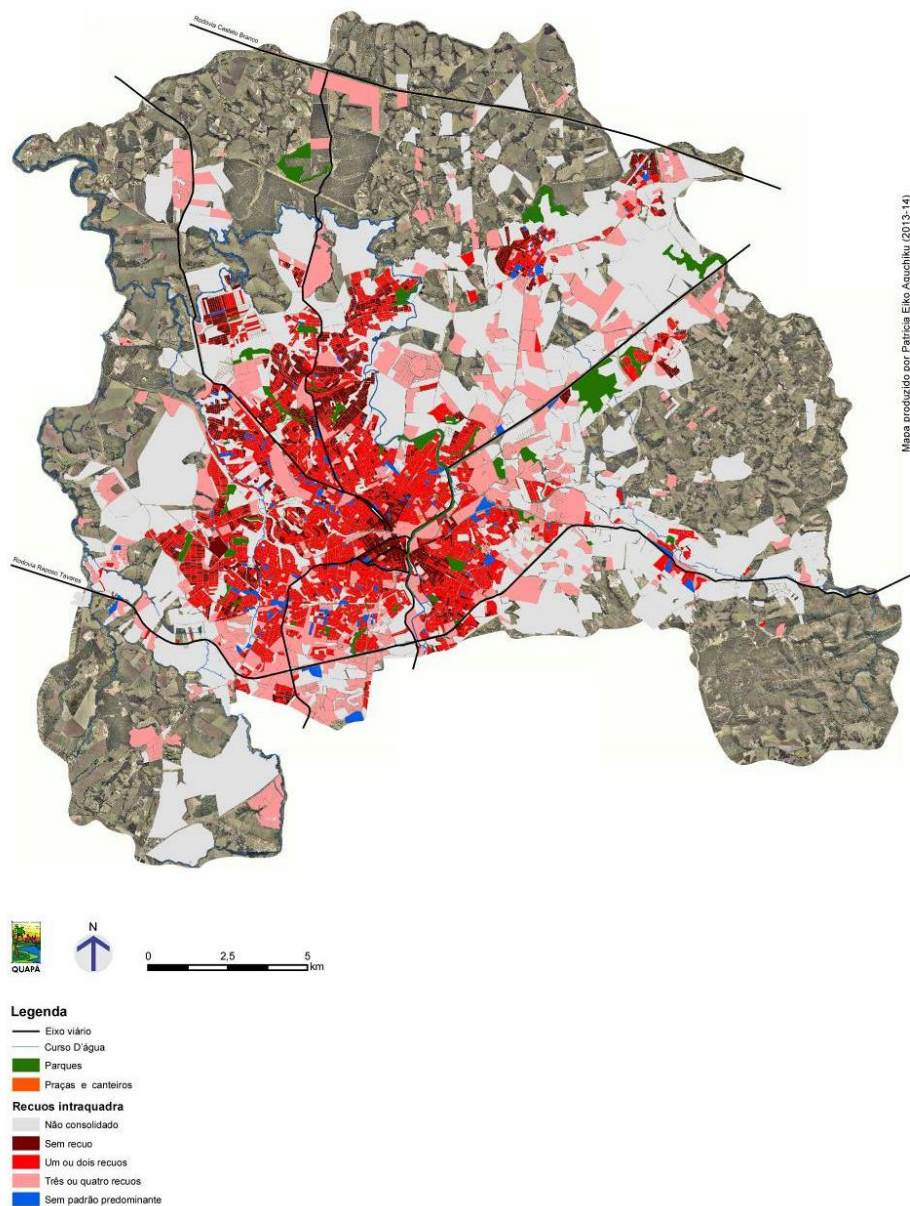

Figure 6. Map of setbacks and clearances. The darker least setbacks between buildings.
Source: Lab-QUAPÁ, April 2014.

- We have the following specific results attained:
- determination of the main morphological types and standards existing in the medium and large scales Brazilian cities;
 - establishment of representation standards of these types and standards;
 - understanding of some of the most important logics distribution of such types, such as the location of gated developments, gated communities, new popular neighborhoods, and shopping malls.
 - location and consolidation actions of Permanent Protection Areas;

Aspectos morfológicos - Sorocaba

Volumetria construída Intraquadra

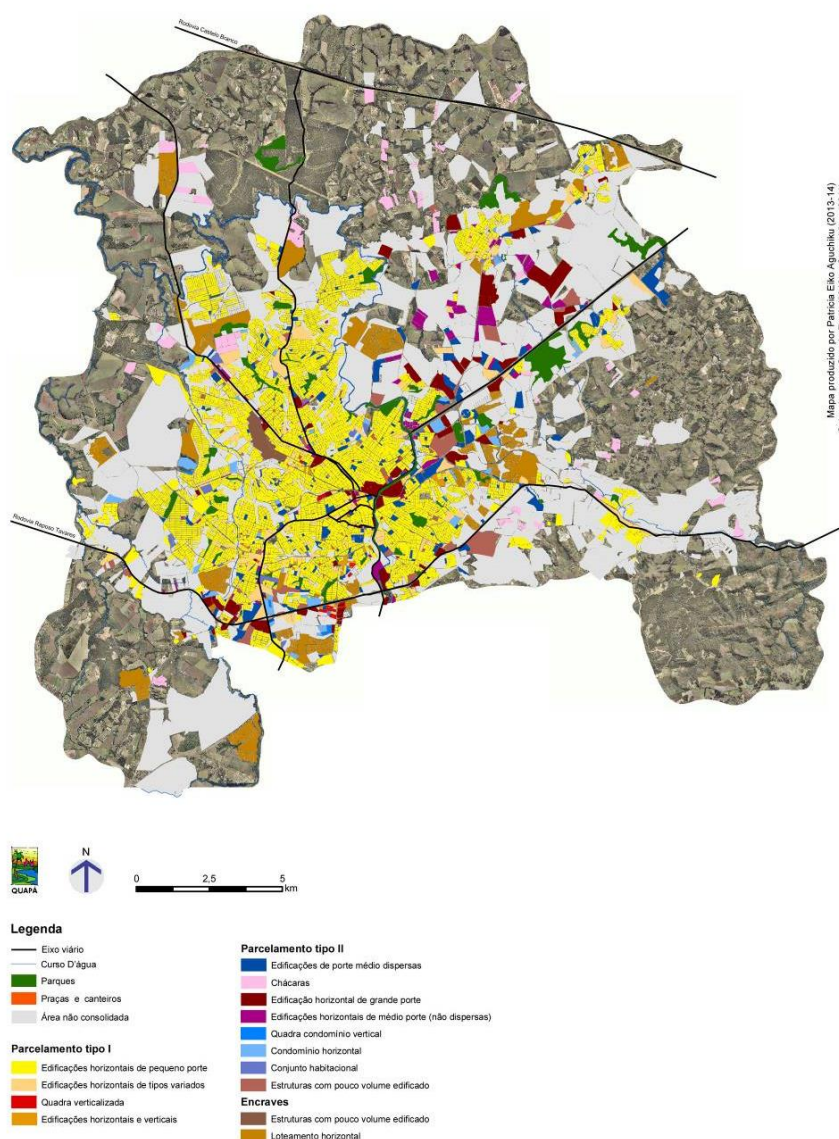

Figure 7. Map of morphological patterns. Source: Lab-QUAPÁ, April 2014.

- understanding of the distribution of verticalized areas and their morphological characteristics.

In short, this is a thorough and time-consuming work, only possible thanks to the collective effort of all the members of the QUAPÁ-SEL Network. At the end, a comprehensive panel of open spaces and urban forms characterizing the contemporariness of important Brazilian cities will be obtained, allowing to contribute with concepts, methods and systems of guidelines that might help the elaboration of public policies aiming to qualify the urban form and the urban open space systems in Brazil.

Abstract. *The research project named “The open spaces systems in the Brazilian urban form constitution: production and appropriation” (2012-2016) held by Faculdade de Arquitetura e Urbanismo da Universidade de São Paulo (FAUUSP) aims to analyze thirty-five cities in order to characterize and diagnose the relationship between open spaces and urban form, by an multidisciplinary approach. Workshops realized in each city are part of the activities. Campina Grande, Uberaba and Uberlândia were the first three: medium cities, with a population varying from 315 thousand up to 645 thousand people, they present similar processes together with important differences. Distinct biophysical environment, social, economic and cultural characteristics generated unique cities in terms of urban form and open spaces distribution, mainly public ones. With good square distribution in historical city centers, recent economic development was not followed by the same accurate care with public spaces. There are parks, intensively used, but concentrated in certain urban zones. The most important real estate initiatives are closed residential areas and tall buildings, mostly for high-income population, and residential areas for low-income people. Therefore, urban legislation does not control the resultant urban form, and does not understand the relation between buildings and open spaces as a systemic one.*

Key Words: open spaces, urban form, morphological patterns, public policies, appropriation

Introduction

The research project named “The open spaces systems in the Brazilian urban form constitution: production and appropriation” since 2012 aims to characterize and diagnose the open spaces of thirty-five cities. The objective is congregate knowledge and efforts in order to understand Brazilian urban tissues patterns and therefore how they interfere in the open space system constitution, as well in the public sphere constitution that take place.

Our proposal is interdisciplinary and multi-institutional gathering together architects, urbanists, landscape architects and geographers from different institutions such as Faculdade de Arquitetura e Urbanismo da Universidade de São Paulo (FAUUSP) and Pontifícia Universidade Católica de Campinas (PUC-Campinas). Establishing and coordinating a Brazilian research network with representatives from each related city, we aim to set up a deeper understanding of Brazil.

We accomplish three-day workshops in every city. On the first day, we execute an aerial overview and a site seeing by car through the most distinguished open spaces, and on the second day, there are lectures with public government representatives, academic members and non-governmental organizations. During the last day, the workshop take place dividing the participants in four thematic discussion groups with presentations and synthesis in the end.

The first group deals with public open spaces and privately owned ones, establishing patterns, mapping, types and functions. The second group identifies the main stakeholders responsible for the urban space production: private and public initiatives, small and medium enterprises (SME). The effort is not only mapping the stakeholders but identifying their actions towards the open spaces production and management in a critical approach, describing the processes and impacts on the urban form, the environmental and ecological dynamics, and the public sphere constitution (daily and political), beyond their relations and conflicts.

The urban and environmental legislation is the third group theme. The relation between open spaces and buildings is shown through graphic simulations, as well as land subdivision, zoning

and land use (Figure 1). Like other groups, the objective is a critical view of urban form considering environmental issues and public appropriation.

Figure 1. Urban legislation and open spaces in Uberlândia. Source: Lab-QUAPÁ, October 2013.

The last group considers the open spaces in the definition of morphological patterns, identifying and analyzing existing urban tissues, as well as creating specific categories. The unity scale for analysis is the block and, as a result, the Lab-QUAPÁ developed thematic maps for each city, considering also geomorphological and hydrological aspects, vegetation, land configuration, road system and land division. The identification of gated compounds, horizontal condominiums, verticalization, informal occupancy among others typologies, reflects recent urban processes.

The analyzed “medium cities”

For this article, we considered three cities: Campina Grande in Paraíba State, in the northeast region, Uberaba and Uberlândia, both in Minas Gerais State in the southeast of Brazil. Their characterization leads to a conceptual discussion²⁸⁹: the definition of medium cities. In Brazil, the urban perimeter of a municipality determines a city, which is an administrative criterion that reveals very few about the urban Brazilian phenomenon, only that there are many cities in number. It is commonly accepted that “medium sized city” is the one that has between 100 thousand and 500 thousand inhabitants. Therefore, Uberaba (315.3 thousand inhabitants in 2013²⁹⁰) and Campina Grande (400 thousand inhabitants in 2013) would be medium sized cities, while Uberlândia exceeds this limit with 646.6 thousand inhabitants in the same year.

“Medium cities” differ from “medium sized” ones: beyond the number of inhabitants, they also have a relevant role in their urban network, performing as a centrality with diversity in circulation and offer of goods and services in an important intermediate level in the net. Campina Grande is the second city in number of inhabitants of Paraíba State (PB), and the center of a metropolitan region composed by fifteen cities. Uberaba has the fourth agricultural GDP in the country and Uberlândia is the second more populous city in Minas Gerais State (MG). Because of these aspects, they can be considered “medium cities”.

²⁸⁹ There is no consensus about what would be medium cities, even in academic terms: there is no classification that can be used indistinctly by sociologists, economists, architects, geographers, demographers, although for each specialty is possible to find some agreement about the matter. See Amorim Filho; Serra, 2001.

²⁹⁰ IBGE, 2013.

As important regional centers in a specific territorial division, the federal government implemented during 1975 and 1986 a policy to develop such cities in the country in order to transform the national urban net. The results were relative, with better results in the southeast of Brazil than other regions.

More recently, the industrial reorganization that occurs since 1990s is restructuring the Brazilian urban network, emphasizing the medium cities as the dynamic ones. In a process of territorial dispersion, they attract the metropolitan population who migrates searching for economic opportunities. This process of population dispersion redefines the medium city concept itself.

Intense intra-urban process occurs in these cities such as verticalization in central areas associated to commercial and services activities, as well the implementation of suburban-gated compounds to middle and high-income population. Certain aspects of an urban dispersion process can be noticed beside typical big cities problems like favelization, social housing deficiency, violence or even traffic jam.

According to Sposito (2004)²⁹¹, medium cities area facing complex changes in their urban structure with the implementation of centralities in the peripheries and peripheries in the central areas, social and physical fragmentation or crescent segregation that diminishes social coexistence among differences. These transformations induce recent studies about the medium cities in Brazilian urban net.

About Campina Grande (PB)

Founded in 1697, Campina Grande turned into a village in 1790 and a city in 1864. With 400 thousand inhabitants, occupies 594.18 km² resulting in a population density of 673.2 inhabitants per km². The population is mostly urban: in 2010, only 5% lived in the rural zone. Located in between the coast and the backlands of extreme dry conditions (sertão), under the biome named “Caatinga”, the city is in the junction of three different microclimates (Brejo Paraibano, Agreste and Cariri), with distinct vegetation, resulting of Borborema Sierra that surrounds it. The relief presents small undulations, 550 m of altitude and the climate is mild with medium annual temperatures of 22° C, minimum 15° C and highest 33° C.

Although rivers are not of great presence, there are more than a hundred springs around town. Water reservoirs (açude) were implemented during 19th and in the beginning of 20th centuries for diminishing water shortage. Nowadays, no longer serving the original purpose, still stand out in urban landscape. Açude Velho is one of the most important public open spaces for leisure and recreation, gathering cultural equipment. Açude Novo was drained and transformed into a public park (Parque Evaldo Cruz), also in the central area. Açude de Bodocongó, in the northwest region, is a cultural reference in Campina Grande for leisure and festivities, but has no landscape treatment what difficult appropriation by the people. Besides, there is sedimentation caused by irregular refuse placement.

In central area, there are other meaningful public open spaces, squares and parks: Praça Clementino Procópio; Praça da Bandeira, which congregates political manifestations; Parque do Povo that houses the São João party, of national importance, attracting people from different states; Parque da Criança; and other places destined for regional fairs. Excepting for Açude de Bodocongó, these structures define a central cultural and recreative axe, with no similar in the city.

With the recrudescence of environmental legislation, the Master Plan approved in 2006, defines special preservation zones (ZEP) for preservation, maintenance and recuperation of the

²⁹¹ Sposito, M. E. (2004) ‘Novos conteúdos nas periferias urbanas das cidades médias do Estado de São Paulo, Brasil’, in *Revista Investigaciones Geográficas* 54. (UNAM, Mexico). (http://www.scielo.org.mx/scielo.php?pid=S0188-46112004000200008&script=sci_arttext) accessed 15 April 2014.

historical, natural, material or immaterial heritage. The municipality also defined special environmental zones of interest (ZEIA) like São José da Mata, Bela Vista, Cachoeira, and Mata do Louzeiro reserves. Defining a green belt at West zone, they are threatened by the increasing urbanization and still do not have landscape implementation.

Since the beginning, the economy of Campina Grande has commercial basis: it was a trooper destiny and fairs concentration. In the first decades of 20th century, the city was the second world cotton producer, cropped in regions nearby. The industrial production diversified, and nowadays the city is a technological center, with technical and high education institutions like Universidade Federal de Campina Grande, therefore specialized services in the health area.

Between 2010 and 2011, the local GDP increased 23%, from U\$ 2.5 billion to U\$ 3.08 billion, while the capital João Pessoa had an increasing of only 3.08%, from U\$ 5.67 billion to U\$ 5.84 billion. The influence zone of João Pessoa goes from the coast to Campina Grande, which polarizes the interior of Paraíba and other states. Despite its influence, the city has the IDHM of 0.720 in 2010, occupying the 1301^o position among more than 5,500 cities in the country.

Its economic dynamism reflects on the morphological patterns and respective processes. The verticalization with 30-storey buildings, or taller, is significant, without proper evaluation from local authorities of the effects since there is no restrictive zones of implementation and the setbacks are reduced in scale. The entrepreneurs are mostly from João Pessoa and other northeastern cities. The single-family housing pattern predominates in the landscape, with no setbacks or small ones. The urban tissues have mainly 30% of open spaces in the lot (Figures 2 to 4).

Gated compounds to high-income population are a reality, such as Alphaville, implemented by an entrepreneur from São Paulo in a preservation area, restricting the visual access to Borborema Sierra. There are still gated horizontal condominiums of row houses or 5-storey buildings to middle-income people, built with federal resources and private ones, but with no significant open spaces to recreation and leisure, far from the central area and inadequate public infrastructure.

Industrial districts along perimetral avenues or highways and shopping centers (four in project and two more under construction) are similar to other ones around the country in terms of morphological pattern and localization, generating landscapes that no longer present local characteristics.

The existence of public open spaces in urban expansion areas are restricted and do not follow the distribution patterns in central area, of previous consolidation. Urban legislation does not come up with morphological alternatives to the high existing buildings and single-family housing units (Figures 5 and 6). The zoning was repealed and a new one has not been established yet, a conflictive situation. New developments do not follow a previous master plan, but the land offer by major landowners.

About Uberaba (MG)

According to Instituto Brasileiro de Geografia e Estatística (IBGE) estimate data, Uberaba held around 315 thousand people in 2013, constituting the second most important city in the Triângulo Mineiro Region, the second most important economic region in Minas Gerais State. On the other hand, Minas Gerais, with 20.5 million people, is the second most populated state in the country, and its third GDP.

With 4,524 km², and a population density of 69.63 inhabitants per km², Uberaba is largely urban: only 2.23% of its population lives in rural area. Although, the primary sector is highly developed, with the fourth agricultural GDP in the country around U\$ 287 million in 2011. The industrial and services sectors (GDP U\$ 1.12 billion and U\$ 1.98 billion respectively in 2011) characterize Uberaba as a very important medium city, 500 km faraway from three important

urban centers in Brazil: São Paulo, Belo Horizonte (the capital of Minas Gerais State) and Brasília (the capital of the nation).

Located at 764 m of altitude, its relief varies from slightly undulated, predominant in the territory, to very undulated in certain portions of podzolic soil. The climate is tropical with a dry season; the biome is Cerrado, but because agricultural and livestock activities, there are only remains of the original biome. In urban area, the most important river is the rio Uberaba located in the north portion.

Founded in 1809, Uberaba turned into a village in 1836 and a city in 1856 when it was already an important commercial center. With the arrival of the railway in 1889, the economic growth intensified attracting immigrants and the livestock took place, still a significant economic activity.

Until the 1950s, the urban expansion occurred in a very compact way originated from the city center, based on an orthogonal road system that do not considered the undulated relief. Since the 1960s, streams were piped underground or even had their channel rectified in order to create roads in valleys, increasing urban expansion leading to soil sealing and floods, largely in central areas.

From the 1980s and 1990s, the urban expansion resulted in fragmented tissues, growing towards the east-west direction because environmental preservation zones at north and latifundiums at south, which hold back real state actions. Roads and highways are the main

inducers for new endeavors: gated compounds for middle or high-income population, social housing, industrial condominiums and *terrain-vague* waiting for appreciation.

In central area, there are narrow roads, some of them in valleys commonly flooded with summer rains. Bars and other establishments occupy squares by the implementation of gates, with security cabins, privatizing public open spaces, and reducing people's appropriation.

The road system has an orthogonal layout, not compatible to the relief, and although the slopes are not so intense, ramps could be avoided with a proper design. Some recent gated compounds for high-income population have an organic layout. The pattern in Uberaba is narrow sidewalks with few trees.

The park system has three parks classified as environmental conservation units, two of them very much used: Parque da Mata do Ipê (3.5 ha) and Parque Jacarandá (3.3 ha) where there is a small zoo. The third one, classified as a municipal natural park, is Mata do Carrinho (13.3 ha), with low frequency.

There are also two more important parks, not classified as environmental conservation units: Parque das Acácias (12 ha), very much used for walking, beyond rain water containment through retention and detention ponds; Univerdecidade Complex, designed to house leisure areas, as well a technological center, universities and government buildings; nowadays there are Parque das Sibipirunas (very much abandoned), the head office of a federal university and a gas turbine research and development center, under construction. The complex has a great potential for future use, despite of violence problems resulting from bad quality maintenance and low attendance.

The main environmental conservation unit is located at north portion named Área de Proteção Ambiental do Rio Uberaba with almost 53.5 thousand ha, including 8% of its area in urban perimeter. The main objective is to ensure the source used to provide water for Uberaba. From the total area, 25% are used as pasture, 27% as fields, 18% as agriculture, beside 9% as forests and 21% as Cerrado.

The urban tissues, already consolidated, present high occupancy in lots that have less than 30% of open spaces and one or two setbacks (Figure 7); there is a predominance of small size horizontal buildings (up to 4 floors); blocks have less than 10% of forestation with small amount per lot.

The preliminary verticalization occurred in central areas, characterized by a high level of occupation and no lateral setbacks. Presently, new buildings have four setbacks, but still with high level of construction for a city the size of Uberaba: between three and four times the lot area and less than 50% of open spaces.

The urban expansion, the most significant process, has two main patterns: Gated compounds for middle and high-income population, with serious impacts on public open spaces appropriation; Federal government housing program named Programa Minha Casa Minha Vida (PMCMV) finances different endeavors, from gated horizontal condominiums to small buildings with no lift; the open spaces have restricted access. The program is intended to low-income to low-medium income population and until August 2013, more than 5 thousand units were delivered.

The entrepreneurs responsible for these endeavors are not only local ones, but also national companies of different scales, some of them working in many states. The fragmented urban expansion that takes place is very much common in the country, deriving landowners and entrepreneurs significant profit. However, there are negative impacts on the urban density and environmental consequences, from the increasing of displacements by private cars and motorcycles (in 2012, Uberaba had 182 thousand vehicles - 100 thousand cars and 40 thousand motorcycles) to the decreasing of public open spaces usage in the neighborhood scale.

About Uberlândia (MG)

As mentioned before, the population of Uberlândia is 646.7 thousand inhabitants (2013), 97% living in urban area. The territory has 4,115 km² and a population density of 157.15 inhabitants per km². The city integrates the region called Triângulo Mineiro together with Uberlândia and Araguari. Located 550 km from the state capital Belo Horizonte, the connection is easily realized by highways that also reach São Paulo, Rio de Janeiro, Goiânia e Brasília, as well other important Brazilian cities. It is the most populated city in the interior of the state of Minas Gerais.

Its origin remotes to 1818 and the economic growth increased after the arrival of the railway Estrada de Ferro Mogiana in 1895, together with the implementation of the orthogonal road system. The biophysical environment can be characterized by 1000 m of altitude, and a

maximum slope of 967 m; the existing biomes are Cerrado (prevailing) and Atlantic Forest (Mata Atlântica); the annual medium temperature is 22°C, plateau is the predominant relief with 70% of undulated land and the rest is flat, ideal for outside leisure activities.

The three most important basins in urban area are rio Uberabinha, rio Araguari and rio Tijuca. Rio Uberabinha, still not piped underground, cross the entire city and it is responsible for water supply. The stream São Pedro is an urban reference: nowadays is piped underground, under Marechal Rondon Avenue, in the city center, which, since the colonial time, presents a significant group of squares very well maintained and intensively used.

During the first decade of 20th century, by the influence of urban improvements in Rio de Janeiro (1902-1906), some squares were created and other streets receive urban forestation. These initiatives were lost afterwards.

The local economy was incremented by business tourism, industries, livestock activities, services and logistics warehouses of nationwide companies such as Martins. The existence of a federal university and three shopping centers indicate the city centrality.

There are innumerable social and sports clubs and eight big parks: Sabiá, Uberabinha, Siquierolii, Bons Olhos, Gávea, Santa Luzia, do Óleo e do Carvão. The two most important are Parque Sabiá – at the east region, it is composed by a zoo, lakes, aquarium, cooper trail – and Parque Municipal V. Siquierolii – at the north region, it concentrates a museum, recreational equipment for children, and significant Cerrado specimens. Both are largely used by the population. There are eleven environmental protection areas, but 50% of urban land can be classified as vacant land. There is a linear park of Rio Uberabinha (Figure 8), but only 2 km of the 7 km foreseen are already implemented. The population approved the construction and aims for its finalization. The financial resources originated from environmental sanctions named TAC (Termo de Ajustamento de Conduta), involving a private company (Sadia) and a social club (Praia Clube).

Figure 8. Linear Park along the river Rio Uberabinha. Source: Lab-QUAPÁ.

The road system reflects the urban expansion history: there is a segment corresponding to the central area implemented during the colonial period with narrow streets, not orthogonal. Then, around it, there is the orthogonal system and, more recently, fragmented segments, where roundabouts are used as squares.

Important urban process are the recent verticalization, from medium to high buildings; the implementation of closed gated compounds; and the invasion of private and public land by social movements that request housing.

As an example of the first process is Santa Mônica neighborhood with 4 or 5 storey buildings (social housing) constructed by the federal government program named Programa Minha Casa Minha Vida (PMCMV). Although, the major program operation is the construction of single-family houses, thousands of them, of small area, few meters of frontal setbacks, walled by the owners, at the city fringes. Another social housing program is the Programa Planta

Popular towards land property regularization. People can choose among 19 different projects, from 36 to 70 m², with reduced open spaces.

The gated compounds for middle and high-income population (Figure 9) are located in suburban areas, disconnected from the main urban tissues. The social movements responsible for the invasions (Figure 9) are very much organized, creating street layouts and lot division.

Figure 9. Gated compounds and social movement occupation in Uberlândia. Source: Lab-QUAPÁ.

The main stakeholders are the federal government, entrepreneurs and SME, social housing movements and the landowners. The main vacant land belong to only six families. The urbanization processes are very dynamic, reflecting in the urban form as well in the open spaces, public and privately owned ones.

Conclusions

The research about the three medium cities denoted some common aspects even as specificities, all-important to the understanding of the open space systems in the urban form constitution.

