In the 90's starts the Favela-Bairro project in Rio. The main objective of it was to improve areas of favelas, with great focus in public spaces. It was a moment where "urbanizing" was the main word for these territories, and the issues of removals were not considered anymore. The project appeared in a time where there were still infrastructural issues to solve in favelas. It was implemented during the government of the mayor Marcelo Alencar, on the foreword of the definition of the city's masterplan in 1992.¹⁰⁵ The program is created in 1993 by the governor César Maia, being one of 6 different programs proposed by GEAP (Executive Group of Popular Settlements), and has as priority to do the minimum relocations, recover public areas without being too invasive, and to have interventions mainly in smaller favelas (with 2 to 10 thousand inhabitants). In 1994 the execution of the program is prepared, and the architectural offices that win the public competition have the autonomy to define the projects. In 1995 the International Development Bank injects more money in the project (through another program of popular settlements urbanization- PROAP), and Favela Bairro extends to around 60 favelas more. There was the idea of taking Favela Bairro to all the favelas of Rio, and it was already being taken as an opportunity to build dialogues between the inhabitants and the public authorities, however, with the new governor being elected, the program was stopped. (Burgos, 2006) The implementation of Favela Bairro is contemporary to the definition of Maré as a neighborhood, and José Moraes, the one proposing the change on the areas official denomination argued that with this new identification it could be possible for the residents of Maré to have more resources to fight for their fundamental civil rights. (Silva, 2006)

Nova Maré was built within the Favela Bairro process, in the 1996. It was the place for the resettlement of people that lived in risk prone areas in the city, together with residents from Maré that were removed from their stilt houses, in favela Roquete Pinto (Redes da Maré; Observatório de Favelas, 2012). It is interesting to analyze the project on the context of Favela Bairro, because the focus of the program was the construction of public services, urban infrastructure and revitalization of public spaces, and Nova Maré is an example of a housing project within an already structured territory.

¹⁰⁵ In the city's masterplan the favelas are first identified as Popular Neighborhoods (Bairros Populares), and there is an attempt to integrate these areas in the city. It considers the construction of new popular housing and the urbanization of favelas, with a definition of these territories that do not include any moral or cultural characteristics but only infrastructural and spatial.

It is a post-modernist project, south from parque Maré and east from Baixa do Sapateiro, built with concrete and brick with no finishing, differing aesthetically from the other public housing projects that exist in Maré, that had a more modernist approach. It proposes an organization of the houses in groups, with common public areas organizing the space. The houses are structurally made so that they won't support a vertical increase, and the roofs are pitched. The circulation within the area is done so that it connects the small public spaces, with the main streets bordering the area.

Today, Nova Maré is the poorest area of all Maré and also the one with greater conflicts. It is told among the residents that a big part of the drug dealers in Maré do live in this area, and that because of that the door numbers of the houses were removed, so that it would be more difficult to identify the houses. It