Uberaba and Uberlândia, located under altitude tropical climate with strong rains during summer time, witness floods that implicates in a revision of urban typologies along river and

streams. Campina Grande, characterized by a semi-arid climate, has lower rainfall levels, and the former reservoirs (açudes), no longer water suppliers, are open spaces systems with potential for public use and appropriation.

The building legislation, or its absence, results in different verticalization patterns throughout time. In all cities, the central areas have suitable square system distribution, which compensates the high densification from buildings with no frontal or lateral setbacks. The absence of a zoning legislation in Campina Grande facilitates the 30-storey buildings, what is not observed in Uberlândia, the most dynamic economy among the three cities. This dynamism in part resulted in large avenues, of recent construction, with sidewalks of better and proper dimension.

On the open spaces point of view, focused on leisure, all cities have important parks, intensively used, but with distinct characteristics: Campina Grande presents a park system along the reservoirs (Açude Velho and Açude Novo), properly forested, in opposition to an extensive paved area to the realization of popular parties, nationally famous; In Uberaba, one of the biggest parks and intensively used is Parque das Acácias designed to rain water control; Uberlândia, despite public parks of good dimensions, has many social and sports clubs, also intensively used, indicating specific cultural habits; The analyzed urban tissues present, in general, high levels of land occupation; lower levels of urban forestation (intra-blocks and on streets); narrow and poorly maintained sidewalks. In central areas of Campina Grande and Uberlândia, streets are suitable for pedestrians needs, revealing a former urban care lost during the last decades.

The extensive urban expansion, in the three cities, has similarities: The program PMCMV has a significant operation, even though stronger in Uberaba and Uberlândia; Gated compounds for middle and high-income population can be found in all cities, though in smaller number in Campina Grande with the lowest GDP per capita; Logistic warehouses, industrial and commercial centers are implemented along highways and perimetral roads, increasing the complexity of the peripheries.

The recent economic growth in all three cities is revealed partially in urban form, but with no qualification of the open spaces systems, or even urban form control (open spaces and built ones) objecting an urban space idea towards conviviality and urban landscape enjoyment.

Abstract. *The study area is located in the city of Rio de Janeiro, capital of Brazil's second largest metropolitan area, with 6,323,037 inhabitants. The geographical position favors the dominance of wet/semi-wet tropical climate with large seasonality (wet summer, dry winter) and spatial variability. We adopted the channels watershed as our studied area. The proposed methodology of defining landscape units was applied as a tool for urban spatial analysis and for an environmental diagnosis combining geo-biophysical and urban-architectural features. As variables, we applied the characteristics of relief, hydrology, cover surface soil types, land use and occupation aspects; urban form settings. Four landscape units were defined, due to its significant heterogeneity associated with geographical location. Relief conditions were instrumental in the spatial distribution of hydrological flows and, consequently, in the territorial occupation shapes and the quality of urban life, being nowadays one of the main determining factors for existing urban patterns. The article presents the intersection of geo-biophysical and urban-architectural dimensions, the comparative study of landscape units and their type-morphological characteristics, by considering the occupation density, the structural physical elements of the urban fabric and the incidence of open spaces.*

Key Words: *Landscape Ecology, urban form, geo-biophysical constraints, territorial planning, environmental risk*

Introduction

In this paper, we will present the results of the morph-functional and morphological type analysis and classification of the study area in the city of Rio de Janeiro/Brasil, located in the area covered by the Urban Structuring Plan of Vargens, promulgated in 2009. In order to understand the relationship between the urban parameters and the occurrence of vulnerability and risk conditions in urban areas, especially when they refer to climate changes, the scope of this project covers the range of everyday relationships, of daily life achievements, hence it is restricted to the range of microclimatic action. Given the relief characteristics of the city, part of everyday life of the population occurs in settlements located in slopes and, in some situations, under conditions of extensive vegetation cover, such as forests and small farming areas, remnants of an agricultural past still recent.

This fact has reinforced the importance of the adoption of watershed cover unit as a criterion for defining the study area, taking as spatial delimitation of this research the Channel's Zone sub-basin, which integrates the Jacarepaguá Basin, located in the Western Zone and being the current urban expansion area of the city.

This article is the result of a multidisciplinary research project funded by Research Support Foundation of the State of Rio de Janeiro (FAPERJ-E-26/111.626-2011), aiming to analyze the impacts of climate changes in urbanized and non-urbanized landscape. It is associated with the project "From urban forests coastal plains: a geo-ecological approach on urban environmental systems" (FAPERJ-E-26/102.984-2012). To meet the proposed objectives, the following goals were set:

- (1) Relate social-environmental (urban), the physical-environmental (geo-ecological) and comfort parameters in the use of urban spaces;
- (2) Generate new ideas for urban laws and urban plans formulation that consider the environmental, climate, comfort and risk constraints;
- (3) Enhance researchers and student's training, with innovations in teaching and research in Geography, Urban Ecology, Architecture, Urbanism and Landscape, with the incorporation of methods for the preparation of three-dimensional scenarios considering socio-environmental, physical-environmental, comfort and micro-climate as related aspects.

The adopted strategy was to approach the concepts, methods and procedures through a trans-disciplinary, multi-scale and integrated vision to deal with the built environment in contexts of great complexity. In this article, we highlight the following themes, concepts and methods:

- a) Hydrology, forestry and urban climatology;
- b) Vegetation cover;
- c) Legislation and urban parameters;
- d) Types and characteristics of the built and non-built spaces.

Methodological procedures

The landscape was adopted as a spatial analytical category by considering the multiple interactions between its various constituents which, according to Forman (1995), compose “a mosaic where a cluster of local ecosystems is repeated in similar form over a kilometer-wide area”. Because it is an area of urban expansion of the city, the adopted delimitation encompasses a very heterogeneous mosaic where fragments of native ecosystems, already altered by successive uses, alternate with different land use and cover characteristics, resulting in a palimpsest with grooves of different economic times which Naveh (2000) identifies as co-evolutionary cultural landscape:

“Cultural landscape thus creates a tangible bridge between human minds and nature. Because of the co-evolutionary process of mutual modification and adaptation of humans and their natural environment in cultural Total Human Environment landscape, the delineation between social and natural systems in socio-economic models of landscape processes is completely arbitrary and artificial.” (Naveh, 2000 p. 18/19)

The geographical approach of landscape ecology and landscape architecture was used as a theoretical-methodological support to the urban and territorial planning underway. Two methods of analysis were adopted: a morph functional analysis of landscape ecology, based on the interactions between the landscape elements and their functions (Forman, 1995), and the urban morphological type analysis (Metzger, 2001; Forman, 1995; Macedo, 1993).

Starting from this principle, we selected the portion west of the Jacarepaguá water basin, since it is its last expansion frontier. Based on the experiences acquired in previous researches (Name, Montezuma; Sesana, 2011; Montezuma; Oliveira, 2010; Montezuma *et al.*, 2012a; Tangari *et al.*, 2007; Schlee; Tangari, 2008; Schlee *et al.*, 2009), and with the purpose of best describing the morph structural features that characterize urban space under expansion, the landscape was initially analyzed in its multiple interactions and constituents, according to Forman (1995).

From the identification of landscape units, defined in this work as land surface with similar hydro-geomorphological characteristics and human modification pattern's history (Metzger, 2001), we established the two major dimensions that comprise the study area: a geo biophysical dimension – which refers to the support condition on which human life and occupation are held - and the architectural-urban dimension, which comprises the set of objects that will promote the territorial configuration.

After the sub-division in specific landscape units and its analysis, thematic maps were produced featuring the systems of each dimension.

Geo biophysical dimension

This covers the set of elements of geo biophysical support, such as: relief characteristics; hydrology; surface coverage and land use. These were identified through the interpretation of satellite images, over flights photos and ground surveys (Forman, 1995; ROSS, 2009).

In order to characterize the relief, the mapping made by Roncarati and Neves (1976) was first used to help identifying the geomorphologic compartments. Both the ranking of surface coverage and use and the actual and potential drainage were taken from high resolution satellite image – Geoeye, 2011 (resolution 0.5 m) and then classified in a key based on the critical analysis of the specific literature and on the one adopted by the Brazilian Institute of Geography and Statistics (IBGE, 2012).

As a result of this process, maps were produced in order to represent the main features of the basin, such as: (1) Terrain Digital Model (MDT), featuring the relief surface and slopes in the mountainous compartment; (2) Hydrological Map, contemplating the characteristics of drainage and the representation of both potential and real water bodies, such as the main drainage axes, channeled or not, artificial channels, lagoons, lakes and artificial reservoirs, and (3) the Surface Use and Coverage Map, showing the spatial distribution of major vegetation categories in the conservation zones, built area and remnants of native ecosystems (inserted or not in the protected conservation zones) and features of exposed substrates, such as soils, rocks and access roads.

Urban-architectural Dimension

This dimension encompasses urban structural elements, according to their functional and formal profiles, identified through interpretation of satellite images, over flights photos and ground surveys. Based on previous work (Schlee *et al.*, 2009; Wopereis, Capillé and Tangari, 2011) and according to authors that conceptualize urban morphology (Lamas, 1992), the relationship between urban design, landscape (Campos *et al.*, 2012 and 2011) and open spaces systems (Magnoli, 2006a and 2006b; Macedo *et al.*, 2007), the following elements were considered in the first layer of analysis: land use and occupation; urban fabric and building typologies, including blocks, lots and buildings; circulation systems (streets and sidewalks); open spaces systems of environmental character (protected areas with restrictions on parceling regulated by environmental protection legislation, protected areas with no restrictions on parceling regulated by environmental protection legislation, conservation units); open spaces systems with urban character (areas susceptible to parceling, regulated by urban legislation codes).

Once the boundaries of the landscape units were defined, each one was described. Based on the morphological type analysis, each unit was divided into landscape subunits. This process enabled the identification of a second output level of heterogeneities in the spatial production and, consequently, of the diversity of the urban fabric in consolidation.

Results and discussion

The definition of landscape units from morph functional and morphological-type analysis proved to be a key tool for the identification of the urban characteristics and related processes in the study area.

Morph functional analysis: division into landscape units

The average rainfall in the city of Rio de Janeiro varies between 1000 and 1200 mm/year (Dereczynski *et al.*, 2009; Togashi, 2009). Galvão (2009) recorded, in 1958 in the Jacarepagua Plain: an annual total of 942 mm in the mountains; 1,288 mm in the piedmont; 1,872 mm in

the plain. In recent times, it was recorded in the Caçambe River basin an annual precipitation of 1900 mm in the mountainous area (Togashi; Montezuma; Leite, 2012; Montezuma *et al.*, 2012). These results highlight the localized distribution and confirm the function of relief subdivision as a major factor in the local dynamics. From this data we established that *a priori* the main risk factor is linked to rainfall and hydrological dynamics as a whole.

After identifying the risk factor, we analyzed the terrain features from the physiognomy by initially establishing three major analysis units: hill (mountainous area), mountainside base (peripheral clinopiano) and plain (lowlands).

Given the above, the geomorphology was identified as the structuring and conditioning element of the main characteristics of the terrain, establishing itself as the first item in the hierarchy of landscape division. The second parameter adopted was the characteristics of ground cover, since these summarize the behavior of the physical and hydrological conditions that prevail in each compartment (Montezuma; Oliveira, 2010). Both the remaining natural vegetation and the secondary coverage developed in unused, abandoned or cultivation areas were associated with the characteristics of urban fabric, completing the set of criteria used for the study area division and characterization. This classification resulted in four Landscape Units, ordered in the north-south direction and defined as follows: LU1, LU2, LU3 and LU4 (Figures 1 and 2).

LU 1: Slopes Forestry Domain: mountainous province/crystalline basement

Crystalline basement area (Roncarati & Neves, 1975; Costa Maia *et al.*, 1984). Vegetation in forests mosaic of different ages and single family cultures, mostly composed of banana plantation and in a lesser proportion subsistence plots, dominates. Few buildings, mostly one floor high, and low soil sealing rate. It encompasses the neighborhoods of Vargem Grande and Vargem Pequena.

LU 2: Interface Forest/Building Zone Domain: peripheral clinopiano/piedmont

Lowland zone slopes base, formed by sediments of continental origin (Costa Maia *et al.*, 1984). Vegetation can be found in private lots in the form of large backyards or gardens. There is a predominance of single-family units with 1-2 floors placed in large lots, low rate of soil sealing, occupied in general by small farms, orchards, farms and rare stables. It is located in the central portion of the neighborhoods of Vargem Grande and Vargem Pequena.

LU 3: Low Density Building Domain: paludial plains

Presence of swamps fragments and some remnants of sparse swampy woods. The soils are moist and very humid, with predominance of peat. This is a landscape unit with low density of buildings, occupied by small farms and orchards in progressive process of replacement by fenced residential condominiums, which are generally composed by two to three floors buildings. Low tree plantation and vegetation fragments can be found inside private properties. It corresponds to the southern portion of the neighborhoods of Vargem Grande and Vargem Pequena.

LU4: High Density Building Domain: elongated barriers

Sandy soils of the ridges associated with lagoons. High rate of fenced residential high-rise condominiums, low tree plantation, generally composed by palm trees, vegetation in private gardens. Located in neighborhood of Recreio, it corresponds to the main expansion area of condos of the entire Jacarepaguá Plain coastal line.

Considering the significant landscape transformation in Jacarepaguá Plain since the colonial period, the current observed physiognomy results of an already much altered cultural landscape.

The last transformation process dates from the early twentieth century, after a succession of production attempts started with the production of sugar cane plantations, coffee plantations, subsistence agriculture and coal and firewood exploitation, closing the last phase of rural economy in the area.

During this period, in the mountainous domain on the southern face of the Pedra Branca Massif, the agriculture activity of annual species was practiced, notably the cultivation of banana. This was due to higher period of shading, high humidity, more consolidated soils and better drainage. The plain domain was left to vegetables growing (potatoes, yams, tomatoes, cassava, chayote), mainly on the areas of the lowlands flooded portion. In the intermediate zone between the mountain and the plain (peripheral clinoplane) urban settlements were initiated, with the establishment of first roads, houses and mills, playing an important role as the center of economic convergence of production and exchange between the two adjacent zones (Galvão, 2009; Magellan Correa, 1932). The roughness of this historical process is present along the basin and partly explains the spatial distribution of the occupation patterns in the whole area.

The landscape morphological analysis reflected an occupation pattern that is repeated and results from a socioeconomic system of dependency between social classes whose settlements have clear distinctions in the built environment. This fact is interpreted by the high presence of informal communities in all landscape units, especially nearby private residential condominiums, along river margins or hillsides.

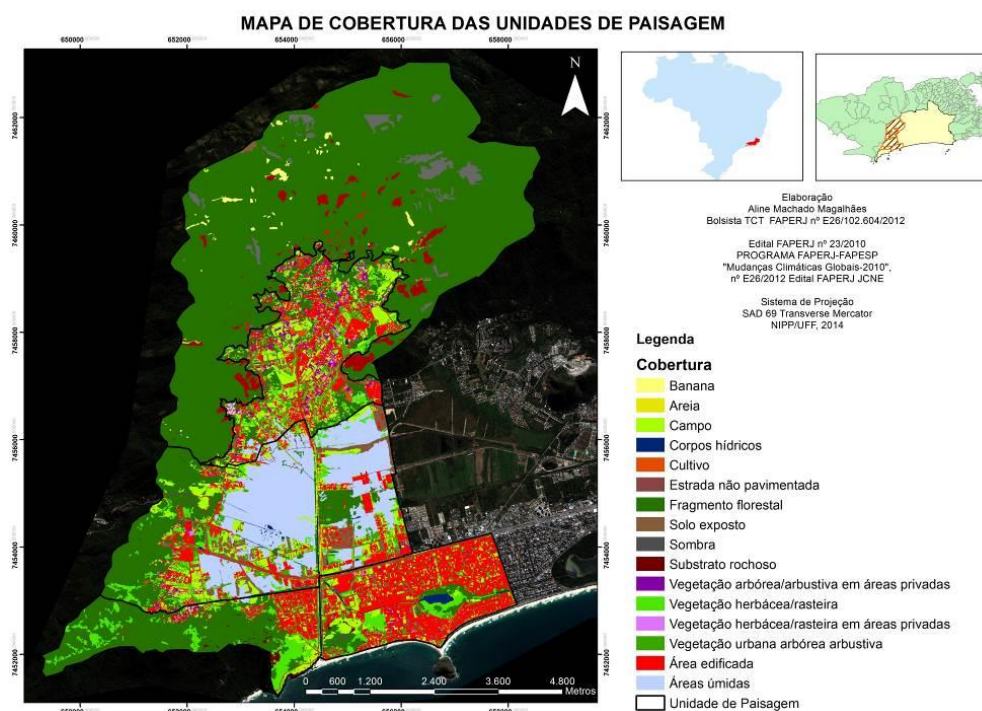

Figure 1. Map of cover and land use surface, with the delineation of the landscape units. Jacarepaguá Plain/Rio de Janeiro/RJ,Brazil (source: Ellaborated by NIPP/POS GEO-UFF CNPq Research Group, on 2011 Geoeye satellite image, 0.5 m resolution).

The morph functional analysis, revealed a spatial-temporal differentiation, which demonstrated a chronological alignment. Based on Santos (2012):

“The landscape is not created at once, but for additions, replacements; the logic by which an object is made in the past was the logic of production of that moment. A landscape is a writing over the other, is a set of objects that are of different ages, is an inheritance from different times (Santos, 2012, p.72-73)”.

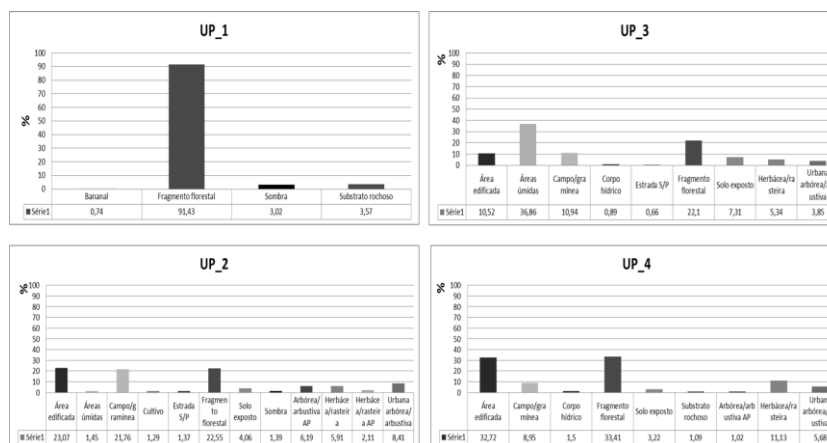

Figure 2. Percentage of surface use and coverage in the Channels Basin, Jacarepaguá Plain/RJ. (source: Magellan and Montezuma, in press).

The current territorial configuration seems to be founded on the compartmentalization of relief, but also on how it has conditioned occupation patterns that now influence the behavior adopted by the real estate capital. As reported in Galvão (2009), although there may be common elements in each unit, specific features individualize each region in which the land ownership system evolves depending on the economy or colonization type installed, but also grounded in different relief conditions.

According to that, the old production activities of rural past are concentrated to the north in the forest of hillside area, in LU1, and more modern occupation patterns are notably present in LU4, on the sandy soils of the ridges. The mountainous terrain conditions, where more than 80% of slopes range from less steep to severe steep slope (Montezuma; Oliveira, 2010), presented at the time a less immediate return to undertaken investments, allowing the persistence of preterit use and occupation patterns, associated with agricultural production - chayote, cassava, sweet potatoes and corn – and, to a much lesser extent, with the small livestock for subsistence and mules as a resource to the workforce needed to land management (Correa Magallanes, 1932), freezing the form aspects over time.

With the creation of the Integral Protection Conservation Unit in the form of the Pedra Branca State Park, the gradual reduction of subsistence plots and the restriction of residential uses in the higher portions of the coastal range took place. This system of land forms and uses in LU1 resulted in a setting of greater vegetation cover and restricted, sparse buildings, enhanced by the urbanization deficiencies due to the condition of the environmentally protected area.

In LU2 the concentration of large lots and land parcels in the foothills (peripheral *clinopiano*) and the ensured forested conservation areas add value to the land in the surroundings, valorizing the current occupations and attracting new ones. However it is permissible to consider that the geographical position of this area corresponds to the buffer zone between the depositional processes of the slopes at the interface with the low lands and that there are, in some parts, existing *talus* depots (Roncarati; Neves, 1976), which indicate the need for a more restrict occupation process.

In LU3, the rarefied occupation pattern in the central portion is primarily the consequence of wetlands and floodplain soils and of the remaining lots of temporary agriculture. The characteristic occupation condition and the fragile land ownership situation, developed during the first settlements period, facilitate the negotiation made by shareholders, reflecting the gradual replacement of extensive open private spaces by a pattern of fenced communities that stands out against the predominance of older and more modest and less urbanized dwellings.

Finally, the denser and built standard in LU4 is explained in terms of a prime waterfront location, established from recent years, along with soil structural conditions. The higher land values stimulate the highest number of real estate investments in residential units and the

difficulty of horizontal expansion, due to the lack of empty lots, leads to high rise building increase and to reduction of open and more wooded spaces, creating a more uniform pattern in shape and spatial organization.

Type-morphological analysis: division into landscape subunits

This study was based on field surveys, over flights photos and satellite images, and considered the urban fabric features as the second most relevant criterion of analysis, as they reflect, along with the remaining vegetation, the prevailing conditions on the ground surface. The result obtained for each unit landscape, described above, was the division into two sub-categories: Consolidated Urban Fabric, where parceling and building processes occur; Unbound Urban Fabric, referring, in general, to non parceled areas, where there are large tracts of specific use (clubs, studs, among others), land in the process of excavation works or sectors with isolated buildings, located mostly in the forested sector.

The Consolidated Urban Fabric was initially differentiated in terms of the existing morphological structure and according to the main element that defines that structure, which may be linearly guided by a track or orthogonally organized in a block system. Due to intense incidence of streets inside fenced communities, which therefore have low accessibility, this parameter was considered crucial for the study area characterization. The variables of the lots density occupation (low, medium or high density) were added due to the need for differentiating the residential types identified. The occupation density defined in this work refers to liquid density, analyzed through the occupancy of lots and blocks, withdrawing from that calculation the public open spaces (streets, squares, parks).

Thus, based on previous studies (Wopereis, B.; Capillé, C.; Tangari, 2011; Campos *et al.*, 2011, 2012), we applied the percentage of density, according to the incidence of open spaces and high rise building in private areas, such as individual lots or condominium blocks. The percentage incidence of open spaces matches: high density (up to 30% open spaces surface inside the lot or block); medium density (between 30% and 50% of open spaces surface inside the lot or block) and low density (more than 50% of open spaces surface inside the lot or block). The percentage incidence of high rise building (up to 3 floors or more) matches: intense high rise building incidence (over 50% of the surface inside the lot or block); medium high rise buildings incidence (between 10% and 50% of the surface inside the lot or block); low high rise building incidence (less than 10% of the surface inside the lot or block).

Within this sub-category, and based on the above classification, we investigated further the presence of empty land parcels or parcels with specific use, the latter with commerce, industry or services utilization. In total, a score-board with thirteen landscape subunits in the Consolidated Urban Fabric sub-category was obtained through the crossing analysis between the structuring elements and the occupation densities (Tables 1 and 2):

LU1 presents low heterogeneity and occupancy rate, because it refers to the coverage area of the Pedra Branca State Park. This unit stands out for the highest heterogeneity of the consolidated urban fabric (Figures 4 and 5). With 22 boundaries (including 16 inside the LU2), the areas structured through private access streets with medium occupation density were the ones most frequently identified. The presence of large tracts is considerably high, summing up to 14 lots of specific use and 15 without apparent use, also indicating an area with high potential for change and urban consolidation.

LU3 and LU4 Landscape Units show low heterogeneity. LU3 differs by presenting non built large tracts in areas already urbanized with geo-biophysical features which make them more sensitive to the occupation. LU4 is characterized by high degree of high rise buildings and dense occupation.

Table 1. Classification of landscape sub units observed in the Consolidated Urban Fabric category.

Street as the structuring element:	Block as the structuring element:	Large tracts
<ul style="list-style-type: none"> - Public access street (low density) - Public access street (medium density) - Public access street (high density) - Private access street (low density) - Private access street (medium density) - Private access street (high density) - Non paved street(low income communities) 	<ul style="list-style-type: none"> - Public access block (medium density) - Public access block (high density) - Private access block (medium density) - Private access block (high density) 	<ul style="list-style-type: none"> - Large tracts of specific use - Non built large tracts

Table 2. Landscape subunits identified within each landscape unit.

Landscape Subunits	Landscape Units				
	LU1	LU2	LU3	LU4	TOTAL
- Public access street (low density)	0	8	2	0	10
- Public access street (medium density)	0	8	2	0	10
- Public access street (high density)	0	1	0	1	2
- Private access street (low density)	0	6	1	0	7
- Private access street (medium density)	0	16	5	1	22
- Private access street (high density)	0	6	6	2	14
- Non paved street(low income communities)	0	5	5	2	12
- Public access block (medium density)	0	0	0	2	2
- Public access block (high density)	0	0	0	1	1
- Private access block (medium density)	0	0	0	1	1
- Private access block (high density)	0	0	0	2	2
- Large tracts of specific use	0	10	4	0	14
- Non built large tracts	0	13	2	0	15

Final considerations

In landscapes Ecology, the systemic approach is widely used to understand the integration between the parts of a whole and the different levels of action, direct and indirect, of the landscape elements.

“... in applied terms it contributes when it proposes dealing with anthropogenic environments, in the scale in which man is transforming the environment, seeking to understand the structural changes and, thus, functional, brought by man in the mosaic as a whole,

incorporating explicitly all the complexity of spatial inter-relationships between its components, both natural and cultural.” (Metzger, 2001 p.7)

The combination of landscape units, besides being necessary to understand the properties that emerge from the set (Naveh, 2000), revealed a certain degree of interdependence between them. Forested areas upstream act as storage zone to supply the massive rainfall which has in the mountains its main barrier to transposition. The redistribution of the surplus that flows through the plain has the paludial zones of UP3 and lagoon systems of LU4 as the main reservoir.

Analyzing all together, we conclude that the extreme heterogeneity is also expressed in the urban fabric, prevailing the consolidated type, with structuring streets which cross through the landscape in a linear pattern and to which are coupled parallel systems of residential occupation of single family character. The current trend of the residential type points to the almost complete occupation of the land, whose lot dimensions are decreasing, but remaining single family use, usually not exceeding two floors buildings, but which will suffer intense transformation processes due to increase of soil and changes due to legislation codes, as is being studies in complementary researches with simulative occupation scenarios until 2016. This trend will cause changes in hydrology, urban microclimate and comfort, which represent aspects that have been developed by our research, trying to provide support for normative formulations and design alternatives that may enable more appropriate conditions to future the occupation.

Land use and occupation patterns of coastal plain require adjustment in order to prevent that both the density as well the soil sealing worsen the risk of flooding that are proper to the local dynamics. Therefore, it is essential that criteria for urbanization are adopted having as parameters the constraints associated to the particular landscape dynamics, such as topography and hydrology, the main landscape structural factors and regulatory agents of comfort and environmental health of the resident population.

The landscape of sprawl: relationships between natural and urban dynamics in the Western Portion of the Metropolitan Area of São Paulo

Leonardo Loyolla Coelho; Silvio Soares Macedo

Laboratório Quapá, Faculdade de Arquitetura e Urbanismo, Universidade de São Paulo

E-mail: lloyolla@usp.br; ssmduck@usp.br

Abstract. *An increasing part of the urban development of the Metropolitan Area of São Paulo (with its population of nearly 20.1 million people in 2013), as so many others in Brazil, is structured on urban sprawling, conforming a variety of urban fabrics with different morphologic attributes – low-rise housing, gated communities, industrial areas, high-rise buildings, and so on – sometimes not related to each other and presenting a huge social disparity. Its Western Portion exemplifies these attributes, as it presents an urban development structured along the three main road axes, especially since the 1970's. These actions have a great impact on environmental dynamics and on its urban conformation. On the other hand, the urban sprawl contributes in an unplanned manner to the preservation of environmentally significant open spaces in this area. The approach from a landscape-planning perspective is imperative to portray the effects of this urban development process within the environmental dynamics and to elaborate urban projects and public policies for the area. However, we shall guarantee a proper connection between the remaining environmental areas, adding urban value in a way that honors the population's public right of use/enjoyment to these spaces in order to actually build an urban landscape.*

Key Words: Open spaces, urban sprawl, landscape planning, Metropolitan Area of São Paulo.

Introduction

When driving to the outskirts of large Brazilian metropolises, an observer has the chance to get in touch with successive landscapes that are characteristic of the Brazilian urbanization processes in the early 21st century. Vast gated areas enclosing residential wooded havens, large warehouses settled on huge land slopes, gas stations that actually end up hosting all sorts of services, remains of native woods, and large, precarious settlements that spread out to the horizon with substantial damages to the local terrain and hydrography. Urban fragmentation and dispersion are characteristics of this succession of landscapes (Figure 1).

Figure 1. Landscape resulting from the disperse urbanization process. Drawing: Silvio Soares Macedo, 2014.

Relationships with new scales are also created, where large portions of the land are crossed by infrastructure elements, such as power transmission lines, water reservoirs, water dams, railways, or large urban portions deeply isolated from their surroundings. People - pedestrians, drivers, or commuters - are no longer able to comprehend the scale of such a landscape.

This work is part of a doctoral dissertation for the School of Architecture and Urbanism of the University of São Paulo (FAUUSP) and is included in the objectives of the research named "The open spaces systems in the Brazilian urban form constitution: production and appropriation" (2012-2016), developed by the network of researchers denominated Quapa-SEL and coordinated by FAUUSP Quapa Laboratory, in an attempt to understand the relationship between open spaces and urban forms through the analysis of several Brazilian cities.

Sprawl in Brazil

Sprawl is characterized by the creation of discontinuities in the urban fabric as a result of the occupation of areas that were originally rural, with gaps between adjacent, continuous urban clusters. Such definition is used as a reference in this essay and is based on that made by Reis Filho, who defines this concept as "the trend to distribute urban infills over all territories affected by the process among typically rural areas, leading to a relative homogenization of these territories." (2006, p. 51, free translation). With this definition, the author aims to differentiate it from the concept of "urban diffusion", as used by European authors such as Indovina (1990), Portas (1993), and Secchi (1995). Such differentiation is justified by the fact that the term "diffusion" evokes the possibility of a "complete urbanization" in the future, whereas Reis Filho understands the process as the distribution of urbanized points.

North-American theorists have approached similar issues since the 60's, with emphasis to the pioneer concepts of urban sprawl, proposed by Harvey and Clark (1965), and leap frog development, proposed by Gottman (1961).

The fragmentation of the urbanization process in Brazil is not recent. Significant parts of the urban history of São Paulo and Rio de Janeiro have occurred in this manner, when the perimeter of these cities went beyond their initial downtown area. What distinguishes recent dispersion processes from previous processes is not only the type of urban fabric produced, but also its structuring mode, which started to occur under the influence of legal mechanisms and not exclusively as the result of speculative land interests.

Reis Filho (2006) subdivides the Brazilian disperse urbanization into three types and classifies it according to the uses attributed to it: industrial, residential, and that related to commerce and services. These three types have intrinsic relationships, as the installation of industrial areas usually attracts housing areas to its surroundings (either formal or informal settlements), which, on their turn, demand a respective support infrastructure.

Pressured by the mobility problems of large cities and free from the technological restrictions that forced them to remain in close proximity to them, companies started to find productive advantages in moving away from the compact city and sought for sites near major connection axes. The social groups related to these productive activities try to accompany this relocation and create urban agglomerations near their job sites, either legally or not.

In addition to the productive restructuring, other factors have contributed to intensify the disperse urbanization process in Brazilian cities.

These factors include the residential dispersion stimulated by high costs of living and plots in the compact city, which motivate the search for new locations to live with lower buying power, but still quickly connected to access highways. This adds to the search for locations that meet the consolidated image of an isolated home with large backyards surrounded by nature.

Another important role is played by the search for a second residence in the surroundings of Brazilian metropolitan areas. In his work about the structuring of Greater São Paulo, Langenbuch (1971) shows that an occupation process occurred in the 50's in several peri-urban

areas for recreational purposes, with a model based on country houses resulting from a real estate speculation cycle.

Moreover, problems such as the increased urban violence and the low effectiveness of the Government Authorities to combat criminality in Brazil have given the private initiative the opportunity to offer walled, gated communities and the implementation of ostensive security systems.

As of the 70's, in the specific case of Brazil, this group of factors resulted in elite neighborhoods present also in urban fringes (Caldeira, 2000) using models inspired in suburban standards of richer countries.

Even though this form of urbanization is developed for small portions of the population, it has major implications for society (Ojima, 2007, p. 104), as the structuring of these areas is based on an extensive logic and involves the creation of large support structures.

The migration of a part of the elite to the urban outskirts gives rise to a new suburban standard in Brazil, with the periphery occupied by all income classes.

The urbanization of the contemporary city is characterized by the creation of spaces where the boundaries between rural and urban very often are no longer perceptible. The production relationships that used to have an urban character now take place in areas with rural characteristics²⁹².

This urbanization process establishes new dynamics, such as the higher dependence on automobiles. A new time-space relationship is created, where distances play a role that is less important than the time spent in commuting, and speed becomes less important than the traffic flow²⁹³.

Highways play a very important role in the daily lives of those who live in disperse urban areas. Whether in an SUV with a single occupant, on a shuttlebus, or on an ordinary bus packed with commuters, a considerable amount of time is spent on highways and one has at least a daily contact with them.

As a consequence of the popularization of mobility, urban centers to support these disperse housing areas grow in number, with an infrastructure of commerce, services, and leisure.

In addition to the appearance of support equipment motivated by a specific form of mobility, the disperse urbanization process has also fostered an increase in the number of private recreational open spaces. The private sectors finance an entire system to support housing areas destined to those who can afford these amenities. The migration of several types of equipment – such as shopping centers and recreation clubs – towards the private sector demonstrates its higher efficiency when it comes to understanding the several demands of the Brazilian population and making compatible responses feasible, when compared to the capacity of the State to manage such initiatives. Such incapacity is recognized by the Government Authorities itself when it permits the management in a condominium regime of areas that should be under its own responsibility.

Even when some open spaces resulting from a disperse occupation are incorporated to mingle with the compact city, many of them remain with no specific destination for an undetermined period (Campos, 2008). This fact reinforces the importance of understanding the role played by these spaces and the potentials they have when it comes to consolidating new forms of urbanization.

Even though this constitutes an essential phenomenon for the understanding of contemporary urban dynamics, a prejudicial vision on the subject still prevails among many Brazilian technicians. The proposals made on this matter usually consist of the application of proven solutions to the compact city, whose effects on the specificities of disperse urbanization are questionable (Limonad, 2007).

²⁹² This new condition is demonstrated by the creation in 2010, by the Brazilian Institute of Geography and Statistics (IBGE) of a range with seven transition categories of what is defined as rural and urban.

²⁹³ PROST apud Panerai, 2006, p. 22

At the same time, the Brazilian government incentives the national automotive industry by means of investments and expressive tax exemption, which usually ensures the constant increase in the production of automobiles²⁹⁴ and turn automotive vehicles into the main means of transportation in the country.

In this context, the creation of disperse urban centers on the outskirts of metropolitan areas of major capitals presents a contradictory relationship that is particularly interesting for the development of this work: the non-urbanized spaces generated by urban sprawl are fragmented, but at the same time they have enabled the unintentional preservation of an expressively amount of ecologically significant areas.

The West Portion of the Metropolitan Area of São Paulo

The area is characterized by a hilly plateau, with expressive hydrography and portions of dense Atlantic Forest, usually of primary growth. It is structured by three major road axes – highways Régis Bittencourt (connection with southern Brazil), Castelo Branco and Raposo Tavares (connections with the west of the state of São Paulo), and the west portion of Rodoanel (the local ring road), which connects the three other axes. This region comprehends the municipalities of Barueri, Cotia, Embu, Itapecerica da Serra, Itapevi, Santana de Parnaíba, and Vargem Grande Paulista, as well as the municipalities of Carapicuíba, Osasco, Taboão da Serra, and part of São Paulo (Figure 2). The latter four have not undergone a process of urban sprawl – opposite to the others – but have experienced a compact, continuous urbanization that connects them to each other. The non-urbanized areas also include several segments with small rural estates.

The population growth in the Vector started in the 70's, when the Metropolitan Area of São Paulo (*Região Metropolitana de São Paulo* - RMSP) started to receive migrants mostly from the Northeast region of Brazil. The group of municipalities in the West Portion with disperse urbanization occupies a total area of approximately 970 km² and, in 2012, held a population of approximately 1.7 million inhabitants, according to the data from State System Foundation for Data Analysis (SEADE).

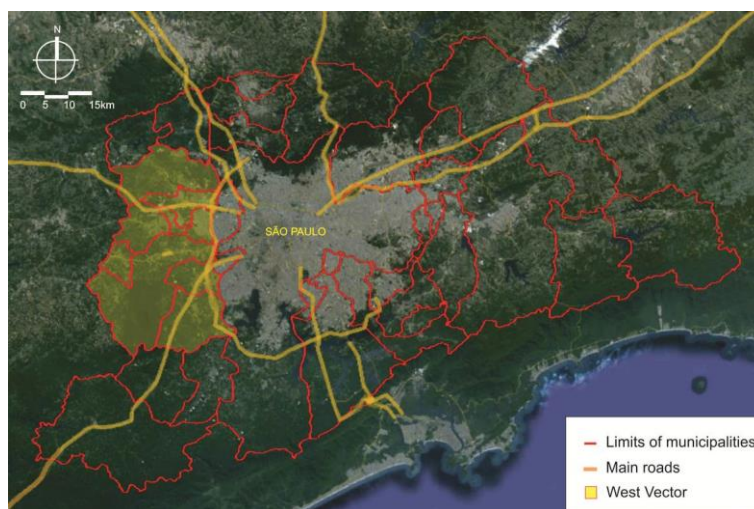

Figure 2. Western Portion of the RMSP. Source: Author's drawing based on images from Google Earth, 2013.

²⁹⁴ According to the ANFAVEA, the production of vehicles in Brazil in 2013 totalled 3.74 million vehicles, which sets an annual record in Brazil. In November 2013, Brazil was the 5th largest producer of vehicles in the world, according to data from Jato Dynamics.

Figure 3. Urban fabrics in the Western Portion of the RMSP. Source: Author's drawing based on images from Google Earth, 2013.

Sprawl in the West Portion

In the segment under study, the sprawl is comprised of the following urban fabrics, based on the subdivision established by the researchers of Quapa SEL Project:

Large Structures

Sectors with predominance of warehouses with several purposes – industry and logistics, corporate condominiums, and large shopping/recreation centers – with low-rise aspect and up to three stories (Figure 4). Most of them are located along the axes of highways Castelo Branco, Raposo Tavares, Régis Bittencourt, and Rodoanel, and in lower numbers in side roads.

As for the clustering type, they are organized in condominiums or in sparse clusters, configuring smaller patches. They may present an orthogonal mash road design, as in the case of developments such as Alphaville and Tamboré²⁹⁵, or an irregular road design, as found in most of the other occurrences.

²⁹⁵ Cf. Campos (2008).

Another form of organization of the urban fabric is found as industrial condominiums distributed in sparse patches, both along the major highways, such as Raposo Tavares, and along side roads.

Houses Groups

A house group (*casario*) is defined as “extensive areas occupied by housing or used for that purpose, configuring a particular and clearly identifiable landscape, both for its individual elements (buildings) and groups (fabrics)” (Carvalho, 2011, p. 96, free translation).

These are created by allotments open to public access, both formal allotments and squatters, comprised mostly of dwellings built manually by low-income populations (Figure 5). In some cases, they include small warehouses or housing projects. Due to the context of land irregularity that involves a significant part of these cases, the land occupation process takes place in a fragmented manner and according to the opportunities at hand, with many interstices left with significant green spaces. The most recurring type is comprised of elongated plots (5 x 25 m), where houses are built with no frontal or lateral offset, including a second, smaller construction at the back of the plot. There are cluster housings in smaller numbers.

This fabric is common to all municipalities in the Western Portion, configuring a vast, continuous urban patch that mingles with the municipality of São Paulo and extends through the municipalities of Carapicuíba, Barueri, Jandira, and Itapevi. This fabric also occurs significantly in the eastern portions of the municipalities of Embu das Artes and Itapeçerica da Serra.

Figure 4. Industrial and logistic warehouses along Presidente Castelo Branco highway, in the municipality of Jandira.

Figure 5. Low-rise housing in the municipality of Jandira.

Public / private housing projects

Fabric comprised of multi-family housing with three to six stories, no elevators, usually in monolithic shape or elongated “H” shape and little spacing between them. In most cases, they are built by Government Authorities initiatives (Figure 6) and by the Private Initiative (Figure 7) particularly as of the 90’s, for low-income populations. Public housing projects present undifferentiated open spaces and are usually irregularly appropriated by additional constructions with time, while private projects present some recreational structures in their open spaces. In both cases, a considerable part of the open spaces is dedicated to parking lots. These projects are usually large in size and comprised of buildings with homogeneous, repetitive volumes. In some cases, the private projects are associated with low-rise condominiums comprised of clustered houses.

These condominiums are found as sparse units along the houses groups in all municipalities. Most of the times, these projects are not developed near main roads or with better access to public transportation.

Figure 6. Housing project in the municipality of Itapevi.

Figure 7. Private housing project in the municipality of Cotia.

High-rise developments comprised of towers

These are comprised of buildings with more than six stories with elevators. They may be either residential or dedicated to commerce/services (corporate). The residential buildings include recreational open spaces with a diversified range of leisure structures. Disperse clusters are

found in the municipalities of Barueri and Santana de Parnaíba, with many of them associated with developments such as Alphaville and Tamboré.

Slums

Usually masonry buildings with up to five stories, mostly residential, built in properties to which dwellers have no titles. These buildings usually have less than 5 m in the front side and 15 m in length²⁹⁶, under the minimum dimensions defined by the Brazilian urban standards, as well as housing units with no direct access to the street. They occupy all sorts of area, most frequently those environmentally vulnerable, such as steep slopes or areas near water bodies. They are mostly located in the municipalities of Embu das Artes and Itapeverica da Serra, extending over the area that mingles with the municipality of São Paulo.

Low-rise residential condominiums

These are comprised of developments with clustered or individual houses built with the same design and in the same real estate development (Figure 8), usually on a street connected to highways or side roads. They are built on adjoining lots to gated communities and are usually oriented to families with medium and high buying power. These developments are located mostly in the municipality of Cotia.

Gated communities

These are comprised of gated allotments of different sizes, with common areas and preserved areas of different sizes, where residences or corporate developments are built by the owners of the plots (Figure 9). This type of development occupies extensive and continuous patches of urbanization over significant areas of several municipalities.

Figure 8. Low-rise condominium in the municipality of Cotia.

²⁹⁶ According to the parameters adopted by Carvalho (2011).

**Figure 9. Gated development in the municipality of Cotia.
Pictures: Leonardo Loyolla, 2012.**

Conflicts

The building types described above, added to the anthropic occupations related to open spaces²⁹⁷, have led to a series of environmental conflicts in the region, whose impacts are subdivided herein into four categories – vegetation, water, soil, and landscape –, all of which are listed in Table 1. An analysis of these conflicts demonstrates the severing of tree-covered fragments as the most recurrent impact resulting from the anthropic dynamics over natural dynamics.

Table 1. Impact of human occupation standards on the natural dynamics in the Western Portion of the RMSP.

Natural support	Impact	Precarious settlements	Open developments	Gated communities	Low-rise condominiums	Towers	Country houses and farm houses	Large Structures	Mining Areas
Vegetation	Illegal / legal deforestation	x	-	-	-	-	x	-	-
Vegetation	Severing or remaining woods	x	x	x	x	x	x	x	x
Waters	Contamination	x	-	-	-	-	x	x	x
Soils	Impervious surfaces	x	-	-	-	x	-	x	-
Soils	Destabilization	x	-	-	-	-	-	-	x
Soils	Marked disfiguration of the original topography	x	x	x	x	x	x	x	x
Soils	Contamination	x	-	-	-	-	x	x	x
Landscape	Loss/privatizing of visual relationships	x	-	x	x	x	-	x	x

²⁹⁷ The construction types now include country houses and mining areas, which, different to the other types, are spaces predominantly free of any constructions.

Natural and urban dynamics: possible interrelations?

It has been widely accepted that the disperse and fragmented urbanization process is necessarily harmful to the environment, as this not only contributes to reducing continuous green spaces that support the local fauna, but also causes the population to make an increased number of travels (and consequently, more pollution generated), as well as the recurring need to expand the urban infrastructure network.

On the other hand, the urbanization process usually leaves interstices that may be a result of the inherent interfaces with natural resources. In this sense, Peres and Polidori (2010) consider "the fragmentation of the urban form as an intrinsic aspect of the urban phenomenon that results from the morphological self-organization of the urban system in the scale of water basins" (p.9 – free translation). Said self-organization takes place by means of successive compacting – when urban fabrics reach a significant barrier, such as larger water courses or very steep terrains – and expansions – when these obstacles, for several needs, are overcome and new areas with less restrictions to urbanization are found, until a new obstacle is encountered.

The region under study herein had few physical restrictions to occupation and an ambiguous, more intense process took place, which weakened its environmentally significant areas through successive reductions in the sizes of its wooded coverage and their interconnections, while, on the other hand, the fragmented, disperse urbanization assisted in the preservation of these areas.

In view of the ambiguity of this process, the dispersion may represent the starting point to a more suitable urban occupation standard, provided that: i) environmentally significant open spaces are maintained in between urban occupations; ii) connections between these areas and natural resources are established; iii) the density of urban areas is increased with the respective and appropriate development of infrastructure in order to minimize the need for local populations to commute.

Thus, the urban existence with physical dispersion is not considered a problem in itself, but a process that generates an opportunity for environmental preservation and urban quality that can no longer be wasted. The problem lies in the functional dispersion and in the fragmentation of open spaces with significant natural resources without the necessary connections, which should be made by means of appropriate urban and sanitation measures.

Possibilities

Several mechanisms may contribute to improve the interactions between environmentally significant resources and urban areas. In this regard, the study developed by Forman & Collinge (1997) outstands for demonstrating that, when compared with the random removal of vegetation, the application of a localized urban occupation planning combined with environmentally fragile areas may increase in five times the level of protection to these areas.

As a measure to minimize the impacts of the disperse urbanization, Peres and Polidori (2010) indicate the creation of compact urban poles with higher self-sufficiency from all other built areas in the surroundings, so as to reduce the constant need for travels.

Non-urban, environmentally fragile areas need to be dependent on each other, and proper connections that ensure the maintenance and survival of biodiversity must be provided, as Forman (2014) indicates in his work.

Czamanski (2008, p. 324) proposes an approach that unifies both situations described above. By establishing peri-urban areas as one of the three main land use categories (along with urban and rural uses), he suggests possible and less conflicting interactions between the city and nature. However, he indicates in a more restricted way that said situation would be more likely to function properly in high-income areas and suburbs similar to those in North America.

As a complement to the provision of interconnections between natural and urban areas, mechanisms promoted by the Government Authorities should exist to prevent the isolation of

extensive gated urban portions, as this is a recurring problem in several new urban areas in Brazil.

In this sense, and in the Brazilian case, for instance, the size of gated communities should be limited, or larger interfaces with such developments with the surroundings should be required by means of mechanisms other than walls and fences, such as the fostering of the occupation of their perimeters by other uses open to the surrounding streets.

The definition of natural areas under the responsibility of the private initiative is also indicated as a possibility. This is based on the principle that the private initiative has better means to maintain environmentally significant areas in the form of Private Natural Heritage Reserves²⁹⁸, or biological reserves. In developments oriented to higher income populations, the future owners have sufficient resources to incur higher land prices in order to maintain environmentally fragile areas unoccupied, according to the idea of better quality of life. This mechanism is also used by developers as a sales statement implied in the concept of “living closer to nature”, which is encouraged by the restrictions imposed by the environmental legislation, even though still slowly and gradually.

The occupation density of urban settlements establishes a direct relationship with the proposals of alternative interfaces between natural resources and urban areas. Arendt (1996) argues that the urbanization model based on large plots may be harmful to the existing natural resources, as it fragments them inside different estates. The result of this urbanization model can be easily observed in high-income patches that exist today in the Western Portion, such as Granja Viana, for instance. The significant wooded areas are gradually subtracted by means of the occupation of each plot, and the result of these allotments tends to be very similar to the conventional neighborhoods of the compact city (Figure 10).

Figure 10. Granja Viana – Cotia – SP. Picture: Leonardo Loyolla, 2013.

The author suggests that areas containing significant natural resources should be shared by residents as common areas. This logic may show to be feasible in countries where the culture of sharing woods and wooded areas is already in place, such as the United States, but a similar implementation faces evident difficulties in the Brazilian reality, which is characterized by the abandonment and degradation of environmental preservation areas.

Recent experiences in the Western Portion have worked better with this issue, as exemplified by the developments of Alphaville Burle Marx (Figure 11) and Granja Viana (Figure 12), which incorporate significant masses of wooded areas inside and outside the development to meet

²⁹⁸ Legal mechanism created by the Brazilian System of Preservation Units (*SNUC*) in the year 2000, defined as “a private area with a remarked perpetuity aspect in order to preserve the biological diversity”.

legal obligations, while, at the same time, trying to add value and use this resource as a marketing tool.

Figure 11. Gated development Alphaville Burle Marx.

Figure 12. Development Alphaville Granja Viana.

The use of occupation models based on country houses may also constitute an alternative of interface between human occupations and natural resources. This form of occupation with scarce constructions allows for larger extensions of pervious surfaces and wooded coverage within the boundaries of each plot, and are also associated with potential economic activities, such as fishing parks and weekend rentals.

Possible actions also include the reinforcement of current directives in force in the region that have not yet been effectively practiced. One outstanding directive includes the application of buffer zones, with more restrictions to the use of the soil in urbanized areas around environmental resources, so as to reduce their impacts. Moreover, it is necessary to expand the areas protected by parks and reserves by means of the full restriction to the occupation of areas with more fragile and significant natural resources.

This should also require the creation by each municipality of a system of public open spaces for recreation and preservation interconnected to each other, so as to make use of the several existing natural resources as the base for their construction.

Furthermore, the policies and directives should be defined jointly by municipalities in order to promote necessary connection between environmentally significant open spaces. This seems to be critical to accomplish the objectives stated above and has virtually not been practiced in Brazil, a situation that is made even more difficult by the chronic and current incompetence of public authorities when it comes to administration.

It is also important to enforce the consolidation of the existing urban centers and the accurate boundaries of new urban developments with the previous provision of infrastructure in these areas. That is: the advance planning of urbanization or at least its basic infrastructure – something that has rarely been done in Brazil to this date.

Considerations

Although the spatial fragmentation has contributed to the maintenance of some integrity of environmentally significant spaces in the Western Portion, the continuation of this process will bring more and more irreversible consequences. The number of open spaces created before still offers preservation opportunities that should not be wasted. To do so, the application of mechanisms different from those usually applied in this area is required. This work presents several instruments intended to demonstrate the existence of significant opportunities to establish less conflicting interfaces between urban occupations and significant natural resources in the Western Portion, as it is still possible to make good use of the disperse urbanization process in that area. However, the application of this idea requires joint actions by the several agents of transformation of these spaces in order to change the current occupation paradigms.

Integrated approaches in *Vitória* workshop: a study on open space system and the urban form in Brazil

Eneida Maria Souza Mendonça

Architecture and Urbanism Department, Arts Center, Espírito Santo Federal University, Brazil. Rua Luiz Fraga, 69 – Maruípe – Vitória – Espírito Santo – Cep: 29043-180. E-mail: eneidamendonca@gmail.com

Abstract. *This paper presents the experience regarding the workshop in the study about “Open Spaces Systems in the Formation of Contemporary Urban Form in Brazil: Vitória’s Case”. The activity is part of a national research coordinated by São Paulo University, which links a broad range of researchers from several Brazilian universities (Campos et al., 2012). The concept of open spaces originated in Magnoli’s study (1982) as the space free from construction. Urban form involves the relationship of open and built spaces—(Lamas s/d; Panerai, 1986). The workshop was coordinated by the national and local team, Vitória Nucleus of Espírito Santo Federal University. The workshop dealt with the relationship between Open Spaces and Urban form in Great Vitória, in Brazil’s southeast, and possible trends from integrated approaches involving representatives from the Government, Academics, and real estate market, addressing different scales and thematic areas. The activities were carried out in three days and had overflight and land route, lectures, group activities in themes: landscape units, morphologic patterns, legislation and the role of agents. The success of the activity was reached due to the quality and diversity of the participants, allowing achieving complex knowledge in a short time, identifying conflicts, potentialities and trends.*

Key Words: urban morphology, open spaces, workshop, integrated approaches

Introduction

Methodological Aspects

As part of the research *Open Spaces Systems in the Formation of Contemporary Urban Form in Brazil: Vitória’s Case*, the 4th VITÓRIA WORKSHOP, held from September 1st to 3rd, has contributed to the debate and understanding of the urban morphological aspects of Vitória’s region, its open spaces systems the main public and private agents performance and to the urban legislation in the configuration of this morphology and of these open spaces.

Considering open spaces the environment free from buildings (Magnoli, 1982), including streets, squares, parks, remaining areas from plots occupation, expansion areas and conservation units, the current phase of the research tries to characterize the main morphological structures of Brazilian cities’ landscape.

The research’s national coordination was done by QUAPÁ laboratory of the Architecture and Urbanism College at São Paulo University – FAUUSP –, that currently holds thirty five cities, being Vitória, Espírito Santo state capital, located Southeast of Brazil, one of them. The coordination in Vitória is done by the Architecture and Urbanism Study Nucleus of Espírito Santo Federal University – NAU/UFES –.

The 4th Vitória Workshop, coordinated by these two labs, aimed to support the research, based on an exchange of experiences arisen from distinct fields related to the city, as the academic environment, the government and real estate sector aiming to debate, under different points of view the relation between open spaces and urban form in the Greater Vitória.

Therefore, the methodology adopted followed the usual workshop procedures coordinated by QUAPÁ lab, on Open Spaces System, held for 3 days including over flights, field work, lectures and the workshop. So, during the first day there was a flight over the studied area to monitor the

occupation process and for photograph recording. On the second day, there were lectures in the morning and in the afternoon activities directly related to the workshop. On the third day there were also some lectures although the main activities were focused on workshop the works, in groups, finished at the end of the day with a presentation and a debate.

Complying with the dynamics proposed by the research's national coordination, the lecturers should draw in besides the academic world, the technical world linked to the government responsible for the urbanization and environmental preservation, real estate agents as well. Thus, lectures by professionals from state agencies were held addressing environmental aspects and large public and private projects planned for Espírito Santo, representatives of the real estate industry featuring the real estate trends in Great Vitória, professors coordinators of the national and local nucleus presenting the general framework of the research about Brazil and Vitória's region and researchers teachers dealing with the characteristics of urban expansion in Greater Vitória, including the aspects related to the current housing policy.

The workshop activities *per se*, were carried out by dividing the participants in four groups related to the following themes: urban morphology, open spaces systems, main public and private agents, and urbanistic legislature. The participants of this stage were mostly Architecture and Urbanism and Geography Msc students, Architecture and Urbanism graduating students, participants of the Scientific Initiation Program, professors and professionals of these fields linked to state and municipal agencies, besides the coordinating teams. These participants were divided into the four groups mentioned above to meet their studying interest as well as the composition diversity.

To support the activities, the coordinating teams previously elaborated certain products, made available to the participants at the workshops. The local coordination team prepared a series of maps about the studied area with information such as, the road system, urban occupation, areas of environmental concern and on each town urbanistic law. The national coordination team besides guiding the local team preparation, prepared a specific activities script to support each group's activities reflex on their specific theme, accompanied by a synthesis table to be filled. There was also available waxed paper, unlined A3 and A4 paper as well as felt pens.

The groups elaborated maps and tables, demonstrating the results of their activities presented for debate at the end of the workshop.

Before dealing with the main aspects related to urban morphology as to the open spaces system in Vitória region and of detailing methodological aspects enhancing the integrated approach in the analysis of area's urbanization process, it is proper to briefly present this field of study characterization that goes beyond the municipal boundaries.

Characterization of the study area

Vitória, the capital of Espírito Santo, is characterized as the main municipality in the metropolitan region which is composed of seven municipalities (Vitória, Vila Velha, Serra, Fundão, Cariacica, Viana e Guarapari). In Vitória there are 327.801 inhabitants, while in the metropolitan region there are 1.687.704 inhabitants, and in the state there are 3.578.067 inhabitants (IBGE, 2010).

The works done during the workshop include the city of Vitória and the capital's urban contiguity of the capital on the neighboring municipalities therefore including Vila Velha, Cariacica and Serra covering an urbanized area of approximately 1.139.807 Km² (IBGE, 2014).

The state of Espírito Santo comprehends the landscape domain characterized by the Atlantic Rainforest, with "sees of forest hills" (AB' SÁBER, 2003), whose process of deforestation and quarrying sped up in the second half of the XX Century. The field of study comprehends the region with the highest hierarchical level in the state, urbanistically speaking, while it retains important environmental areas, exposed to a conflicting dynamics and urban characterization in its preservation.

Part of the capital is in an island and part in the mainland, besides some small islands forming an archipelago and the oceanic islands of Trindade and Martins Vaz. The island of Vitória, ingrown in Vitória Bay, presents a relief composed of prominent elevations, highlighting the Central Peak and there Olhos Rock. The mainland, flat features in the northeast, a vast mangrove that expands into the municipalities of Serra and Cariacica forming Lameirão Ecological Reserve. The nearby municipalities present urban sprawl limiting landscape elements as Ecological Corridor Duas Bocas - Mestre Álvaro, that comprehends the Southeast and Northeast area, traversing the municipalities of Cariacica and Serra involving basins and ponds in Serra. The urban area follows major national roads that cut the state territory as BRs-262 e 101 and also extends along the vast coastline and its beaches, cliffs and sandbanks in the north, in Serra surpassing Reis Magos river reaching in the south the municipality of Fundão and south in Vila Velha reaching Ponta da Fruta boarding Guarapari.

Besides the federal roads mentioned above, the state road ES-010, known as Sun Road is highlighted in this study, located closer to the ocean than BR-101, plays an important role in the mobility between metropolitan downtown and all the state coastline (Map 1). Vitória, as the main town in the metropolitan region, contributes to the great number of daily trips, besides centralizing trips from nearby municipalities. This aspect contributes to the intense vehicular movement in the capital in the early morning and evening.

Figure 1. Vitória Road map.

To end this brief characterization of the field area it is appropriated to note that the region's occupation goes back to the time of the Portuguese colonization, in the XVI century only intensified in the second half of the XX century due to industrialization.

Facing this context, a diversity of urban morphologies can be seen currently, majorly due by the vast occupation history (MENDONÇA, 2013) and a diversity of balanced environmental areas, consequence of the coast, hydrographic and relief presence highlighted by rocky and forest hills. In this context of ever going urbanization conflicting with the importance of preserving areas of environmental interest, there are huge open spaces remaining of big industrial or logistic constructions, currently resulting in enclaves, which hold important potential: they stay as they are or cede space to the urban articulation integrating the occupied and open spaces in a continuous way.

A reflection on this approach was favored by crossing different points of view during the 4th Vitória Workshop, whose methodology is highlighted in the next chapters.

Integrated approaches to understand urban form and open spaces: the invitation to the lectures

The 4th Vitória workshop contribution to the understanding of the urban morphology in Vitória's region, and its connections with open spaces resulted in several factors, all consequences of the methodology used. This methodology generally introduced in the last

chapter indicates among other aspects the importance of adding distinct interests and participations to building the city. Although all methodological aspects shown have relevant contribution to the nature and content reached, this article highlights the value of enabling, in this sort of activities the integration of several, sometimes opposing, points of view to understand the proposed reality.

Keeping this in mind it is noted how fundamental it is to approach the characteristics of the invited lecturers and some elements of the content presented and debated. So it is proper to highlight that besides the careful selection of these lecturers, there was a an agreement about the theme to be dealt, taking into consideration the specialization and in some cases the notoriety of some of them in relation to the subject and the workshop theme priority considering the time frame and the success desired. Of foremost importance there as the proposed approach from the four themes and the diversity strived by the participant's distributions in their groups, linked to these themes.

Dealing first with the lecturers' approach it is possible to point in the guests selection the inclusion of professors and researchers from the national coordination, professors and researchers that do not participate in the research, real estate personnel representatives, state government officials all involved in the environment development.

The professors and researchers directly related to the research about Open Spaces Systems enlightened the participants on the theme in study and the current stage of the research.

The research's national coordination, besides general concepts on open spaces, demonstrated the spatial scope in a vast field area comprehending thirty five Brazilian cities in every region of Brazil. It was essential in this approach to clarify the importance of the research due to the fact that open spaces are in most situations the spaces left from urban occupation process and that are becoming exiguous, due to urbanization rhythm and characteristics. The approach presented by the national coordination throws a real planning perspective, open space management and acquisition in an articulated, systematic way in its several forms, in remaining areas of plot occupation or streets, squares or even enormous environment conservation areas.

It was also interesting for the work evolution the exposition of the research historical that since 2006 identified the open spaces and reflected its role in the public contemporaneous sphere an recently deals more precisely on the relation between urban morphology and open spaces. So it was fit to indicate this new theme emerged from the previous phase arisen, mostly in the studies on private open spaces and their architectural typology and soil use relationship. So when joining the studies to the open spaces the research on urban morphology widens the focus on urban life and how far urban planning should be considered.

The research local coordination's role was to present the history and its insertion in the national research indicating what has been produced in Vitória's open space system since 2006 highlighting the current stage in the research. The importance of this approach is to enable the workshop's participants to visualize the theme directly related to the field studied. This procedure allows not only to know or recall the main features of open spaces as well as sharpen the attention to the main elements to be preserved, the emerging conflicts in terms of use and occupation and the transformation potential in order to feed the debate and to provide suggestions.

Professors and researchers that do not participate in this research performed in the workshop a distinct role from those who directly act in the research. Because they were completely oblivious to the methodological procedures and results already reached, they could, within their field of expertise add important elements for reflection. The invitation was sent to two professors, one from the Architecture and Urbanism and the other from the Geography course. These were no random choices and aimed beyond the professional characteristic and themes involved. In the first case the invited professor had been for 8 years municipal secretary in the capital, having accumulated extensive experience in the city's dynamic, the planning processes and management and also about the main influent agents on this dynamic as well as on the processes. In the second case the invited professor researches and guides studies related to metropolitan expansion, approaching mainly the investigations focused on the government's

recent housing policy for people with limited income and for the current real estate phenomenon of condominiums or closed allotments. The expressivity of these ventures in characterizing the new urban outskirt or Brazilian metropolis places this issue as a special interest in the study of urban morphology. This approach has met the specific thematic recommendations of the national team, aiming to know motivations and features of this kind of manifestation on the expansion area of Greater Vitória. The first of these lecturers highlighted the important centralizing and hierarchical role of Vitória in the state, the beauty of its landscape and the intensity and versatile use of its public spaces despite the persistent academic criticism that claims otherwise. At the same time it drew the attention to Vitória's dependence to the other centralities which contributes to restrict opportunities and to export knowledge. However, the keynote of the approach guides to the importance of the places potential and in this case of Vitória to favor the happiness of who lives there. The second lecturer drew attention to the severe land ownership issue in Brazilian middle and metropolis cities, from the performance of the real estate industry in capturing land income, highlighting the monopoly income which has exacerbated the appreciation of the property. The lecturer pointed out that urban expansion has been happening in precarious areas from the geomorphologic point of view and advancing on rural areas that border the city limits. It highlights that in the case of Great Vitória, specifically in the municipality of Serra this kind of area is on the hands of a few landowners who have extensive areas of metropolitan importance. Another aspect questioned is the contradiction between the large number of vacant houses and the housing deficit in a smaller number and the ongoing construction of houses. It was also pointed out the continuous increase in the value per square meter, which doubled in Great Vitória between 2005 and 2012. When dealing with the current housing policy in Brazil, mentioning the Federal Government Program called My House My Life, the professor indicates that all units in Espírito Santo, the majority is in the Metropolitan Region of Greater Vitoria, and that in Serra there isn't any enterprise aimed at up to three minimum wage salaries. Thus, it emphasizes the appreciation of the land in this municipality and the typology of these ventures similar to condominiums or closed allotments that have also shown preference for this site with guard houses, monitoring cameras, private security etc. The lecturer sees this kind of project as something far from the city meaning, in its full meaning and makes a point to investigate the main agents of this urbanization process involving the State, real estate set, land or construction value capturers.

In contrast to this approach, the invitation to the representative of the real estate business was sent to the vice-director of the Industries Federation in Espírito Santo – FINDES –, an entrepreneur of the Civil construction with extensive experience in participating municipal councils focused in urban decisions in Greater Vitoria. The lecturer highlights initially FINDES investment in education and points out the federation interest in the urban mobility theme. The lecturer also said not always keeping buildings with few floors contributes to the open spaces system, preaching about the opportunity to create open spaces as buildings go vertical thus reducing the occupancy rate.

Among the real estate trends in Greater Vitória, the construction of seven shopping centers was the highlight demanding an urban mobility project.

Mentioning developments in the four municipalities that make up for the main urban core of Greater Vitória, some highlights were presented. The promising gaze of the market is aimed at Vila Velha and Cariacica that besides shopping centers present prospects for investments in condos for different income levels including My House My Life. In Vila Velha this emphasis is aimed at Terra Vermelha region. In Cariacica there is the expectation in the closing of CEASA's installations, generating new real estate opportunities and work on Kleber Andrade stadium, that will host the training of international teams during the World Cup in 2014. In Vitória, Jardim Camburi boarding Serra was introduced as the largest construction site in the city; there is also mention of Enseada do Suá surrounding the shopping center and the technological center planned for Goiabeiras. In Serra it was emphasized the building of the downtown in Civit avenue, of a trading and college center in Portal de Manginhos and Alphaville condominium.

The invitation to the state government representative was sent to the Jones Santos Neves Institution directors, a research government agency in Espírito Santo State, position held at the time by a geographer and Architecture and Urbanism Master. The data presented refer to the investments planned for the state in the period 2012-2017, with 57% directed to infrastructure, especially energy, oil and gas, 27% to industry and 3.7% to construction. The speaker notes that 26% of these investments refers to the metropolitan region and draws attention for the south coast region scheduled to receive 42.3% of the investments. He highlights the concentration of GDP in the metropolitan area, corresponding to 63% and observes the economic characteristic of the current period related to the base of the oil and gas chain indicating the importance of relating this process to improving the quality of life of the population.

Representing the state point of view linked to the environment the invitation was sent a employee of the state agency, that has just finished the Masters in Architecture and Urban Planning, studying the prospects for transformation in the land use in the State south coast because of the planning of installing large equipments. The speaker gave prominence to the existing areas of environmental interest in the studied field composed by the four cities in question, Vitória, Vila Velha, Cariacica and Serra watching the importance of planning urban development in the most urbanized region in the state in line with the preservation of the environment. In this context are located and presented images of various Environmental Protection Areas, National Parks, Reserves and Ecological Stations, which in some cases cover areas of several municipalities. Since these approaches appear to support the practical workshop activities, it is noted from the methodological point of view of the invitations made to key people with the strategic knowledge on the subject and in many cases critical thinking on the issue, depending on academic training, even before the institutional representation. In summary, these various approaches indicated the growing urban and economical vitality of Greater Victoria and the State of Espírito Santo region and the challenge of reconciling the exploitation of natural resources with the preservation of valuable environments from the natural point of view, and the generation of social benefits to the population. It was also possible to notice the fundamental importance of land ownership

In the speculative context of ongoing activities and the expansion of real estate appreciation beyond the capital, covering the immediately surrounding municipalities.

From these results it is possible to also monitor, some interpretations articulated from the products carried out by the work groups, confirming the validity of the integration of participants from diverse backgrounds.

Integrated approaches to understand urban form and open spaces: The invitation to the participants

The invitation to the workshop participants was similar to the procedure carried out to the lecturers, aimed at specific professionals to comprehend qualified performances and a diversity balance in the number of guests involved.

The quality of performance was achieved by the selection of professionals that somehow act or acted on the theme in question. The identification of these professionals was conducted by the local coordination of the research, considering previous involvement with them or participation on the subject, acknowledged publicly. The diversity of areas and number of people involved were also controlled by the local coordination. The areas involved are linked to Architecture and Urbanism, Geography and Environment, with some specializations focused on design of public spaces, environmental preservation, landscaping, planning law, urban development, real estate dynamics, physical geography, human geography, spatial segregation, among others. Besides the diversity of practices, diversity of professional roles among the participants was sought. Thus, as to the academic environment, the invitation was addressed to professors, graduate and undergraduate students the latter linked to the Science initiation research, as for municipal agencies we attempted to involve the technicians from urban

development and environment agency as to state agencies the guests were related to two institutions, on linked to research - Instituto Jones dos Santos Neves – and the other to the environment - Instituto Estadual de Meio Ambiente e Recursos Hídricos – IEMA –. As to the municipal agencies, due to the coverage area attempts to receive professionals engaged in the four municipalities were done. However, the possibilities of participation occurred only by officials of the municipalities of Vitória and Serra. To aggregate knowledge about the remaining municipalities, some strategies have been used, such as direct invitation to professionals who had already worked in similar areas of the workshop in Vila Velha and Cariacica Town Hall. The organization of prior workshops, the professional experience of the local coordination in activities directed to the urban development in Greater Vitória and the interest of these determined professionals in the academic research and post graduation, even without a formal connection to the University, contributed for the welcoming of the invitation.

The control on the number of participants was done by asking guests to RSVP in a certain deadline. This strategy helped to check the necessity of broadening or diversify the invitations. Also taking into account that municipal and state technicians, by function are not always available during the workshop the invitation tried to reinforce the importance of full participation to those who accept the invitation.

The amount indicated by the national coordination was of about 40 participants. In 4th Vitoria Workshop, 36 people attended and 30 participated assiduously. These 30 participants were divided into four groups, in order to combine their fields of interest and the always longed diversity training, involving the following issues: 1 - The open space in the constitution of landscape units, 2 - The open space in the constitution of morphological standards, 3 – Proposed forms by the law (open and built areas) and 4 - The actual role of agents of production of open and built spaces. Thus, the groups ranged from nine to six participants, adding to these, coordination personnel equitably distributed with the role of feeding the debate and guiding the activities to be developed, based on pre-arranged script. The activities were carried out so that each group during the debate would define in map and table aspects for each topic related to the area of Vitoria, by oral presentation at the end of the last day of activities. Based on the technical quality and diversity of participants was possible to understand the main characteristics of the study area regarding the aforementioned topics. The maps were hand-drawn (Figure 2) for subsequent digitization (Figure 3).

Figure 2. Group 1 Map on landscape units.

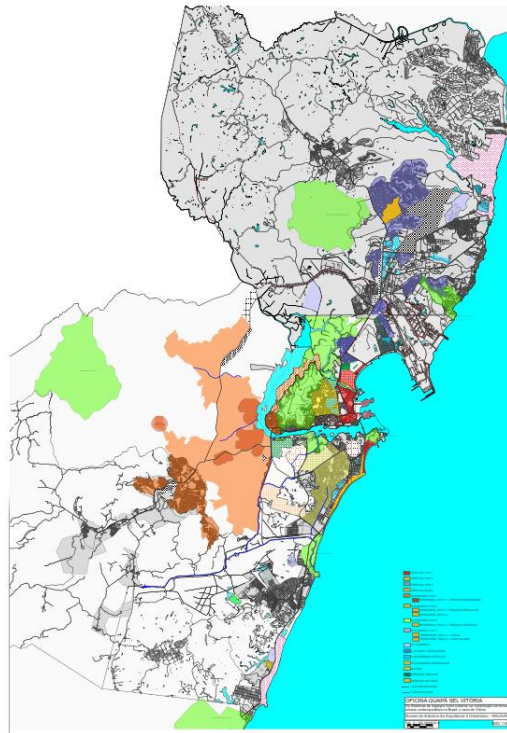

Figure 3. Group 2 Map on Morphological standards.

The exception occurred on the initiative of the group on the study of urban laws, that produced during the workshop, the georeferenced map (Figure 4) and constructive models scanned in three dimensions (Figures 5, 6, 7 and 8).

Thus, the groups that have studied the landscape units, the morphological patterns and the main agents acting on space, sought to encompass the entire territory subdividing it according to the situations considered homogeneous. The group that studied the urban legislation defined areas of study to cover the four municipalities and distinct situations as to the possibilities of land occupation, such as areas of intense interest in real estate and coastal areas, as demonstrated with respect to the municipality of Serra respectively in figures 5, 6 , 7 and 8.

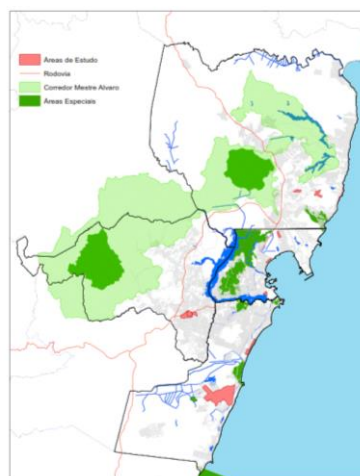

Figure 4. Group 3 map on Urban Legislation.

Figure 5. Deployment and maximum volumetric for Av. Civit, Serra, ES.

Figure 6. Deployment and maximum volumetric for Av. Civit, Serra, ES.

Figure 7. Deployment and maximum volumetric in Manguinhos, Serra, ES.

Figure 8. Deployment and maximum volumetric in Manguinhos, Serra, ES.

During the presentation of the work, the national coordination proceeded to a series of notes and graphical illustrations so that at the end it would present a summary its apprehension about the reality in study, from the workshop held. In this synthesis, the national coordination has highlighted the aspects considered special, provoking debate and pointing peculiarities perceived on the study area.

Among the issues raised for discussion the most striking were the morphological diversity of the region and the intensity of interest in real estate expansion along the coast and nearby areas of environmental interest. It was further observed that the dominance on the coast refers to the vertical format construction while in other areas of environment interest prevail single or multifamily condominiums or closed allotments for population of high, middle and low income.

The strategy to provide in each group, a scientific initiation scholarship student, a graduate student in Architecture and Urbanism, allowed them an advanced learning by the opportunity to participate in qualified debates on their respective fields of study. The benefit to the participants of the workshop was the possibility that these students could act later in digitization and printing preparation of the workshop final report. The integration of in these same groups of postgraduate students made possible, besides the learning acquired throughout the activity, their

counterpart in the organization of the preliminary reports on each theme. All these methodological and practical aspects contributed to the debate about the urban and environmental processes in Vitória's region and the opportunity to unfold these considerations into actions.

Final Considerations

Given the above, we can conclude the success of adopted dynamic in 4th Vitória Workshop, due to the method developed by QUAPÁ Laboratory from the School of Architecture and Urbanism at São Paulo University, national coordinator of the research and performance, articulated to this, the Nucleus for the Study of Architecture and Urbanism of the Federal University of Espírito Santo, local coordinator.

The methodology adopted, especially regarding the diversity and technical quality of the participants has provided in a fairly narrow time the grasping of general features related to open spaces and the urban form of the region of Victoria.

On the other hand, one must recognize the presence of a number of differences in the detailing of the activities of each group depending on the specific methodology established by it, the dynamics of the debate and also the personal characteristics and the ability of mingling of each participant in the group.

These aspects are understandable, since it was not a homogeneous group and that not all members had known each other beforehand. In any event, even considering these issues, it was possible to gather in the results, the most significant features about each theme.

As an important role in the workshop, one also considers the fact that each theme, from the discussions and the conclusions drawn, counts with an embryo of reflections, with potential to be developed in future studies.

The diversity of participants lets the unfolding of the activity in multiple actions as academic performance in research, structuring topics for dissertation and thesis development and enhancement of professional practice in public sector activity.

Anyway, the aim is the activities developed allow participants to carry forward methodology, considerations and commitments with the qualification of open spaces and urban morphology of the region of Vitória.

Brazilian Morphology

The urban form of the housing policy “Minha Casa Minha Vida” in the Metropolitan Area of São Paulo

Veronica García Donoso, Eugenio Fernandes Queiroga

Lab-QUAPÁ, FAUUSP, São Paulo, Brazil. E-mail: veronica.donoso@usp.br.

Abstract. *This work is intended to discuss some of the results of the recent Brazilian housing policy “Minha Casa Minha Vida” (PMCMV), created in 2008. This policy has been created to address housing needs over several economical fronts. This forms part of a doctorate research program developed by the QUAPA’s group of the Architecture and Urban Planning School of São Paulo University (FAUUSP). The PMCMV has been created for the first time with Brazilian housing policy in conjunction with the private sector’s participation for the construction of social housing. This production model for urban space resulted in a formal conclusion based on a decrease of the overall cost of construction. However, this also resulted in an increase on profitability for the builder whose urban form is agreed based on financial criteria and, assisting minimally with the demands of the program and the daily needs of the population. The formal result is homogeneous, besides a uneven distribution of open spaces and community areas.*

Key Words: housing policy “Minha Casa Minha Vida”, open spaces, urban form, urban space production.

Introduction

This work is part of the theme research of the Brazilian open spaces system, by the National Research Group QUAPÁ-SEL, coordinated by the Laboratory QUAPÁ, of the Faculty of Architecture and Urbanism of the University of São Paulo (FAUUSP). The actual theme project is named “The open spaces systems in the Brazilian urban form constitution: production and appropriation” (2012-2016) and presents some analyses of several Brazilian cities, looking to understand the relationship between the open spaces and the urban form.

In the theoretical approach about the open spaces is observed not only the vegetated areas, but also all spaces free from construction which are either public or private, that are part of the systemic relationship that is settled among non-constructed spaces and cooperates with environmental, visual and social relationships. Thus, those spaces are analyzed inside of an open spaces system (SEL), and the importance of those spaces goes beyond the environmental perspective since the social relationships that occurred in those spaces are mainly observed in this theoretic point of view.

The concept of SEL, frequently used in landscape Brazilian studies, steps forward the usual concept of green areas, since it considers not only the environmental function of the open spaces areas, but also and mainly, the complexity and the diversity of those open spaces, their functions and uses, and also the forms of appropriation and apprehension of those spaces by the users. (Donoso, 2011, p. 23)²⁹⁹

Some results of the doctorate research entitled “Dynamics of the contemporary real estate production and their impacts in the landscape of Latin-American cities: the case of the Metropolitan Areas of São Paulo Brazil and Santiago from Chile” are presented, which was

²⁹⁹ This quote was freely translated by the author for academics motifs.

accomplished in collaboration among the University of São Paulo and the University of Chile. The research aims to enlarge studies about the urban Latin-American landscape, and particularly of social housing production, exploring the singularities of each reality.

For this study the Brazilian case of the housing program “Minha Casa Minha Vida” (“My House My Life”) – PMCMV was selected to show how this program has stimulated the housing form in the Metropolitan Area of São Paulo (RMSP).

The Metropolitan Area of São Paulo is composed by 39 municipal districts, and has a total of 20.775.114 inhabitants (IBGE, 2013).

Figure 1. The municipal districts that compose the Metropolitan Area of São Paulo (RMSP). (source: Donoso, 2014).

It's considered that the current urban form of the social housing products is resulting not just by recent transformations in the public politics, but also, historical inheritance of politics, economical and social actions that were presented spatially both in material, social and symbolic form along the years. Thus, the historical events of the Brazilian housing politics are presented for the best understanding of the current formal results of the Program “My House My Life”.

Historical facts of the Brazilian housing politics before the emergence of the Program “My House My Life” (PMCMV)

The Brazilian housing politics was marked by several programs that were created during economic and political transitional moments and they had not presented – until the current period – a continuity of actions for the production of social housing. On the other hand, it was a starting point of debate regarding this subject.

The first important actions related to the production of social housing were made during the military dictatorship which was initiated in 1964. Before this period, the state intervention was very limited, although the need of the creation of a public politics had being already acknowledged at that time due to the fast growth of the great urban centers since 1930 (Cardoso and Aragão, 2012).

During the military government, the housing policy used to be centralized by the State with own resources for the production of popular housing since the creation of the National Bank of Housing (BNH) and financing by the Financial System of Housing (SFH). Those resources aimed to assist the formal urban workers, however, it did not resulted in a decrease of the informal housing production driven by the urban growth, but it was tactic to boost the economy and to attend part of the claims for housing.

The housing politic model practiced by the military government had authoritarian strategies to control the population; it was also aimed to get support from the popular masses and pacific movements, since there were clandestine political organizations and social movements that had appeared in the context of revolutionary fights in Latin-American countries against military regimes.

During the military regime that happened from 1964 to 1985, 4.3 million housing units were built (Bonduki, 2009) and they were located in peripheral areas. The urban drawing of those housing products didn't encourage the conviviality and interaction of social groups, due to the ruse strategic to oppress popular movements, and also it did not allow those groups to release from the sad reality of social and economic discrimination. There is, thus, a poor housing production, both in the sense of the quality of housing provided to the population and the quality of urban space created, and that, besides, it did not reduce the housing deficit, so new periods of growth of informal and precarious houses continued to happen, occupying mainly in rejected areas by the formal market.

This housing production resulted of the BNH period were based on the modernist architecture and the Athens Charter, but it was not able to adopt all of modern principles which resulted in a dissemination of unfunctional and inadequate housing units. In agreement with modernist presupposition, the land unit should be extinguished and the streets and vegetal masses would acquire a new meaning at this composition. Buildings would be organized freely in great surfaces. In that conception, open spaces area protagonists in the final formal results, since they are responsible for the connection among constructed blocks. Besides that, open spaces do not have access restriction and they are always projected for a collective use (Benvenga, 2011).

Many issues were generated when this concept was applied in social housing projects accomplished by BNH, as the Brazilian social and spatial reality is far different from the described on Athens Charter, which means it was necessary to have made adaptations to apply the modernist model in the Brazilian case. However, it did not occurred at that time.

The simplification of the floor plant and the repetition of building blocks without criteria caused a negative alteration on the application of the modernist idea for housing production. But one of the key aspects that critically compromised the proposal was the lack of project in the open space areas, in general characterized of what was left, not part of the connection between blocks and even less as area for sociability.

Figure 2. Housing Project accomplished by Cohab and BNH, in Itaquera, São Paulo-SP, in the 1970's . (source: City Hall of São Paulo, 1979, apud Ramalhos (2013 p. 102)).

In spite of the formal poverty of the housing production in the military period, that was the result of the first housing politics in national reach created in Brazil, and that was kept articulated and centralized, which was drastically altered with the end of BNH, in 1986, and also with of the military period. That political rupture engendered an institutional disarticulation and pulverization of competences, that were before realized by BNH, and that were then sprayed to a number of public fronts.

That decentralization aided the retaking of democratization and of federal bases of the Brazilian State, which culminated with the Constitution of 1988 that distributed political authority in different government levels. Besides that, there was also the impact of the macroeconomics reforms of liberal character in the years 1990's, and the period of privatizations that proceeded, which meant alteration in the financing of the production of housing, and introduction of market mechanisms in the social housing politics (Arretche, 2002).

That period, called by after-BNH (Bonduki, 2009), presented several isolated initiatives that appeared with the decentralization, many of them associated with social movements and popular pressure in municipal governments. Those initiatives presented positive formal results, mainly associated to projects with popular participation and urban projects of slums areas, but that in general didn't make part of an articulated proposal or urban politics. Also with the end of the military dictatorship there were institutional progresses in the right to the city, with larger recognitions of citizens' right and larger performances in the fight for democratization of the access to the city.

The housing program “My House, My Life” – PMCMV

The housing policy structure in a federal level was retaken by the government of the president Luis Inacio Lula da Silva who adopted a decentralized perspective where different levels of government participate with the coordination of the Ministry of Cities.

The Ministry of Cities was created in 2003 to supply the institutional emptiness that removed the federal level of the discussion on urban politics since the end of the military regime. Their main actions were related to the democratization of the country, housing politics, sanitation and transport.

The Ministry presents a very infusive proposal for the promotion of changes and treatment of the population claims, however, the key challenge is to take the discussion to the municipalities' agenda. In spite of that, the Instruments of the Statute of the City and the performance of cities Master's Plans³⁰⁰ aided to enlarge of the discussion, and to fight against political strategies based in corruption and clientelism, that are in the root of the problem of the historical formation of the Brazilian urban space (Ferreira, 2010).

At Lula's second government which was during the financial world crisis in 2008-2009, two fundamental programs were created: the “Growth Acceleration Plan” (PAC) in 2007, and the “Program My House, My Life” (PMCMV) in 2009. Both programs had the intention of reheating the economy and to generate job through the real estate section. Thus, when the PMCMV was created there was a clear objective to leverage the economy and enable the country to step beyond the world crisis and also support a social objective of home construction and overall housing improvements.

It was announced the government's target of building one million housing units when the PMCMV was released. Although this goal seems extremely high, is not so significant for a country that had, at that time, a deficit of more than seven million housing units. (Bonduki 2009b).

Estatuto da cidade: aspectos políticos e técnicos do plano diretor. *São Paulo em Perspectiva*, 15(4), 130-135. ([http://www.scielo.br/scielo.php?script=sci_arttext&pid=S0102-88392001000400014](http://www.scielo.br/scielo.php?script=sci_arttext&pid=S0102-88392001000400014&lng=en&tlng=pt)) accessed on 5 may 2014.

The Program has a broad scope serving families from zero to ten minimum wages, and it is divided into three approaches: first, for families from zero to three minimum wages – income up to R\$1.600,00 (717,94 USD) which is called Track 1; second, for families from three to six minimum wages – income between R\$1.600,00 to R\$3.275,00 (between 717,94 and 1.469,53 USD) which is called Track 2; and the third, for families from six to ten minimum wages – income between R\$3.275,00 and R\$5.000,00 (between 1.469,53 and 2.243,56 USD)³⁰¹ which is called Track 3. In addition, the Program is structured in modalities:

- PMCMV Companies
- PMCMV Companies (Track 1 – municipalities with less than 50.000 inhabitants)
- PMCMV Entities
- PMCMV Rural Group 1, 2, 3

Regarding the Track 1 group, some peculiarities can be noted, related to the municipalities demand housing production units. There is a need of registration of the families to be attended and a public investment can be used from the Federal Budget – OGU, allocated in the Residential Lease Fund – FAR.

The Tracks 2 and 3 use resources from the Guarantee Fund for Time of Service (FGTS), and focus families with a percentage of funding and another of financing, facilitating the access to credit with low interest rate. However, in Track 2, there is also a percentage of use from the Federal Budget – OGU, which means that the public subsidy for families which concentrates the largest housing deficit also serves families with better economic conditions (up to six minimum wages).

Table 1. Characteristics of the Tracks 1, 2 and 3 of the Program “My House, My Life” (source: Donoso (2014) with data consulted in march 2014).

Track	Income	Instruments	Modalities	Source
1	Until R\$1.600,00	Almost integral subvention + beneficiary feedback	Companies/FAR Entities/FDS Municipalities with less than 50.000 inhabitants Rural Group 1	OGU
2	Between R\$1.600,00 and R\$3.275,00	Subvention + Financing	FGTS Rural Group 2	OGU + FGTS
3	Between R\$3.275,00 and R\$5.000,00	Financing	FGTS Rural Group 3	FGTS

The PMCMV in the Metropolitan Area of São Paulo (RMSP)

In the municipalities of the metropolitan area there is a significant variation between the number of inhabitants, population density, and poverty incidence. However, the number of housing units related to the Track 1 is not always aligned to the poverty incidence (Table 2).

The PMCMV Entities is a very particular modality, which exists due to the housing movements and urban reform. This modality acts similar to the Companies one, however, it is a non-profit organization that operates the Program, with citizen participation “as a shelter”. The entity is responsible for the entire process: selection of families, housing project and approval processes, construction, and also with the social inclusion.

³⁰¹ Conversions realized by the dollar quotation of 05/05/2014, where 1 dolar = 2,2286 reais.

Table 2. The PMCMV in the RMSP – Distribution of housing units contracted for Program Track 1 by municipality and relation with incidence of Poverty (source: Donoso (2014), with data from the Ministry of Cities (2014) and IBGE (2003 and 2013)).

Municipalities	Population (IBGE 2013)	Population Density (hab/km2)	Incidence of Poverty (IBGE 2003)	Number of housing units contracted for the Track 1 of the PMCMV (all modalities)

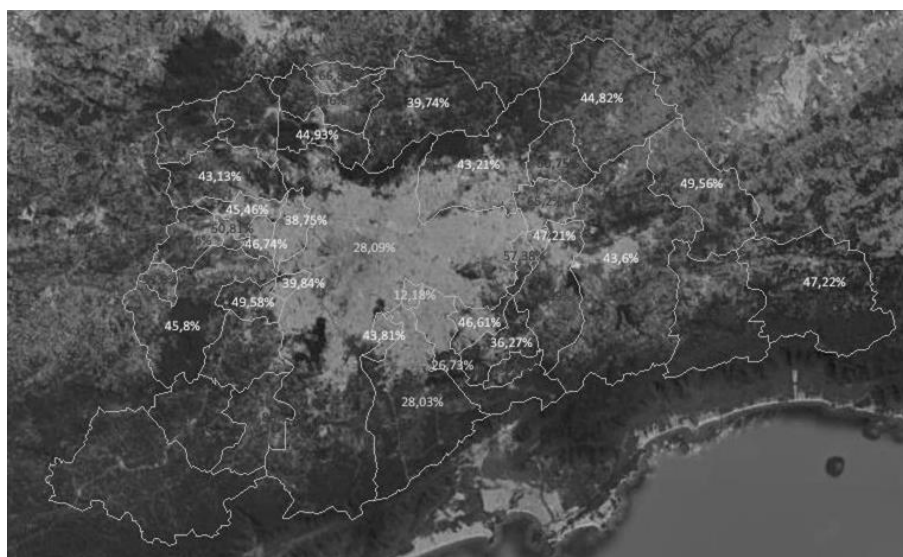

Figure 3. Incidence of poverty in the Metropolitan Area of São Paulo. (source: Donoso (2014), with data from IBGE (2003)).

The formulated policy to the PMCMV Entities assists strengthening social movements with greater involvement of the population in the process of acquisition of a home, which encourages larger notions of citizenship and also social-interest in the housing complex built.

Thus, there are more possibilities of morphological changes in projects in the Entities modalities, since the citizen participation can result in more attentive projects to the specificities of a social group, and there may be a bigger demand for open spaces projected for the family needs. However, there are just a few projects already delivered for the population in the Entities modalities for the Metropolitan Area of São Paulo (of the thirty four contracted projects, only two were delivered until the present moment), which difficult the verification of better formal results due to community participation.

Both the initiative of the PMCMV Entities and Companies, acting in Track 1, bring more hope in the fight for land access by the social group with lower income. But, unfortunately, there is a discrepancy between the conceptual policy and the realized policy, especially when is considered that it is a new and recent policy, whose results are still being realized in the territory.

One observation that can be made regarding the difficulties encountered is in relation to the land access: historically, the Brazilian urbanization process is based on the maintenance of social spatial differences, which is not easily equalized. As a result of historical differences and socio-spatial segregation has, since the military dictatorship until now, the location of social housing in urban sprawl areas, where land is cheaper. With the new housing program, unless there is a very strong intention to change this logic by the municipalities, the location will remain in remote areas, that area often without urban infrastructure.

(...) When housing decisions are dislocated to the private sector, which is what is currently happening in Brazil and what occurs in Chile since the period of dictatorship, the difficulty of dealing with the land issue, the dynamics of housing market and the value of the urban land are increased. The land issue is a major obstacle to the achievement of social housing, because if there is no public land donation or use of a well located land from the land banking of the real estate company, it won't be possible to enable construction of social housing in well located and valued urban areas. (Donoso, 2013, 0. 110).³⁰²

³⁰² This quote was freely translated by the author for academics motifs.

This logic can be modified with the donation of well located public land for the social housing construction, or with the willingness of entrepreneurs to make possible a development well located. However, it is not what recent data collected show: a map of all approved projects of the PMCMV Track 1 in the Metropolitan Area of São Paulo (some already built, others in construction) showed the continuity of the peripheral location of social housing (image 4).

Table 3. Active modalities for the Track 1 in the PMCMV (source: Donoso (2014), with data from march 2014).

Modality	Source of funds	Operation Bank	Amount of the housing unit ³⁰³	Payment by the beneficiary ⁵	Particularities
Companies/FAR Municipalities with more than 50.000 inhabitants	Residential Lease Fund – FAR	Caixa and Banco do Brasil	R\$ 54.000,00 a 76.000,00 (\$24.355 USD to \$34.277 USD) (variation according to region)	5% of the family income, with payment during 10 years, with minimum quote of R\$25,00 (\$11 USD)	Families are indicated for the Program by the municipality.
Companies/FAR Municipalities with less than 50.000 inhabitants	Residential Lease Fund – FAR	Caixa and Banco do Brasil	R\$35.000,00 (\$15.785 USD)	5% of the family income, with payment during 10 years, with minimum quote of R\$25,00 (\$11 USD)	Families are indicated for the Program by the municipality. Municipal contribution is obligatory.
Entities/FDS	Social Development Fund – FDS	Caixa	R\$ 54.000,00 a 76.000,00 (\$24.355 USD to \$34.277 USD) (variation according to region)	5% of the family income, with payment during 10 years, with minimum quote of R\$25,00 (\$11 USD)	Entities are responsible for: selection of families, project and construction.
Rural Group 1	OGU and FGTS	Caixa and Banco do Brasil	R\$ 28.500,00 (\$12.854 USD) (for the construction) R\$ 17.200,00 (\$7.757 USD) (renovation)	4% of the housing unit amount, paid in 4 annual quotes	Entities are responsible for: organizing the demand, project, construction attendance.

³⁰³ Conversions realized by the dollar quotation of 12/05/2014, where 1 dolar = 2,22 reais.

Figure 4. Distribution of approved projects of the PMCMV Track 1 in the Metropolitan Area of São Paulo (Modalities: Companies, FAR and Entities). (source: Donoso (2014), with data from the Ministry of Cities (2014)).

As mentioned, the program sets a maximum value for the housing unit in each attended Track. This unit value considers both the value of the construction as the value of the land. Thus, if there is no public donation of a well located land for the construction of the housing development, it will be relegated to an area with lower cost land. In the *Companies* modality, entrepreneurs need to decrease the value of the land to enable improvements in housing construction, and to increase profit he needs to decrease the value of both.

Entities modality has to fight against the market logic to find better located land and enable the housing development. There is clearly a dispute over land in the Metropolitan Area of São Paulo, and builders and developers step forward social movements in land acquisition. Mapping the developments of PMCMV *Entities* also shows the concentration of them in urban fringes, and in many analyzed cases there is also a lack of city (Lago, 2011).

Besides, there is also a challenge for the municipalities to regulate and control urban expansion processes and work with pressure to facilitate real estate actions that benefits the speculative capital.

For entrepreneurs, the villain of the Program is the owner of land, mainly in the great city centers, responsible for the high price of land still available. This discourse has a double effect: legitimizes the demand to Caixa Brazilian bank for an increase in the amount of funding for the poorest population and hides the speculative practices of builders, which generate by the combination of land value - caused by the land banking in urban fringes - with the large scale production of housing for families above three wages. (Lago, 2011, p. 7).³⁰⁴

There is also need for local government to combine two demands: attend popular claims and the Program “My House, My Life”, which facilitate the creation of as many social housing developments as possible, even in questionable locations. Again, the desire of producing housing in quantity is higher than producing with quality and yield higher in producing houses than producing city. (Ferreira, 2012).

In the same logic of lowering production cost is the dramatic repetition of the housing solution, which has occurred since the BNH in the military dictatorship and, as was expected, continues to happen with PMCMV. This results in a homogeneous landscape of identical housing blocks, badly located in the city, not always well constructed, which only follow the minimum required standards in architectural and constructive terms, and that cannot go against the real estate and market laws that control urban growth.

³⁰⁴ This quote was freely translated by the author for academics motifs.

Figure 7. Location of the apartment complex Portal Flora, in the municipality of Guarulhos, realized in the modality Companies of the PMCMV Track 1. Source: Donoso (2014), with data from the Ministry of Cities (2014).

Figure 8. Apartment complex Portal Flora. (source: www.qualyfast.com.br/imoveis/residencial-portal-flora/23).

As mentioned, the PMCMV aims to boost the construction market, which means that exist a higher stimulus to build new units that renovate vacant buildings. If there were more interest in remodeling existing buildings for social housing that would be easiest to promote social housing in central areas. So far, there is only one remodeling initiative in the central area of São Paulo.

The repetition of standardized buildings with blocks or identical housing units ensconce a single function totally distinct from the urban reality of families that are relocated to those buildings. Thus, it is harder to promote appropriation and interest of maintain common open areas of the housing complex. Open areas should be positive in those projects, but ends up as no one lands that terminate with individuals invasions or even depredations.

Part of the open space invasions occurs in one story houses, or even blocks with housing units in the ground floor, and families expand their house due to lack of space, that are inadequate considering the size of most families registered in Track 1.

However, there is a very interesting dialectic between the visual homogeneity and the real heterogeneity in the housing units, since families tend to personalize particular and collective areas considering the individuals and collective needs and tastes. Thus, to consider this dialectic between homogeneity and heterogeneity it is necessary to sustain in the complexity of everyday life, seeking in the population narration the understanding of everyday activities. Therefore, it is urgent to develop popular practices together with the project and construction of housing complex, to extend the dialog with the population and use guidelines for the project conception. (Donoso, 2013, p. 114).³⁰⁵

Final considerations

With the PMCMV creation, 108 enterprises based on the *Companies* modality, 26 enterprises with FAR resources, and 34 projects based on *Entities* modality were approved until April 2014. Regarding housing units, there are 30.261 housing units approved in the *Companies* modality, 4.710 housing units with FAR resources, and 8.840 housing units in *Entities* modality, with a total of 43.811 housing units to the Track 1 in the RSMP. The number of housing units that have been delivered by April 2014 is around 7.500.

There is a clear success considering the quantity production, attending part of the social group that until then had no assistance to obtain a home. However, some reservation needs to be made, in order to enable progress in the program continuity.

Finally, the PMCMV, especially in the range from zero to three minimum wages, presents three different scales of issues that need to be discussed: the housing complex insertion in the city; the architectural quality; and the urban and architectural proposal of the complex, not continuing to repeat morphologic solutions that do not stimulate space appropriation and communitarian notions. Those scales are still issue to discuss due to the minimum exigencies of

³⁰⁵ This quote was freely translated by the author for academics motifs.

the Program, which consider mostly questions of the housing unit itself, and do not consider the social relation created in open space areas of the complex.

Open spaces system: describing the urban morphology of Vila Mariana's district

Helena Degreas, Silvio Macedo

FIAMFAAM Centro Universitário, Rua do Lago 876, 05508900, Brasil,

E-mail: hdegreas@uol.com.br, ssmduck@usp.br

Abstract. *Many analysis of urban morphology have been done and generally, they emphasize the relationship between the architecture of the buildings, urban land subdivisions and street patterns. The paper proposes another fresh perspective: to consider open spaces as a system, or better, as one of the urban infrastructures responsible of the urban morphology of human settlements.*

In Brazil in many cases during the XX century, the places where the rich and medium class citizens and sometimes poor people live their public life have been projected, organized, located and distributed from the obedience of public plans by real estate developers and state agencies. Although this adjustment provided developers to accommodate recreation areas, sidewalks and many other places to people, it also created a city with open spaces that seem to be fragments poorly located, unevenly distributes and dimensions and morphology unpredictable not always facilitating the realization of public life or even urban appropriation.

Formal and spatial typologies, the concept of functionality of open spaces associated with them and also the role of the spatial fragments created by according to on percentages laws originated by urban plans, are some of the aspects that will be presented. The paper will present a result of a research based on a , São Paulo's district known as Vila Mariana, that is a part of QUAPA-SEL- Network's research, which is developing the national research project entitled "Open spaces system in the constitution of the contemporary urban form in Brazil: production and appropriation".

Key Words: urban morphology, open spaces system, human settlements, landscape architecture

Introduction

The article aims to present the square as one of the most important public spaces in the city: a place where people can call upon to exercise idleness, exchange ideas, the most diverse gatherings, make public life.

In the city of São Paulo, the center of the metropolis of the same name, live about 12 million people, which, added to the population of the other 39 municipalities in the metropolitan spot, reach about 20 million people.

Figure 1. São Paulo view of the southwest area.. (Vera Tangari 2012)

Many arrangements occurred during the last decades creating new urban forms. All those forms and typologies were the result of the implementation of various programs, plans, and urban actions, each of them, carrying various ideologies of how public life should be. For example, the 1910 plan for a European city of Joseph-Antoine Bouvard; the plan of 1930 that suggested the crossing of various sectors of the city through avenues called Avenues Plan Prestes Maia. the plan / report of Padre Lebre, at the second half of the 1950's warning to urban problems resulting from uncontrolled creation of allotments and the uneven distribution of infrastructure and public facilities in the city. The PUB - Basic Urban Plan commissioned by Mayor Faria Lima (1960) recommended that the occupation of the central region would have high population densities and distribution of residential areas should be around this, leaving the county to provide the city with a road-reticulated network. The PDDI – Plano Diretor de Desenvolvimento Integrado during 1971 were created on Mayor Figueiredo Ferraz's administration and defined the permitted uses on urban sectors with maximum rates of constructions and lots occupation, controlling the density of buildings, the lots retreats, among others; and three other master plans. A proposal made in the administration of Mayor Mario Covas (1985), and Mayor Luiza Erundina's management (1991) and the last one in 2002 in the management of Mayor Marta Suplicy.

This work is the result of the study "The production of urban form and open space system - the qualification of the public square". It integrates the studies conducted by the research group of QUAPA SEL-II led by PHD Silvio Soares Macedo and PHD Eugenio Queiroga both professors of FAUUSP Faculdade de Arquitetura e Urbanismo da Universidade de São Paulo.

Historical aspects

In the late nineteenth century and early twentieth century, the city goes through an intense process of growth and modernization of its infrastructure. Its colonial features are transformed into European features, aligned the image of the city of São Paulo to the big cities of that time. The city was composed of a dense houses interspersed with ancient terraces intended for planting, grazing, bullfights and festivals, broad originated by the disarrangement in the organization of the streets, churchyards of chapels and churches. At this time both public areas intended for trade fairs and located in the central regions, as spaces for parks in wealthier neighbourhoods begin to be landscaped, along with the few existing plazas. The squares in the Brazilian colonial city were the heart of urban life. Celebrations, market, religious and secular festivals, water in the rivers and fountains, happened in these venues and socialization: a public life happen for many different manifestations.

Figure 2. Colonial square in Brazil. (Silvio Macedo 1999)

In a way, the concentration and the free movement of the public begin to undergo organization through the design and treatment of formal gardens, as opposed to the figure of the square where public life is spontaneous. There emerged in Brazilian imagination, the figure of the “square as public garden” with its paths sometimes meandering, landscaped flowerbeds, fountains, kiosks and gazebos.

Figure 3. Typical square of the early years of the twenty century in Brazil.(Silvio Macedo 1999).

During the twentieth century, relevant urban transformations occur profoundly changing the settings, programs and types of both public and private open spaces. New aesthetic references arise. The European cultural influence generates new needs and desires of the population leading to the introduction of other modes of use. Urban public open spaces undergo on requalification.

The aforementioned urban plans aimed for city beautifying and renovations. Hole urban sectors are demolished for the opening of streets, avenues and boulevards. Neighbourhood's garden and parks are built and Colonial Square nineteenth used as market, political demonstration area and socialization loses some of its functions. The appearance of the garden square shifts the collective public life.

The open space trade is transferred to commercial buildings, although it is still possible to find a few areas of the city, both in weekly fairs neighbourhoods, as in informal trade, which occupies the pedestrian streets of central areas invaded in part by such type of trade. Religious manifestations go into the churches, military demonstrations that took place in Largos (some kind of wide streets with regular form, a common urban type in Brazilian cities) before settled in large avenues. From the landscaping, the square becomes a major urban setting geared for recreation, walking and contemplation. Rules of etiquette and behaviour come to regulate public life in these spaces.

In the mid-twentieth, large populations begin to migrate to urban canters in search of jobs and better living conditions. The ancient city now requires extreme changes to accommodate the new residents. With the emergence of electricity, the coming of the automobile and the expansion of public transportation, boulevards and parkways replaced the ancient streets and winding pathways.

The lack of public policies designed for housing and implementation of public infrastructure to the poorest citizens led an uneven distribution of public facilities (health, education, sanitation etc.) in cities. Central areas pass to be valued more; open spaces on private property intended for recreation and contemplation are built while the city becomes denser. The public open spaces become the refuge of the resident population in the central areas.

In the mid-twentieth century, some parks are built at the expense of the remaining squares with the same character and landscaped in equal quantity.

The neighbourhood's gardens and parks

Created by Cia City in São Paulo, landscaped neighbourhoods incorporate in the design of allotment, wide sidewalks and corners widely apart forested, and also areas to set public squares: the inner court and also entrenched in the urban fabric. These planned neighbourhoods have deeply changed public life: the relationship of the street and the square with the surrounding buildings are broken.

Figure 4. Alto da Lapa a landscaped neighbourhood in São Paulo. (Silvio Macedo 2013)

In the colonial city, the surrounding buildings and doors, windows, looks, configured the squares and movements of people took place directly, free with no barriers. Already in planned neighbourhoods, the route of the street layout, the hierarchy for accommodation of public and private transport, prioritized the locomotion of the people. The location of the square can now be defined beforehand on urbanization project although its morphological structure will be set only after the construction of all the buildings around it. Now, between the square and the building, the relationship between the doors, windows, looks and movements of people happen just after crossing some barriers, among them the street and their vehicles (transit and speed) and the walls of houses and gardens. Breaks up the direct link between resident public spaces and thus breaks up the direct relationship with the square near community. The square in the modern city acquires new meanings.

Figure 5. Typical modern square in Brazil. (Silvio Macedo 2014).

In Brazil, from the mid-twentieth to its end, the city becomes populous, productive, motorized. Reigns functionalist planning: it is necessary to supply the demands of the population across the leisure, circulation, housing, and labour. The garden square intended for

contemplation and circulation shall receive a "program of activities" incorporating "active recreation" with an emphasis on sports and playgrounds.

Figure 6. Typical modern plaza in Brazil. (Silvio Macedo 2002)

Metropolises such as São Paulo, high-rise and rebuild its infrastructure especially transport (the metro), housing (housing programs for low-income) and leisure. Parks and squares appear as essential to the recreation of the entire urban population condition, becoming objects of political interest.

The population begins to increase value these spaces as a counterpoint to the vertical and condensed city. The garden square, the active and passive leisure remains, joining cultural activities with nature scenes and outdoor amphitheatres. With this, the design changes: the square is no longer just for the local citizen movement and appreciation of plants and water elements, and becomes a space, which hosts coexistence and permanence. Arise in São Paulo city a number of squares linked subway stations, especially in the central area, while many other neighbourhoods are destroyed for its passage.

Figure 7. São Bento square in São Paulo's downtown, a new pattern of square created during the construction of the subway in the city (Silvio Macedo 2012).

On the other hand, the urgent need for hierarchical organization and expansion of the road network replaces the narrow streets that prioritize avenues for the rapid movement of vehicles without barriers (no traffic lights) organizing the forms of movement: the pedestrian is born... slowly citizen leaves the scene ...

Many of the public spaces are cut by new routes, now wider, and allow greater flow of traffic. With more freedom on project design, public spaces reproduces the traditions of use and

occupation that was common in the city's past: returning vendors, fairs, exhibitions, feeding areas - all with the goal of attracting users-citizens. Returns informality to the public, in other words, squares occupied by street vendors and markets.

The squares at the beginning of XXI century go through a process of transformation. Public open spaces for the collective appropriation of the public, the majority being spaces that require formal and functional retraining so they can be appropriated by the public. Traffic areas and circulation; suffer from increased vehicle traffic, violence and lack of security, with the degradation of the environment by the lack of maintenance of these spaces by the government. During the first decade of this century is also the stage for the resumption of landscaping, this time focusing on the permeability of the soil and vegetation for maintenance of environmental quality.

Although the free markets and eventually the water spouts still remain (in older cities or possibly in distant suburbs, the act of using them to supply water to our house or go to the squares to know the latest news about politics or other issues are no longer part of our routines), as are the other media, like television and social networks.

Citizen's demand and public space

The human need to socialize is inherent in life, occurs in public space and privacy of our homes that have all the resources (water, electricity, or information not face connection to the world) to make our lives easier. One might even think that this is a situation that makes us less attend public areas, whether squares or not, getting your restricted use only a few moments of the day: whether in the form of passage, whether for recreation. As mentioned, part of the activities and tasks of everyday life migrated from space, leaving free the inland areas of a building. Public life has been transformed and occupy new public spaces and semi-public. The complexity involved in contemporary life fragmented society into specific groups when in not individuals. That is to say, that answering the diversity of interests that may occur free in open public spaces becomes a necessity if the objective is that these spaces mean something to citizen or neighbourhood or are part of the everyday life people. You can no longer keep on landscaping all squares and with it, attend the new user-citizen. In addition, you cannot call "squares", green areas by morphological, locational, formal or programmatic peculiarities that are detached from the reality of the groups to which is intended to reach. The question that arises among urban designers engaged to the definition of social space question is - what are the basic and distinct features of society or group that interests us express and accommodate? Moreover, how to achieve a program of activities and qualify landscaped sites that could host life enabling public appropriation?

Vila Mariana's squares

The article will present the results of studies on qualification of public spaces for the materialization of public life based on four categories: location, shape, treatment and appropriation.

Figure 8. Vila Mariana's general air view. Silvio Macedo 2014.

The description will ally open spaces formally named as municipal government, and were identified in our study area - the neighbourhood of Vila Mariana from the following new spatial types as identified by the city council . They are:

Type 1: Squares - sidewalks

Morphology:

Blocks formerly occupied by squares but remain with the name of the old street, although were occupied either by the city council by building public facilities such as schools and public libraries, or by the construction of buildings by private enterprise against the law. On the other hand, even, they were subject of low-income housing – public places invaded.

Figure 9. Square type 1.(Silvio Macedo 2014.)

Type 2: Widening of sidewalks

Morphology:

Several of the identified public grounds are small pieces of open spaces that are physically connected to sidewalks which are simple enlargements resulting from the construction of walls (fences) aligned or not aligned to the front of the lot. There were found (and its common in our lands, someone not find even a sidewalk) many narrow sidewalks with approximately 50 cm width, which make impracticable the walking tour. Positioned on those spaces, it can still be found numerous public facilities allocated randomly along the route.

These open spaces connect to the sidewalk and at the same time are bordering the streets and their traffic. They are the result of the front unbuilt urban lots.

Figure 10. Square type 2 (Silvio Macedo 2014).

Figure 11. Square type 2 in Vila Mariana (Helena Degreas 2014).

Type 3: “Corner-squares”

Morphology: Outer corner of a block formed by the intersection of two sidewalks. They are open small areas that relate directly to the streets (20% freeways) and connect to lot or property boundaries. About 35% of surveys conducted, show public grounds located in areas with declivities varying between rugged and steep. When it makes a kind of relationship between the proportions of width and length, usability is almost impossible.

Its existence is due to: i) the residual areas allotments; ii) the residual area of the road system, resulting from the enlargement of streets and avenues process, demolition of old blocks to build a track, etc.; iii) projected neighbourhoods taking into account principles of garden city

Figure 12. Square type 3. (Silvio Macedo 2014).

The surveys found many areas associated with four types of road: i) freeways; ii) arterial routes (usually controlled by traffic lights, with accessibility to property boundaries and secondary and accessibility to local routes, allowing transit between regions in the city.); iv) collecting roads (pathways connecting neighbourhoods that distribute local traffic, only intended for local access or restricted areas.); iv) local routes.

About 55% of these places are on the sides of roads with heavy traffic and no pedestrian crossing conditions.

Figure 13. (Silvio Macedo) “Corner-squares” varies between completely paved or totally vegetated with narrow walks predominate. They are implanted randomly all sorts of signs and equipment such as dumpsters, poles of traffic lights, lampposts, mailboxes and sporadically lowered guides warning signs for the visually impaired. The random placement of these devices makes walkability difficult and crossing streets almost impossible. When wider, “corner-square” are wooded and eventually beds with shrubs, lawns and ground covers, are eventually created, but public maintenance is poorly done. In the case of subdivisions that follow the design principles of the garden city, the corners have aesthetic value and are landscaped, wooded and flowerbeds are maintained by residents or firms whose lots are bordering to it and have a purely aesthetic function. Several of these free areas were “christened” by the municipality with the name of someone unknown to the local population, was designated square.

Type 4: “Midway and sideways Squares”

Morphology:

Open spaces with two forms: the first presents long lineal shape, narrow width and is vegetated and not connected physically with blocks. The second presents long lineal form, varying widths and is not bound by the court. Are predominantly vegetated areas, with narrow sidewalks, and do not have street furniture. We emphasize the fact that creating avenues for São Paulo took place on riverbeds, justifying the type of occupation as described above. These are physically connected between two-way vehicular and fast traffic. The squares located on the sides of freeways, maintains physical connectivity with two types of road: the express routes without possibility of crossing and the arterial route with traffic lights located in cases of vehicle crossings. Are fully vegetated areas and there complete absence of street furniture, urban equipment or facilities to citizens, there are sidewalks in their surroundings and sometimes it is rugged (30% of cases). The use for these cases is not feasible because it is a situation where the pedestrian usability should be provided in the project, with the forecast of stairways, terraces and ramps. The vegetation is the result of chance, clearly not having a formal planting project. In these areas the vegetation is planted in order to avoid, thanks to rooting, the collapse of green sidewalk beds or just to meet environmental compensation procedures for planting trees.

Figure 13. Squares type in Vila Mariana. Helena Degreas 2014.

Figure 14. Squares type in Vila Mariana. Helena Degreas 2014.

Figure 15. Type 4.(Silvio Macedo 2014).

Type 5: "Inside block squares" and entire block squares on entire

Morphology:

The public grounds are situated on flat or low-slope areas.

The survey , shows about 10% of the public grounds are located inside courts and are directly connected to lots and sidewalks, occupying at least one third of the total area (from 2 to 3000m²). In some stretches of the neighbourhood is observed squares occupying the entire area of the court with about 10000 m². They are found in predominantly residential neighbourhoods and are physically connected by sidewalks and streets for local traffic and low speed. Doors and windows have, in general, physical and visual access to the plazas. Generally all have furniture and appropriate urban equipment for the citizens in terms of recreational and leisure facilities. The vegetation is diversified, forming flowerbeds and is well maintained. Some have sculptures, fonts and are suitable to the pedestrians well arranged. They are fully utilized by local population because it was provided urban equipment for both sport fields, and areas of children's play - such as playgrounds, that enables social meeting.

Figure 16. Squares type 5. (Silvio Macedo 2014).

Figure 17. Squares type 5. (Silvio Macedo 2014).

Figure 18. Map including the five types of squares with approximated location (Helena Degreas , 2014)

Conclusion

This area of the city despite its shortcomings presented is still preferred over the other city, except for some of the richest neighbourhoods. Generally, the situation of this type of public place in the city attests to a total lack of foresight and design and the area in question generally occupied by segments until the upper middle class is in a stage of disability and poverty in relation to many of the cities of the country including some located in Greater São Paulo.

On the other hand the types found are recurrent in Brazilian city and denote the indifference of both the Government and the population regarding public squares attitude alone in the last two decades has undergone significant changes, with the recovery of public space occurred in some cities such as Curitiba, Campo Grande, Barueri, Palmas, Porto Alegre and Maceio.

Abstract. *The Urban Planning applied in São Paulo City during the last 40 years is characterized by a functionalist approach, very few aware of the structuring open spaces system and the urban forms resulting from the zoning legislation. Since the end of 2013, the São Paulo Master Plan is under revision by the City Council and discussed by the society. As a contribution, Lab QUAPÁ, the landscape laboratory of FAUUSP, proposed guidelines and strategies for the open spaces system in order to improve its qualification. Among the main topics, it was suggested the more comprehensive concept of "Municipal Open Spaces System" instead of "Municipal Green Areas System", more restrictive. Besides, plans for open spaces system and more integrated management tools on the topic are proposed seeking the control of urban form and ensuring proper public appropriation. Among them are the increasing of necessary public open spaces correlated to the population and building densities growth and the requirement of previous urban projects for all new entrepreneurships in land areas larger than 12,000 m². Moreover, the multidisciplinary approach was the basis for the proposals formulation, bringing together the landscape design, the urban planning, the morphological studies and the real estate evaluation.*

Key Words: Open space, master plan, São Paulo, density, urban projects.

Introduction

The Urban Planning conducted in the past 40 years in the city of São Paulo was generally characterized by a functionalist approach, with little attention to the (de)structuring of open space systems and to the urban forms resulting from the land use and occupation laws. Subsequent to the 1971 and 2002 Master Plans, a revision was initiated in 2013, to which the QUAPÁ Laboratory of FAU-USP has elaborated the set of proposals herein introduced.

The Master Plan of Integrated Development (PDDI, acronym in Portuguese) was instituted in 1971, and was the base for the first zoning Law of São Paulo, back in 1972. The manifested main objective was to set the balance between uses, and it was developed from the design of a grid of expressways. The design has crystallized the general trends. The most densely populated zones and the centers and corridors of activities were outlined based on the possibilities of such expressways and of the mass transit system, although in general there was an attempt to keep them one block away from the main road system, along which corridors of activities generally creating little traffic were planned.

An exclusively residential zone was established for the elites, as well as the corresponding transition zones around them. Industrial zones and three levels of more densely populated zones were defined, with maximum floor area ratio of 4, intended to comprise diversified activities: central zone, regional centers and neighborhood centers. Several special zones were foreseen, including rural zones, reurbanization areas and institutional areas with airports, clubs, universities and parks. Areas not delimited, comprising 65% of the urban area, were defined as a predominantly residential zone, with maximum floor area ratio of 2, and control of non-residential activities.

An important instrument to encourage the formation of open spaces was the adoption of the so-called Adiron formula, which conditioned the obtainment of the maximum floor area ratio (CA, in the acronym in Portuguese) to the reduction of the land plot occupation rate (TO, in the

acronym in Portuguese), resulting in high and isolated buildings in plots of land, many times with large open spaces, usually isolated by long walls.

Figure 1. Partial view of São Paulo (Source: Lab-QUAPÁ, July 2013).

Figure 2. High and isolate buildings with large private open space (Source: Lab-QUAPÁ, October 2013).

This zoning has resisted for 30 years various frustrated proposals to review the Master Plan. In that period, the increasing population density was concentrated in certain southeastern zones of the city, a region of upscale residences. Few planned expressways were actually executed, and a reasonably efficient mass transit system was also not implemented. The car-centric functionalist approach gave no attention at all to structuring an open space system, which ended up being addressed separately in land plots, with no urban articulation. The city form structuring was essentially defined by the provisions of the zoning law, which has not taken into consideration at all the relief and the water base of the municipality, only providing for the control of floor area ratios in the areas occupied by the elites and in their immediate surroundings.

In 2002, the new Strategic Master Plan was approved, and in 2004 the new law organizing the land use and occupation was approved. The main objectives were to restrict the population exodus from central areas, preventing the peripheral growth in environmentally fragile areas with no infrastructure, promoting the creation of jobs near workers' residences, reducing the impact on the general traffic of people commuting from the outskirts to jobs downtown and backward (pendular mobility), and above all redirecting the population density increase to intermediary areas of the city, which have good infrastructure, and to old industrial areas that would be the object of urban operations. Population density increase would be restricted in the southwestern region, wealthier, regarded as saturated, and in the outskirts provided with insufficient infrastructure.

Despite the real estate boom of the following years, there was actually a partial restriction of the population density increase in the southwestern zone. The population density increase of the intermediary zone and of the old industrial zones did not take place as much as expected, because for the first one a stock of built area was created and then depleted, contradictorily having that guideline; on the other hand, in the old industrial zones, few urban operations were actually regulated, restricting the effectiveness of the guideline for the population density increase. The outskirts and cities around São Paulo ended up having their population density increased, opposed to the proposal³⁰⁶. At last, there was a huge expansion of club-condominiums, vertical condominiums comprised of various towers in large pieces of land with fenced open spaces.

Again, the functional objectives have relegated the open space system structuring to an isolated treatment in land plots, by the land use and occupation ordering legislation.

In 2014, the new Master Plan being discussed in the City Council partially reformulates those objectives: restrict the peripheral growth, reduce the impact of people's commuting from the outskirts to jobs downtown and backward through the promotion of jobs created near their residences, and production of residences in more central regions or near the structural mass transit system. It is proposed to increase the population density, with CA up to 4, in the surroundings of main mass transit corridors – subway, railway, monorails, bus corridors, and in old industrial areas. In the pockets formed in between corridors, the maximum CA would be 2, with buildings of at most 8 stories. In the environmental protection and recuperation areas, and in areas of urban vulnerability reduction, population density increase would be controlled.

Notes on the proposal of revision of São Paulo Master Plan

In 2013, the Municipal Secretariat of Urban Development – SMDU – of the Municipal Prefecture of São Paulo sent to São Paulo City Council a Bill (PL 688/13) stipulating provisions for the Revision of the Strategic Master Plan – PDE, of the Municipality of São Paulo.³⁰⁷ PL 688/13 more than merely revising the PDE in force, dated back to 2002, effectively proposes a new PDE for the municipality. It is a much broader proposal, with more than 170 articles, to a

³⁰⁶ Meyer et al 2013.

³⁰⁷ See Prefeitura Municipal de São Paulo (2013).

certain extent resulting from the attempt to observe countless contributions from the civil society given in the public hearings that, until the date of this paper completion (May 2014), were still in progress.

It is interesting to highlight the most structural issues of the PDE Revision proposal in regard to open spaces and urban form, which are the subject of this paper. As for the open space system, the 2002 PDE states the importance of the structural water network of the city as the main factor to be considered to propose new public open spaces for leisure and for the containment of rainfall water. In fact, the water network guided public management actions from 2002 to 2012, such as the goal to execute 100 parks in the city of São Paulo and the construction of “piscinões” (big water containment pools)³⁰⁸, although, in view of the flooding problems affecting the city during the rainy season and the demand for public open spaces for leisure, and even in view of the legal enforcement of permanent protection areas along water courses (Federal Forest Code), such initiatives were still too shy and modest.

Unfortunately, the PDE Revision proposal does not focus on the water network issue, although it mentions the need of executing linear parks along water courses. Concerning the macro-zones of environmental protection defined in the 2002 PDE, which protect significant remnants of the Rain Forest to the south and to the north of the municipality, the PL 699/13 does not make expressive amendments. On the other hand, such PL proposes the creation of a plan for the municipal green areas system – SMAV – and the plan for urban trees plantation, not mentioned in the current PDE.

As for the intentions regarding the urban form, the current PDE does not structurally address the subject, except as for the maintenance of the quality of exclusively residential neighborhoods – occupied by the elite – keeping a strict control on the land use and occupation. The PDE revision proposal, although unfortunately keeping such privileges for the elite neighborhoods, has a clear position regarding the structural aspects of the urban form of the other areas of the city: it creates regions for the increase of construction and dwelling density along mass transit corridors, as well as in old industrial areas through urban operations; it proposes that the other areas of the city do not have increase of density.

Such measures shall theoretically guide the revision of the zoning law scheduled to be conducted as soon as the PDE revision is approved. After over half a century, perhaps the administration of the biggest city of the South hemisphere will again pay attention to the urban form in a structural manner, not only being concerned with the scale of the land plot, with the indexes regulating its occupation just aiming to control the land utilization – construction density increase – and to ensure ventilation and lighting to the constructions. Guidelines for the urban landscape, for urban forms and typological standards should be proposed to contribute to the urbanity³⁰⁹.

Contributions of Lab QUAPÁ

In view of the public hearings process regarding the Bill providing for the Revision of the Strategic Master Plan of the Municipality of São Paulo, the professors and researchers of the Landscape Panorama Laboratory of São Paulo University School of Architecture and Urbanism – Lab QUAPÁ – FAUUSP, aiming to contribute to enhance such important piece of the municipal space planning, have proposed several suggestions to amend the plan presented in two subitems as follows.

³⁰⁸ Popular name of rainfall water containment reservoirs, which can be open or have a lid.

³⁰⁹ Briefly, “urbanity” is understood as the attributes – formal, functional and symbolic – of the city, or of any other portion of the urban space, capable of providing proper spaces for the life in public – general public sphere (Queiroga, 2012), thus contributing for the urban life quality. About the subject, see a rich debate in Aguiar, Netto (2012).

Lab QUAPÁ proposals comprise qualification guidelines and strategies fundamentally for the following topics: open space systems; increase of free public enjoyment spaces correlated to the increase of demographic and constructive densities; stricter control of the urban form in large scale undertakings aiming to ensure proper urbanity in the relation between private property spaces and public property spaces, and between spaces with controlled access and spaces with free access to the general public.

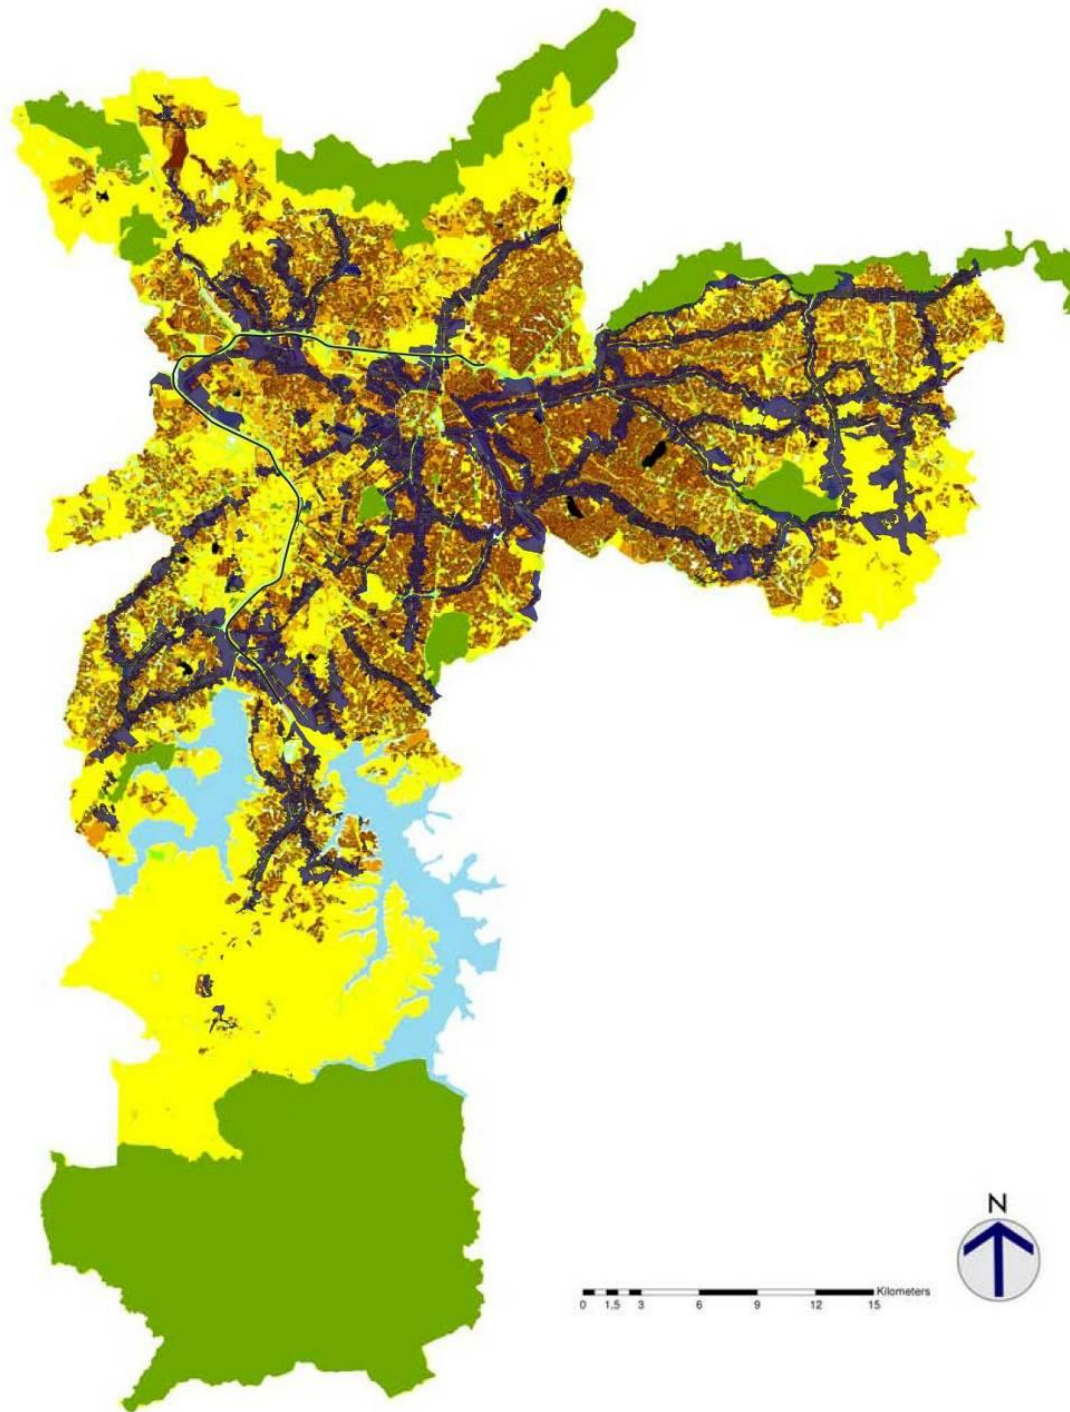

Figure 3. The dark areas correspond to areas of proposed high density, where there is little open space intra-block. The yellow areas correspond places with too much private open space (Source: Lab-QUAPÁ, November 2013).

Open space systems

Miranda Magnoli (1982) classified the open space as a space free from buildings. Open spaces are thus any spaces open to the zenith, such as streets, squares and parks, as well as backyards, open parking areas, rivers, dunes, woods, cultivated fields, etc. Upon defining the open space in such a way, Magnoli not only established an operational category, but also advocated the open space being the central object of the landscape work, considerably expanding the field of activities of landscaping in Brazil, beyond gardens, parks and green areas. With this expansion proposed by Magnoli, the city, the municipality and the region also become the object of landscaping, allowing new interfaces among landscapers, urbanists and urban and regional planners, although such dialogue between the above mentioned fields is still only a perspective, not an actual routine practice in Brazil.

Since 2006, Lab QUAPÁ³¹⁰ researches based on Magnoli's open space concept and on Morin's system (2008)³¹¹ considers that the whole city has a open space system, insofar as: every city has at least a road system, and the roads (streets, avenues, etc.) are mostly open spaces; the relations characterizing a open space system are not only environmental (open space system of environmental nature) or functional (open space system intended to social intercourse and leisure) in nature, they could be more complex, because open spaces can perform several roles, synchronically or diachronically; physical connections are not the only forms of relation between open spaces.

Therefore, the open space system of a city is not represented only by its (possible) green area system, the later is only a subsystem of the urban open space system. The open space system of a city comprises all its open spaces, either owned by a private entity or by the government, with or without vegetation, insofar every open space has attributes – environmental, functional and symbolic – which define, through human actions, a system of relations.

This theoretical reference picture, briefly summarized above, allow us to appraise and propose public policies of a broader character, less fragmented in subsectors, which is so characteristic in planning and managing big Brazilian cities. This is what was done in Lab QUAPÁ in 2013, as a contribution to the proposal of Revision of São Paulo Municipality PDE, as we describe as follows.

In the PL 688/13, the concept of municipal green area system – SMAV – is introduced as being a system encompassing all vegetated open spaces of public interest, either owned by private entities or by the government, therefore including parks, squares, forest remnants in private properties, among others. It is noteworthy that not all squares in São Paulo are vegetated, and strictly speaking they should not be considered as “green areas”, and should not be included in the SMAV. Such PL (Bill of Law) proposes the creation of a specific plan for the SMAV, aiming to preserve the environment and to qualify the above mentioned system.

Lab QUAPÁ has proposed to replace the concept of “municipal green area system – SMAV” by “municipal open space system – SMEL”, because it is clear that the SMAV is merely a subsystem of the SMEL. We understand that the term – SMAV – is limited, and is restricted to only a part of the open space system, and the later was not actually considered in its necessary coverage and complexity in the whole proposal of the PDE revision.

The Municipal Open Space System – SMEL is understood as the elements and relations that organize and structure the set of all open spaces of the municipality, both owned by private

³¹⁰ See, among others, Queiroga and Benfatti, 2007, Campos, et. al. 2012.

³¹¹ To Morin, a system is a complex object, is always a “system of systems” (Morin, 2008), is the relations of its elements, or of the attributes of its elements that define it as a system. A system has a organization given by the structural relations therein established, such relations characterize the system, so that if there are changes in those relations, the system destabilize, is extinct or a new system is created. The stability of a system structure is thus under the risk of the instability of the process that has constituted it. Such instability combines endogenous and exogenous factors to the system.

entities or by the government, including streets, squares, parks, promenades, sidewalks, bike routes, gardens, forested areas, reservoir beaches, backyards, open parking areas, agricultural use areas, soccer fields, etc., that is, all the other open spaces of the municipality of São Paulo.

Green areas are doubtless fundamental for the environmental and socio-cultural quality of the municipality, and should be understood and considered in the above mentioned systems, taking into consideration that the SMAV, for containing only part of the SMEL elements, should be replaced in the revision of the PDE by the concept of SMEL. SMAV items described in the PDE are though all fundamental, and should be incorporated to the several PDE items, in special to the SMEL.

The organization of open spaces as a system is configured as a strategy of creation, qualification and conservation of such spaces, aiming to improve the urbanistic and environmental quality of the municipality in a broader way, overcoming the sectorial view that unnecessarily fragments the actions of open space qualification in the municipality.

The following open space categories (followed by examples of corresponding types of open spaces) are part of the SMEL: environmental conservation spaces: conservation units provided for in the National System of Conservation Units – SNUC – (Municipal Natural Parks, State Parks, Environmental Protection Areas, Private Reserves of Natural Heritage, Ecological Stations, etc.) and Permanent Preservation Areas – APPs, all of them provided for and described in federal legislation; open spaces intended to social practices, such as belvederes, squares, public gardens, urban parks, promenades along waterfronts, municipal sports centers, formal or informal soccer fields, beaches at water reservoirs, open spaces in public schools, university campuses, among others; open spaces integrating vehicles and pedestrians circulation systems: streets, avenues, bike routes, pedestrian routes, flights of stairs, railways, waterways, airports, among others; open spaces associated to circulation spaces: central and lateral strips in avenues and streets, slopes besides expressways, roundabouts, gardened spaces besides cloverleaf intersections, etc.; open spaces associated to infrastructure systems: water treatment plants, waste water treatment plants, right-of-way stripe of high voltage lines, right-of-way stripes of ducts (water mains, trunk collectors, gas and oil pipelines), sanitary landfills, among others; private open spaces of collective use: parks and gardens of private foundations, clubs, corporate squares, open spaces of commercial centers, of private schools, etc.; private open spaces of residential use, single family or condominium use: backyards, gardens, recreation spaces, sports practices, etc.; other open spaces of productive or non-productive use: mineral areas, reforestation areas, agricultural and livestock husbandry production areas, fisheries, non-consolidated urban open spaces – not allotted glebes, unoccupied plots, etc.

The categories and types of open spaces of the above table are, at times, multifunctional, and form subsystems of inter-relatable open spaces. Therefore open spaces intended to social intercourse frequently also perform an important environmental role, as well as circulation spaces that can be used for social intercourse, agricultural production areas provide environmental services, etc. Such complexity requires the whole SMEL to be planned, and not only the SMAV.

For the qualification of the SMEL, the following is proposed:

A. Creation of the Municipal Plan of Parks that ensures: the creation of parks in all the city districts in a scale compatible to the population of such districts³¹²; the connectivity, when possible, through Fluvial Linear Parks and densely vegetated open spaces between Urban Nuclear Parks, Municipal Natural Parks and/or State Parks and other Environmental Conservation Units of the Municipality.

B. Creation of Regional Plans of Open Space Systems for each Sub-prefecture, harmonized with the Municipal Plan of Parks, with focus on: creation of squares and parks system intended to leisure and social intercourse, also considering their environmental contribution, ensuring the

³¹² The Municipality of São Paulo has 96 districts, with population varying between 40 thousand and 360 thousand residents, distributed in 32 sub-prefectures, and the latter have population between 200 thousand to 600 thousand residents, approximately.

distribution of such public spaces throughout the sub-prefecture territory, allowing access to all residents by foot, bike or in small routes using motor vehicles; tree planting in the urban area, in the road system, in public spaces of social intercourse and leisure, in private open spaces (big parking areas, areas with significant tree coverage, etc.) and, whenever possible, in other categories and types of open spaces above mentioned; creation of the sidewalk qualification system – expansions, accessibility, tree planting – as the main element of connection to other public open spaces; creation of open space system adequate to the mobility through bikes (bike friendly routes, bike stripes, and exclusive bike routes); articulate and potentiate the public enjoyment of the above mentioned open space categories and types whenever the urban-environmental circumstances are appropriate (except for the open spaces of restricted access – private use – and the public properties of special use incompatible with social intercourse activities).

C. In each sub-prefecture, a Department of Open Spaces Management and Maintenance shall be created, being responsible for designs, management and maintenance of all public open spaces of social intercourse and leisure (except for parks managed and maintained by the Department of Parks and Green Areas or state parks), and for the urban tree planting. The maintenance of such spaces might be object of Public-Private Partnerships – PPP.

D. Integrated structures to manage and maintain the SMEL shall be created, coordinating the actions of sub-prefectures and of the Municipal Environment Secretariat.

The SMEL shall be the object of a special regulation, associated to the land use and construction regulations, and to other urbanistic indexes and rates provided for in the PDE revision. Thus, the following sub-item of the proposal regarding the destination of public enjoyment open spaces in urban density increase areas is presented.

Urban form and public sphere

Other important contributions of the Lab QUAPÁ for São Paulo Master Plan revision address the control and induction of the private space production, aiming to define a stricter control of the urban form, and to ensure appropriate spaces for public use.

The predominant model, adopted by private undertakers, is of the building at the back part of the plot, with fenced open area and separated from the city. Therefore, the advance of high-rise buildings has been a process of cloistering private spaces, which are heavily fenced, in regard to the public ways. Thus, Lab QUAPÁ has proposed the requirement of sharing part of the open spaces for public enjoyment, for the approval of vertical projects. It is about encouraging the provision to the general public of urbanized, vegetated and equipped open spaces for public enjoyment in private land, with possibility of occupying even the spaces above underground garage floors. Therefore, the advance of high-rise buildings would be followed by the production of a network of private open spaces for public enjoyment. The treatment of such open spaces for public enjoyment should be compatible to the treatment of a square, promenade or small park, with large tree planting, leisure equipment and urban furniture appropriate for social intercourse and for the urban context in which they are included.

This proposal is particularly important for the axles of expected population density increase, along the medium and high capacity mass transit network: “Urban Transformation Structuring Axle”. This increase of high-rise buildings would be occurring exactly in the areas of the city with smaller availability of parks and squares.

For such axles, it is proposed to increase the maximum CA to 4.5 (four and a half), provided that the undertaker provides open space of public enjoyment for social intercourse and leisure with a minimum area of 900m², for plots with up to 3,000m², or 30% of the plot area, for plots with areas in excess of 3,000m². Should the undertaker not provide open space of public enjoyment, then the maximum CA would be reduced to 3.5.

In the pockets formed in between axles, as well as in the segments where the axles cross the “Urban Vulnerability Reduction” areas, of areas with environmental restrictions, where the CA is expected to be 2, the CA could be increased in 0.5 provided that

the undertaker provides open space of public enjoyment, in the same proportions and areas above defined.

Undertaking intended to social dwelling would be dismissed from such measures, aiming to optimize costs that actually allow their execution in areas well served with urban infrastructure, in particular with regard to the existence of high capacity mass transit lines.

It was also proposed the requirement of prior urbanistic designs for all undertakings in land in excess of 12,000 m², aiming to ensure a stricter control of the urban form, and proper spaces for public use. Such measures are necessary to fight the excessive cloistering of private spaces, with the fragile relation between private and public spaces, like in club-condominiums, strongly fenced and separated from the urban tissue surrounding them.

Final considerations

To formulate the Lab QUAPÁ proposals above described, the multidisciplinary treatment was fundamental, aiming to approximate the urban planning area to morphological studies, to landscaping and to real estate market studies. The internal debate about the subject, in the Lab QUAPÁ, was intense. Fortunately, we have senior researchers in the above mentioned areas. The divergence of opinions could be overcome through the common understanding that in the social production of space, the urban form, both of their constructed spaces and open spaces, either public or private, is important to qualify the city, its urbanity, its public sphere. Such contributions of the Lab QUAPÁ to the São Paulo Municipality PDE revision, although privileging the qualification of spaces for the public sphere, were always alert to the issues of biophysical support conservation in the capital city of São Paulo, also aiming to qualify environmental, or better saying, socio-environmental aspects.

Public policies towards river and streams restoration: perception and appropriation

Fany Galender, Ana Cecília de Arruda Campos

Lab-QUAPÁ, FAUUSP, Rua do Lago 876, São Paulo, Brazil 04280-000.

E-mails: fgalender@uol.com.br, anacecilia@arrudacampos.com.

Abstract. *Since the final decades of the 20th century, São Paulo's municipal government has focused its actions on treating areas adjacent to bodies of water and promoting their use through the creation of conservation parks and the reconstitution of native forests, furnishing them in order to foster urban leisure activities and sporting activities for its 11 million inhabitants. This change from a historical policy of channeling rivers and streams has occurred due to the requirements of more rigorous environmental legislation, the provision of diverse recreational and leisure areas, and, even more so, in order to fight the increasingly frequent and damaging floods that are caused by the heavy occupation of the floodplains and the indiscriminate sealing of urban soil. Policies for the implementation of linear parks along the banks of rivers, streams and reservoirs are then adopted, both for housing projects, whose priority is to relocate the populations living in geotechnical risk areas, and for projects that focus on providing leisure and recreational facilities for the population, contributing, in this way, to the recovery and conservation of the bodies of water in the urban environment.*

Key Words: *permanent conservation areas, public management, São Paulo, linear parks, bodies of water*

Introduction

The relationship between the municipality of São Paulo and its water network, including waterways, springs and reservoirs, throughout the 20th century, basically adhered to the precepts of the sanitary engineers, giving priority to the sewerage system to the detriment of any scenic and environmental potential. Usually associated with the roadway system, these works allowed for the implementation of roads along the valley floors.

In the late 1980s, there was a shift in terms of legislation, public actions and society's attitude. Of note was the implementation of the Guarapiranga Project, which later expanded into the Watersheds Program (Programa Mananciais) with the inclusion of the Billings Reservoir, reaching metropolitan coverage, and into municipal and state sphere. In the urban context, actions involving changes to the roadway system, drainage, basic sanitation, street lighting, restoration of hillsides, regularization of land ownership, and relocation of families and housing provisions, among others, initially led to the creation of public open spaces, though only incipient in the face of the needs of the resident population.

Started in 1987 and carried out by the Municipality of São Paulo, the Streams Channelization Program (Programa de Canalização de Córregos - PROCAV 1) is from that same period. In order to improve the urban drainage system, its actions involved the removal of 1590 families and the evacuation of buildings in at-risk areas in order to make the channelization of nine streams feasible and allow for the opening of avenues on the valley floors. PROCAV 2 spanned from 1994 to 2005, and despite the ongoing discussions that took place in society, it still followed these same guidelines, with the channelization of eleven streams and the creation of flood detention reservoirs, removing some 4500 families from the slums in order to proceed with the reurbanization and creation of several public squares. According to BROCANELI (2008), the second stage of the program "was an investment that did not consider urban environmental issues and/or ecosystem concepts allied to landscape ecology and environmental planning guidelines for the formation of sustainable cities, as contemplated in Agenda 21,

product of the United Nations Conference on Environment and Development (UNCED - ECO-92, Rio de Janeiro)."

The São Paulo Strategic Master Plan - PDE (Plano Diretor Estratégico de São Paulo, Municipal Law no. 13,430/ 2002), currently under review, establishes the concept of a linear park "as an element that structures urbanization, restoring the environmental logic of the Watersheds." It defines tracks of public utility throughout the waterways in order to implement green infrastructure for environmental recovery and leisure, guiding the activities of various municipal departments. Public administration focuses on drafting policies that increase the number of leisure and recreational areas for the population through the implementation of urban parks, putting emphasis on units that aim to recover areas adjacent to bodies of water, thus establishing the concept of the Linear Park.

The parks created during the 1980s and 1990s reflect a greater environmental concern because they focus not only on meeting the needs for leisure and recreation, but also on preservation and conservation – as seen in the Watersheds of the Serra da Cantareira and the Serra do Mar (BARTALINI, 1999). The parks produced in this century are more complex, since many of them are a result of urban works that sought to integrate these structures into the urban fabric, with multidisciplinary actions from various spheres of public management.

Legislation as a means of transformation

From the federal environmental legislation, the current Brazilian Forest Code (Código Florestal Brasileiro, Federal Law no. 12,727, 2012) considers Permanent Preservation Areas (Área de Preservação Permanente - APP), among others, to be the banks of any natural perennial and intermittent waterway, excluding temporary ones, from the edge of the bed's regular trough, varying according to the width of the stream or river in question, the surroundings of natural and artificial reservoirs, as well as areas surrounding springs and perennial waterholes, with a minimum radius of 50 meters (Chapter II, Section I, Article 4).

In Brazilian cities, especially in the municipality of São Paulo, we see the recurrent practice of low-income populations occupying these areas due to the absence of a comprehensive policy for the provision of housing, as well as a lack of interest in these areas from the real estate entrepreneurs.

Faced with this specific situation, there is a daily conflict between reconciling the primary destination of the APPs, that is "the environmental role of preserving water resources, landscapes, geological stability, biodiversity, gene flow of fauna and flora, soil protection, and ensuring the well-being of human populations" (CONAMA Resolution no. 369/ 2006) with much of the Brazilian urban population's basic need for housing. This initiative is considered a breakthrough in recognizing distinctions between APPs in urban and rural areas.

In this same resolution, the possibility of simultaneous preservation and human occupation was also determined (Section III, Articles 8 and 9) through the partial use of the total APP area through the public domain green areas system, permitting different percentages of impervious soil (5 %) and landscape intervention (15%), with flexibility in special zones of social interest as per specific regulations. This position will allow for appropriation and therefore the consolidation of these areas, thus producing a social and environmental gain.

From the effective occupation of these areas, the municipality's departments, mainly the Municipal Housing Department (Secretaria Municipal da Habitação -SEHAB) and the Municipal for Green and Environment Department (Secretaria do Verde e do Meio Ambiente -SVMA), formulate policies that address the APPs through actions and programs, either to create parks that are part of the public open spaces system or for the provision of housing, with the urbanization of significant sectors, thereby generating connections and environments typical of urban dynamics.

With regard to urban laws, the Strategic Master Plan of São Paulo (PDE) was developed in compliance with the City Statute (Estatuto da Cidade, Federal Law no. 10,257/2001). Therefore,

the municipalities were delegated their own land use planning by means of regulation over the usage, planning, division and occupation of urban land, thus ensuring the social functions of the city. The PDE (Art. 101) sets forth that the urbanization of municipal land is organized around nine elements, among them, the structural water network.

This "consists of streams and valley floors, the axes along which urban interventions for environmental restoration will be proposed – drainage, vegetation restoration and environmental sanitation – as laid out in the Environmental Recovery Plan for Waterways and Valley Floors (Plano de Recuperação Ambiental de Cursos d'Água e Fundos de Vale)," with the goal of developing linear parks as structuring elements of the urbanization, restoring the environmental logic of the Watersheds and defining tracks of public utility along the waterways. In Art. 106, linear parks are defined as "urban interventions that aim to give the citizens an awareness of the natural site in which they live, progressively expanding the green areas."

The Zoning Law (Lei de Zoneamento, Municipal Law no. 13,885 /2004), with supplementary regulations to the PDE, establishes categories of use under full protection, sustainable use, and special interest areas in which linear parks and greenways are located.

In the Strategic Master Plan and in the Zoning Law, the municipal planning law sets forth an improvement in the concept of linear parks as an important integrating element for urbanization, while restoring the environmental logic of the Watersheds, and defining utility tracks along different waterways.

Main public departments involved

Along with the new legislative positions, there were more partnerships between the different decision-making spheres over the economic and technical feasibility of the projects in the first decade of this century.

The Municipal Housing Department of São Paulo (SEHAB) is organized into three different Coordinating Committees: Social Service Management, Projects, Planning and Construction Program, and Land Regularization Management, and it also encompasses the Housing Company (Companhia Metropolitana de Habitação de São Paulo - COHAB) for the production of housing units through public and private agencies. SEHAB works in slums, tenements, urban settlements and housing projects, and in 2014 was responsible for the implementation of the following initiatives: Watersheds Program; the federal housing program MCMV (Minha Casa, Minha Vida); Land Regularization Program (in both the public and private spheres); Renovate SP Program (Renova SP) and Urbanization of Favelas Program (Urbanização de Favelas).

As a rule, these programs often involve the removal of residents when the homes are built in areas of geotechnical risk or where there is an inability to access the main urban public infrastructure networks such as the water supply, sewerage, lighting, etc. Secondly, housing units may also be removed in order to carry out an urban design project or for altering the roadways system. The issue of removing these populations is always controversial, often leading to the mobilization of the residents and intense discussions during the project's implementation.

The Watersheds Program aims to recover the water from the Guarapiranga and Billings reservoirs and maintain their quality, to improve the living conditions of the residents, and to ensure the social inclusion of the population and sustainability of the program's urban projects. It looks particularly into tackling broad urban issues, along with the construction of homes, which also often involves other municipalities. Additional actions include the implementation of water and sewerage networks, storm water and stream drainage, garbage collection, road improvements for vehicles and pedestrians, the paving and opening of streets and alleys, the elimination of risky areas, street lighting, the creation of recreational areas and community centers, resettlement of families, construction of housing units, social assistance to residents, and land ownership regularization, always complying with the specific laws for protection and recovery of the Guarapiranga and Billings Reservoirs.

In 2009, the Municipal Fund for Environmental Sanitation and Infrastructure (Fundo Municipal de Saneamento Ambiental e Infraestrutura - FMSAI) was created to support and fund basic environmental sanitation actions, as well as municipality infrastructure, with funds from transfers by the Basic Sanitation Company of the State of São Paulo (Companhia do Saneamento Básico do Estado de São Paulo - SABESP).

The Municipal for Green and Environment Department (SVMA) was created in 1993 through the transfer of the Department of Parks and Green Areas (Departamento de Parques e Áreas Verdes - DEPAVE), previously part of the Department of Services and Constructions. It is responsible for the implementation and management of parks. The projects planning is the responsibility of the Department of Planning (DEPLAN), and the actions for the implementation and management of the parks are the responsibility of DEPAVE, whose responsibilities also include project design, managing the construction works and services for both the construction and landscape implementation of urban parks, linear parks, nature parks, squares, gardens and other public places. Other duties include planting seedlings, surveying birds and proposing guidelines for their preservation, as well as the establishment of the Environmental Commitment Terms (Termos de Compromisso Ambiental - TCAs) for the maintenance and management of parks.

Carried out by SVMA, the 100 Parks Program (Programa 100 Parques) was implemented in 2008 and aimed at creating a set of types of open spaces that meet landscape, ecological-environmental, leisure and sociability needs, according to Arch. Luciana Takaesu. This included the Linear Parks Program. Some of the goals of the 100 Parks Program were providing a database of public land and starting a plan to adapt to the new climate change scenario. Top priority for parks implementation would be given to the edges of the Serra da Cantareira, Billings and Guarapiranga Reservoirs, and the headwaters of the Aricanduva River.

The process began by identifying strategic Linear Parks projects and water-producing areas; this was accomplished through the signing of an agreement with SABESP and through the creation of Green Areas Systems that would enable the consolidation of ecological corridors. Other areas for park implementation considered existing public vacant land and environmental significant structures such as water sources and valley floors, mainly concentrated on the north and south portions of the city.

The program was made financially feasible through private resources from TCAs used directly by entrepreneurs in park projects or works; through the Urban Development Fund (Fundurb) through the purchase of additional construction potential; through the Special Fund for the Environment and Sustainable Development (FEMA) through the auction of carbon credits; through the Municipal Treasury provided for in the budget; through cooperation with SABESP, which conducts the Clean Stream Program (Programa Córrego Limpo) in partnership with the municipality; and through company donations in exchange for the valuation of their surroundings (São Paulo, 2008).

The Clean Stream Program, a partnership between SABESP and the Municipality of São Paulo, started in 2007 and seeks to expand sewage collection and treatment in the municipality's river and stream basins. By 2012, there were 139 streams that had been depolluted throughout every region of the city. The depollution of waters is a prerequisite for appropriation of the linear parks, favoring the use along its banks.

São Paulo was characterized by heavy occupation of the floodplains during the industrialization of the city in the early 20th century, and many of its rivers and streams were channeled from this period forward. Even if they are not fully enclosed, at least the creation of troughs and the rectification of large parts of their beds are verified, and such practices were associated—until recently—with economic and urban development.

Different state regulatory agencies, such as the Department of Water and Sewerage of the State of São Paulo (Departamento de Águas e Esgotos do Estado de São Paulo - DAEE) and the Environmental Sanitation Technology Company (Companhia de Tecnologia de Saneamento Ambiental - CETESB), greatly contributed to this change in attitude toward the preservation and restoration of the waterways, allowing only for its partial channeling when strictly

necessary and strongly suggesting the "natural" use of the floodplains in order to enhance the population's perception and its access to this vital element of the urban landscape.

The linear park and its implementation processes

For the purposes of this article, we will consider a linear park to be a type of open space somehow associated with a water system, i.e., tracks adjacent to waterways and natural or artificial reservoirs. Its main goals include protecting or restoring the ecosystems along these bodies of water; connecting green areas and open spaces; controlling floods, and providing adequate open spaces for leisure, either in the entire area or just one part of it ³¹³.

A linear park is composed of the: Core Area: the Permanent Preservation Areas (APP); Buffer zone: transitional space between the Core Area and the Equipped Zone; Equipped Zone: areas created for social, entertainment and recreation purposes (LABHAB/SVMA, 2006).

Compliance with the APP legislation regarding conservation belts varies according to the degree of urban consolidation in the surrounding area, which creates conflicts between the segments involved.

Unlike the names provided in the Zoning Law, the SVMA (São Paulo, 2010) classifies municipal parks into: Traditional urban parks: parks with areas of biodiversity, leisure, culture; Linear parks: focus on sanitation, fighting floods, reurbanization and leisure; Natural parks: focus on protecting biodiversity.

The Urbanization of Slums, Clean Stream, and 100 Parks programs, all of which were implemented in an integrated and simultaneous manner as of 2008 – as well as the Watersheds Program – involve different municipal and state agencies, as already mentioned, and have resulted in the implementation of numerous linear parks, although not all of them are recognized as such ³¹⁴.

At the municipal level, there is some discrepancy in the classification of linear parks. Many are defined as such since their origin: this is the case of Linear Sapé (West Zone), Linear Aricanduva and Tiquatira (East Zone), Linear Fogo (North Zone), and Linear Parelheiros (South Zone). Others like Cantinho do Céu (South Zone) and Consciência Negra (East Zone) are not officially categorized as linear in the SVMA Guide (2014), but are recognized as such. On the other hand, the Praia São Paulo and Prainha (South Zone) parks, although located on the edge of the reservoir, are not considered linear.

We can also highlight that linear parks that originated from housing programs implemented by SEHAB were not even classified as parks until their transfer to the SVMA (Figure 1), though many of them had the necessary traits.

³¹³ We emphasize the frequent use of the term 'green areas' in urban and Brazilian environmental legislation in order to refer to urban public open spaces such as squares and parks. We understand that green areas could be a category contained in the open spaces in general. The 'green areas' term carries the connotation of vegetated and permeable spaces, while 'open space' considers all the 'non-built spaces', and conveys the broader idea of diversity of appropriations and forms of architectural and landscape treatment.

Other authors consider linear parks to be structures in which the determining factor is its length, regardless of any association with bodies of water; these include, for example, a park installed on an old railway, such as the High Line in New York, or Promenade Plantée in Paris; the Rose Kennedy Greenway in Boston; or the Parque Metropolitano de Manguinhos in Rio de Janeiro.

The Municipal Housing Plan (Plano Municipal de Habitação de São Paulo) created in the Serra-Kassab administrations, between 2006 and 2009, established long-term goals by the year 2024, and is considered a turning point for São Paulo's housing issues, as previously the sole function was to provide housing units with no broad urban intention. Enhancing the quality of technical projects (architecture, urbanism, engineering), the Plan started with a universal approach, with a key partnership between SEHAB and SVMA, and the decisive definition of sub-basins as the unit of intervention of the integrated program and project actions.

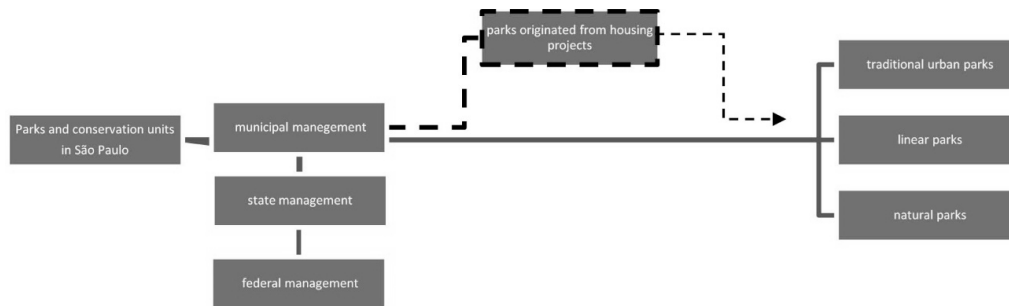

Figure 1. Diagram of parks and conservation units in the municipality of São Paulo, as found in the SVMA 2014 Guide.

Among all of the projects executed by the programs, one can verify the existence of linear parks along: waterways enclosed by avenues, with an emphasis on the roadways system; waterways in conjunction with large urbanistic interventions; reservoir banks.

For the purposes of this newly begun research project, we selected two emblematic projects as case studies due to their physical dimensions, complexity of biophysical support, number of residents, and precarious infrastructure in regards to social, cultural, economic and environmental aspects, which allowed for the development of differentiated proposals, both technically and in terms of landscape.

Vargem Grande design project

The project began in 2010 along with operations involving basic sanitation, energy and paving infrastructure. As an area permanently under the threat of occupations, the project turned as an integrated action that involved SEHAB and SVMA, still under construction. Included in the Watersheds Program due to its proximity to the Billings Reservoir, and within the limits of the Capivari-Monos Environmental Preservation Area (Área de Preservação Ambiental - APA) that, together with the APA Bororé-Colônia, it occupies a significant portion of protected land in the south end of the city. Another striking feature is its location on the Cratera de Colônia, a crater approximately 3.6 kilometers in diameter and that ranges in depth from 380 and 450 m, created by the impact of a falling meteor over 30 million years ago.

As for geomorphologic aspects, the crater has a relatively uneven topography surrounding the circular structure that stands out across hills and hillocks in the shape of a ring. The plain's dimensions vary from 820 m to 750 m tall (Figure 2).

It is characterized by the presence of some remnant springs and patches of natural drainage, and others altered by urbanization. The presence of significant fragments of the original vegetation can be seen in scattered parts of the region. Problems include flooding in lots and buildings, buildings with pathologies due to old infiltration, soil erosion, disruption of slopes, etc.

Located in the region of Colônia-Parelheiros, the place is home to 40,000 low-income residents, and it has been agreed upon, together with the Public Prosecutor's Office, that these residents will be allowed to remain there without increasing the settlement, in order to restore the environmental constitution of the watershed and facilitate the reconstitution of the local fauna and flora (Figures 3 to 6).

The loan for the project was made by The World Bank to SABESP, which is responsible for the management of reservoirs and other bodies of water in the State of São Paulo. This joint action between different agencies and spheres of government has allowed the development of large projects in São Paulo, with effective analyses of the complex environmental and social issues in a city where 3 million of its population live in precarious settlements.

Figure 5. Aerial View of Vargem Grande. (Source: Levisky Arquitetos Associated).

Figure 6. Aerial View of Vargem Grande. (Source: Levisky Arquitetos Associated).

The land regularization of Vargem Grande has not yet occurred since its purchase by the Union of Slums of Grajaú (União das Favelas do Grajaú - Unifag) in the early 1990s. This further complicates the area's urban evolution.

The intervention aimed to create urban and landscape projects in order to implement basic urban infrastructure networks (water supply and drainage, street lighting, sewage and road paving), plant trees along streets, create equipped and landscaped open spaces, and restore the vegetation in specific areas, especially those bordering the small streams that cross the region (Figure 7). With the street layout already pre-defined, the creation of interactive pedestrian pathways with environmental and cultural information regarding the site was proposed, with the idea of creating the Open Museum of the Cratera de Colônia, doing so simultaneously with the project's other multidisciplinary procedures.

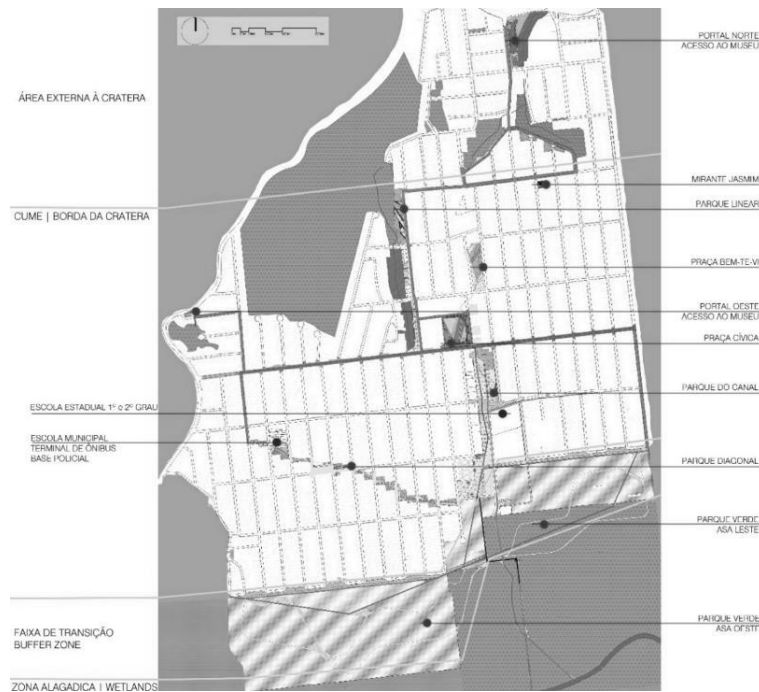

Figure 7. Open Spaces General Implementation Plan. (Source: Levisky Arquitetos Associated).

The existing roads were paved with interlocked concrete modular elements in four colors, thereby creating a directional transit system that is the same on both sidewalks and streets (Figure 8). Although the widening of some sidewalks was proposed, mainly along the roads with heavy pedestrian traffic and public transportation, the population was not receptive to that idea since it would hinder private vehicle parking. The residents' decision prevailed.

Figure 8. Treatment given to sidewalks and streets. (Source: Levisky Arquitetos Associated).

The open spaces were created after analyzing the opportunities the site provided. Vacant lots or partially occupied ones, which existed due to the presence of small intermittent streams, were connected, crossing minor roads and thus generating small and successive pocket parks within the block. In these areas were implemented playgrounds, street arborization and sitting places.

Figure 9. Canal Park General Plan. (Source: Levisky Arquitetos Associated).

The Civic Plaza was designed as a meeting place for residents; its chosen location was at a main street for walking and businesses, the Avenue of Palmeiras. It is an area crossed by two streams and endowed with many trees, native species of different sizes; a wooden high rise structure was designed to facilitate the natural drainage of the existing waters. With fitness equipment, playground and benches, and with the implementation of shrubby understory species, the area turned into the site's geographic and emotional core.

Four linear parks were able to be created. The Canal Park, of a more anthropogenic nature, is an effort to recover the area's most expressive body of water (Figures 9 to 11). Located beside the state school and already near the existing Atlantic Forest's area of conservation, it had its bed channeled, but left open, and its sides lined with concrete plates with openings for planting aquatic species. There are sports courts, skating rink, pergolas and benches for leisure, a playground, and more sophisticated plantings.

The other parks, established due to the need to ensure the integrity of the bodies of water located therein, have a more contemplative character with partially equipped transition areas (buffer-zones) and bush tracks, creating the connection between lots and the preserved area

itself. Regarding the preserved areas, a concept of ecological succession was adopted to ensure biodiversity and to attract fauna. Therefore, it was implemented bicycle paths and two observations decks to contemplate the scenic views (Figure 12).

Cantinho do Céu Design Project

Located on the shores of the Billings Reservoir which, together with the Guarapiranga Reservoir, holds a third of São Paulo's water supply, the Cantinho do Céu district is characterized by the extremely poor conditions of its urban infrastructure, not presenting a reasonable urban setting (Figure 13).

Part of the Watersheds Program, the Cantinho do Céu design project was developed with the participation of the Public Prosecutor's office, setting parameters that allowed keeping the majority of the population on-site, only relocating residents who were in areas of geotechnical risk. An urban project was then prepared that endows the area with a complete basic

infrastructure and a system of open spaces that meets the needs of the different segments of the population, contributing to urban drainage and protecting the area's bodies of water. New strategies were also considered that would harmonize the area's significant occupancy (more than 10,000 families) with the environmental legislation.

Figure 13. Cantinho do Céu General View. (Source: projotomehor.blogspot.com).

The intervention is the result of changes in the positions of government agencies at the municipal and state levels in an effort to face the current reality of occupation in the Watersheds regions as from the late 1990s. New indexes of vegetation and population density for social interest works were determined, fostering the development of urban and landscape projects with an emphasis on the creation of parks and other public open spaces. Integration with neighboring municipalities, such as Diadema and São Bernardo, led to the discussion of similar problems and a search for parameters for action, later carried out for the benefit of the communities involved.

The urban proposal is based on the concept of integrating new interventions with the pre-existing urban tissue, respecting the specificities of the settlement, working to improve accessibility and mobility conditions with ramps, stairs and new routes, and improving their connection to the existing roads and surroundings. Drainage solutions and the use of different paving materials according to road type were adopted, and resident removal occurred mainly in areas of proven risk, as well as in areas that prohibited access to sanitation and energy networks.

Concurrently with the implementation of basic urban infrastructure in the neighborhood, open public spaces were given great prominence, seeking to take advantage of the clear attributes of an exceptional landscape, one that is very different from the physical and spatial characteristics usually found in the city of São Paulo (Figure 14).

Despite the fragility of the environment and the large dimensions of the settlement, the proximity to such a large body of water makes Cantinho do Céu a naturally conducive environment for the creation of plazas, decks, pathways, and for generating local living and an enjoyment of nature, leading to socializing, recreation and leisure activities for different age groups with varied interests. The contrast between the rugged landscape, almost completely occupied with precarious, similar buildings, and the surroundings that have such a strong presence of vegetation and water, proves to be the trump card of this site, providing it with the resources for its own requalification.

Different sized spaces, equipped with street furniture, bleachers, stages, partially covered areas for holding meetings and discussions, open areas for small cultural fairs, fitness equipment, playgrounds, skating rinks, and courts provide areas for the different activities that are offered to the users for the development not only of everyday activities, but also for events that require larger areas (Figure 15).

The proposed Linear Park is about 7 km long (not yet implemented in its entirety) and borders the Billings Reservoir; on the other side it features an alignment of the walls and buildings that remained after the at-risk units had been removed. In the streets perpendicular to the track, subtle barriers preventing the entry of vehicles were implemented, allowing pedestrian access through small squares. The park is designed as a transitional region between the reservoir and the living area, and has its playful characteristics strengthened by the strong visual impact

of the chromatic panel applied on the buildings' gables and walls, which helped integrate the park with the built area.

Figure 14. Cantinho do Céu Leisure and Recreational Areas. (Source: Fany Galender).

Figure 15. Cantinho do Céu Leisure and Recreational Areas. (Source: Fany Galender).

The suppression of vegetation, native or not, in squatter settlements and slums, along with their extremely dense occupation and soil sealing is recurrent, and generally prevents significant afforestation. This is also the case for Cantinho do Céu. However, thanks to the possibility of gaining some ground on the edges of the already implemented urban project, it was possible the planting of native species and the conservation of the existing ones.

The local population contributed significantly by defining the program and the occupation of the area through workshops and the work of management councils, which helped to meet local demands and contributed to the success of the project and its implementation.

Conclusion

Linear parks have proven to be effective for conservation, contribute to the drainage system, provide leisure, living and recreational areas, bring rivers back into urban life, and reintegrate previously removed portions of the urban fabric.

Typically having a high urban, environmental and landscape impact, linear parks have been promoting significant changes in São Paulo's urban landscape, mainly in deprived areas that are in need of open spaces. The installation of recreational and leisure facilities and establishing them as sports areas is intended to strengthen the community aspect of many of these

interventions, and to assure the maintenance of these areas as open spaces, thus ensuring their stability and environmental restoration. In these interventions, there is also a requirement to reintroduce native Atlantic Forest species, as this is an effort to regenerate and restore forests and protect bodies of water, but to do so harmoniously with the urbanized context.

The new governmental management parameters brought about meaningful urban design projects and implementation of linear parks that have a significant role in the urban public open space system and cover a broad spectrum of functions.

Morphologic transformations of the public spaces in the surroundings of Nova Lima's churches

Marieta Cardoso Maciel, Maria Cristina Villefort Teixeira

Project Department, Architecture School, Federal University of Minas Gerais

E-mail: marietamaciel@gmail.com, mcrisvt@gmail.com

Abstract. *The present work aims at evaluating the transformations of central open public spaces in the city of Nova Lima originating from the Portuguese (1700-1884) and English (1884-1939) occupation periods focusing on morphology in different historical contexts until current times. The excessive number of improvised housings, gatherings and the reduced number of plazas and public parks necessary for public leisure were the motivation to this study, which also observes the environmental benefits within the urban perimeter of Nova Lima. This analysis will focus on open public and private spaces modifications in the central area of the municipality since the occupation started there and it also suffered Portuguese interventions and received English villages destined to mining. New landscapes appeared and triggered the search for reasons that could have contributed to the site's morphologic analysis. The places subject of investigation are located in the surroundings of Nosso Senhor do Bonfim, Nossa Senhora do Pilar and Nossa Senhora do Rosário churches including traffic lanes and existing public and private buildings. Also, occupied spaces (public and private), traffic lanes, citizens and existing natural remainings will be included in the analysis for belonging to the urban landscape. These are the elements which allow to evaluate the city's current configuration as well as its environmental quality, and that will certainly contribute to the improvement of the city's landscape and, especially, for the well-being of the population.*

Key Words: Urban morphology, open public spaces, landscape, environment quality.

Introduction

Urban forms are due to environmental changes of the place, in other words, the physical, biological and anthropogenic conditions, the latter as the main inducer of transformations. The cities and landscapes change when these conditions change and Nova Lima (Minas Gerais) is no exception to the rule. It expands increasing the conurbation process with Belo Horizonte.

The occurrence of major human concentrations and serious and constant biophysical environment degradation observed in contemporary times impose new conducts of public management and effective participation of city dwellers.

This problem is then addressed here because of its importance in the urban landscape and its morphology, as both are considered as systems and due to the complexity of its components, require specific analysis methods. Currently there is a need to introduce this issue in the city of Nova Lima, since improvised dwellings, settlements and the negligible amount of public open spaces damaged its environmental quality.

Objective

Thus, study aims to analyze the open public spaces (squares, parks, gardens and streets), surrounding the Nossa Senhora do Rosário, Nossa Senhora do Pilar and Nosso Senhor do Bonfim churches. These spaces must contribute to the urban environmental improvement with the benefits brought by permeability, urban landscape, existence of animal life and flora, microclimate maintenance, social gatherings and preservation of historic and symbolic memory.

Figure 1. Nossa Senhora do Rosário, Nossa Senhora do Pilar and Nosso Senhor do Bonfim churches.

History

The history of Nova Lima dates back to the late 17th century. The first name given to the site was Campos de Congonhas and marked the start of the spiritual life of the newborn village. With the small mining sites expansion, it became known as Congonhas Gold Mines (for the amount of gold found in the city), housing the working population.

The Nosso Senhor do Bonfim Church was practically built with the city. Its construction, in 1720, coincided with the start of mining activities, when Nova Lima was still Campos de Congonhas, and marked the beginning of the spiritual life of the rising town. Built of stone like the first houses, its altar was originally an oratory, where the image of Senhor do Bonfim was placed. Today there is a beautiful Baroque item transferred from the Nossa Senhora do Pilar church in one of its renovations. It is currently listed as a heritage building by the Nova Lima's Municipal Advisory Council of Historic Heritage and also marks the beginning of the area's occupation.

In 1748 the camp is elevated to the status of parish, and in 1836 the district is created and named Congonhas de Sabará, under the city of Sabará.

One example of the “mineiro” Baroque, the Nossa Senhora do Rosário Church was built atop one of the hills of Nova Lima, with its façade facing the sunrise. Built by slaves brought to work in mining, the works began in the first half of the 18th century and completed in about a hundred years. It is listed by Nova Lima Municipal Advisory Council of Historical and Artistic Heritage.

The Nossa Senhora do Pilar Church was built in the 18th century. It underwent some renovations, the largest of which in the early 20th century. This church stands out among the cultural and artistic values of the city for its examples of the great work of Aleijadinho. The entire set was listed by the National Historical and Artistic Heritage.

February 5, 1891 marks the city's emancipation, then called Villa Nova de Lima. Only in 1923 it was named Nova Lima and that remains today.

Methodology

The cities and their open and built areas once impacted by the dynamics of life are subject to constant morphological transformations, as stated by Alfonso Muñoz Cosme (sd): “Las ciudades y su arquitectura constituyen la memoria construida de una sociedad. En las calles y en los muros de las urbes se van acumulando los estratos del pasado, creando la obra colectiva más elocuente para expresar la historia y las transformaciones de la civilización. Pero la arquitectura

y los espacios urbanos son también el escenario del presente, que utilizamos para desarrollar nuestra vida y el espacio futuro que queremos crear, para disfrutarlo nosotros y legarlo a las generaciones venideras. Una ciudad que intente ser sólo una expresión del pasado dejará de ser una realidad urbana viva y se convertirá en un museo o en un parque temático. De esta forma una ciudad viva, una arquitectura viva, son las que reutilizan los elementos del pasado y a la vez construyen el presente e innovan el futuro. Toda ciudad y toda arquitectura han de transformarse para poder acoger las funciones actuales, para servir a la vida de hoy y así seguir siendo útil y conservarse adecuadamente.”

The urban morphology in Brazil started through studies with emphasis on economics, sociology and history. Later, the technical and formal aspects were added under Portuguese influence in the form of cities and their surroundings, and the buildings. The urban form is the result of various socioeconomic, biological, cultural and political processes occurring in time and space, which allow studies on diverse scales from buildings, neighborhoods, public parks and towns to the metropolitan area (Pereira Costa, 2004).

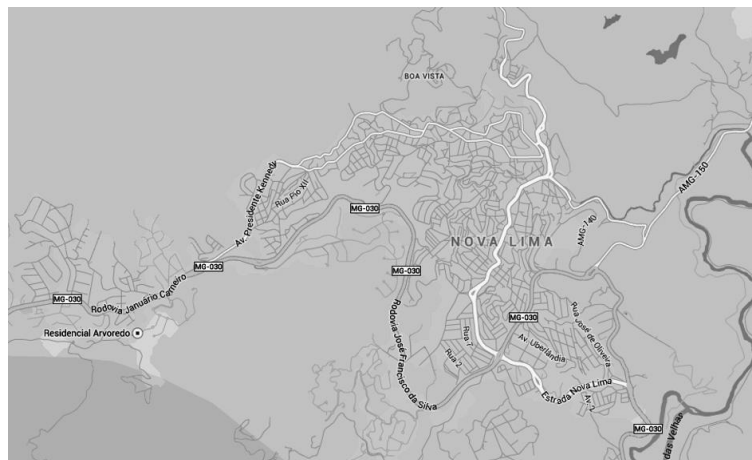

Figure 2. Map of Nova Lima.

In these new villages, "the streets were adapted to the more favorable topographical conditions, and tended to organize themselves as links between the points of greatest importance in the lives of these nuclei, with no intention of geometric ordering" (Reis Filho, 1968). According to Vasconcellos (1981), this is one of the features that distinguish the resulting occupations of mining activity falling on areas of improper topography and microclimate and sterile soil, motivated by the proximity of the mines - the case of Nova Lima.

Morphological analysis by Moudon (1997) is based on three principles: i) urban form is defined by three fundamental physical elements: buildings and their related open spaces, plots or lots, and streets; ii) urban form can be understood at different levels of resolution. Commonly, four are recognized, corresponding to the building/lot, the street/block, the city, and the region; iii) urban form can only be understood historically since the elements of which it is comprised undergo continuous transformation and replacement.

The public open spaces in the historic center of Nova Lima originate from the period of Portuguese (1700-1884) and later English (1884-1939) occupations.

The morphological changes occurring in the surrounding of the Churches of Nosso Senhor do Bonfim, Nossa Senhora do Pilar and Nossa Senhora do Rosário will be verified. Morphological analysis of the urban form will be based on the principles by Moudon (1997) of historical understanding, region scale and, as fundamental elements, buildings and their related open public spaces.

This means that open public spaces around these churches will be considered as the occupation began in the regions in which they are located and they also endured transformations, substitutions and interventions.

Analysis and results

Historical Understanding

Churches and religious orders played an important part in structuring Brazilian colonial towns, sometimes being the deployment of chapels in the origin of villages and towns, usually constituting the focus of polarizing urban growth.

In Brazilian culture, catholic churches are considered public spaces. “The correspondence between religious architecture and social organization in Minas is important for the understanding of this architecture, as well as of fundamental importance for the reconstruction of social development outlined by it.” (Vasconcellos, 1960)

Thus, the square appears as a central element in the urban area, located in the center of the village and being the operative element of the city plan. The layout of the streets and the urban structure were defined by it.

In the case of Nova Lima, the Legislative Palace, "Dr. Sebastião Dias Fabiano", functioned as a public jail until the emancipation of the municipality in 1891. From that date on it was divided into two parts: one for the City Council and one for the jail. In 1916 the City Council passed through its first major renovation. At the same time the municipal park was built besides church Nossa Senhora do Pilar, today named Piazza Bernardino de Lima. This park was then known as the Garden Square, housing major public events.

In 1948, with the first democratic elections held in the country, the City Council went to the headquarters of Villa Nova, where the Water Park is located today. In 1980, the City Council returned to its old facilities. In 1981, it underwent another renovation, something that disfigured its façade's characteristics.

In 1998, the City Council building was fully restored and enlarged with the support of the City Hall, being officially named Dr. Sebastian Fabiano Dias.

Understanding the scale: region

The area of the territorial unit of Nova Lima is 429.164 km². The 2010 Census assessed a population of 80,998 inhabitants and an estimated 2013 population of 87,391 inhabitants.

The city borders Sabará and Belo Horizonte up North; Itabirito down South; Raposos to the East; Brumadinho to the West; Rio Acima to the Southeast.

Figure 5. Map of Nova Lima's neighbour cities.

The city's population density is 188.73 inhabitants/km² and the Municipal Human Development Index (IDH) – longevity, education and income – calculated in 1991 was 0.523 and in 2010, 0.813.

The featured biome is Mata Atlântica and Cerrado. The Calçada Mountain, which frames the city, is one of the most beautiful postcards of the metropolitan region of Belo Horizonte, but it is threatened by the housing boom and mining activities.

Belo Horizonte has expanded towards Nova Lima (conurbation), forming several new occupation points, morphologically differentiated from its historic headquarters.

Figure 6. Conurbation of Belo Horizonte towards Nova Lima.

Figure 7. Belo Horizonte's occupation advance in Northwest Nova Lima.

Interestingly, the great fragmentation in the occupation of the studied subject city is due to the implementation of dozens of private real states along the major access roads (BR 040, MG 30, Inconfidentes Highway).

The topographical characteristics of the municipality also hindered greater cohesion between occupations and hence the historic core became isolated.

It should be remembered that the mining activity persists, leading the host city to host the mining workers, becoming essentially a "dormitory town".

Moreover, the increase in middle and high class residences in private real state properties substantially increased the demand for workers in the services sector. These events resulted in a disordered population growth in the host city with visible contrast in the urban setting and consequent socio-economic and cultural problems.

Understanding the form: buildings and their relationship to public spaces

In terms of public open spaces of the urban core of the city, specifically those of colonial origin, the focus of this study, some analysis must be made.

In the colonial period the public open spaces of Nova Lima were basically the piazzas and patios alongside the three churches built at that time.

Figure 13. Nossa Senhora do Rosário Church.

Among them, the Nossa Senhora do Pilar Church is the most imposing. It is located in the Bernardino de Lima Square, the center of the first area occupied in the municipality between 1700-1884. The Piazza Bernardino de Lima is the most important square of the city, if not the only one. It lies before the church's main façade and features the classic French style with its area spreading for almost twice the area occupied by the church.

The Bernardino de Lima Square is the most important square of the city. It lies before the church's main façade and features the classic French style with its area spreading for almost twice the area occupied by the church.

There are some commercial spots, services, residences, the Municipal Theatre, the City Hall and the City Council in the square surroundings. It is intensively used by inhabitants.

Figure 14. Piazza Bernardino de Lima.

Figure 15. Nossa Senhora do Pilar Church.

Figure 16. Nossa Senhora do Pilar Church and Bernardino de Lima Square.

The Nossa Senhor do Bonfim Church is the smallest between the three churches. The only existing open public space is a paved road that surrounds it, turning the church into its own roundabout. There is little vegetation and mostly in large pots within the space inside the railings that surround it. The space found on the left of the church also serves the State School Deniz Vale.

Figure 17. Nossô Senhor do Bonfim Church.

Figure 18. Nossa Senhor do Bonfim Church.

Day by day, cities are losing their public open spaces, their meeting places where people share their everyday life. The lack of investment in the creation and maintenance of public open spaces contributes thus to the decrease in public life. “Free spaces are the spaces of greater accessibility, greater capacity to receive diversity, plurality and the unexpected, features of a richer public sphere.” (Queiroga, 2011).

These changes take place because of the very dynamics of society when facing city growth, and the consequent increase in new buildings and vehicles, for which there is also growing demand for space. The decrease of open public space in the city or the change in their use is thus understandable.

Such characteristic allows us to assume that these open spaces were not designed with the goal of social agglomeration, in other words, they do not present the attributes of places intended for public interaction; they are places of transit or short stay, near commercial and services centers.

Thus, regardless of the physical or social changes of the currently existing public open spaces in Nova Lima, what can be said is that their occurrence is due more to the Portuguese influences, whereas the British had no significant interference to the local population in these terms. The development of the city as well as the emergence of these open spaces for social interaction occurred spontaneously.

Conclusion

Urban guidelines in mid 1750 advocated the existence of a large square in the camp, regular in form, where the City Council and Jail would be built and also the main church, usually devoted to the local patron saint, so that it could be raised to a village. The main square of Nova Lima was then implemented in the late 18th century, according to the formalization of Portuguese resolutions of the period.

With the end of alluvial gold, in the middle of the 18th century, the extractive activities went to the mines. Nova Lima went through changes in its urban conformation due to the development of new ways of occupying space and the first perimeter of the metropolitan area of Belo Horizonte was delimited in 1973, with the inclusion of the municipality. The conurbation with neighbour cities to the capital started.

It is believed that the process that occurred over time throughout the city of Nova Lima set the current conditions of these open public spaces, having acquired its own characteristics such as discontinuities, reduced dimensions and ambiances. Informally generated or not, these spaces followed the dynamics of biophysical and socio-cultural transformations of the city itself.

By analyzing the existing spaces around the churches, the conclusion is that there is no contribution of these spaces in urban environmental improvement because they are rare and impermeabilized, rendering biodiversity impossible to occur. However socialization and preservation of historic and symbolic memory still remains at Nossa Senhora do Pilar Church.

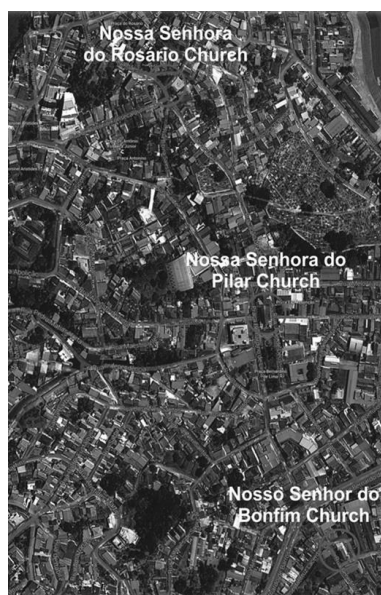

Figure 19. Map of the city's central agglomeration with the location of the three churches.

The decay of gold extraction began already in 1987, with today's prevalence of iron ore exploration, and the metropolitan expansion with the occupation of the edges of cities with private real estate properties and commercial and services areas.

It is believed that the process that occurred over time throughout the municipality of Nova Lima set the current conditions of these free spaces in the public realm, having acquired its own characteristics such as discontinuities, reduced dimensions and ambiances. Informally generated or not, these spaces followed the dynamics of biophysical and socio-cultural transformations of the city itself.

By analyzing open free spaces of public property (squares, parks, gardens and patios existing in the historical city perimeter the municipality of Nova Lima, it was found that there is no contribution of these spaces in urban environmental improvement because they are rare and

impermeabilized, rendering biodiversity impossible to occur. However socialization and preservation of historic and symbolic memory still remains at Church Nossa Senhora do Pilar.
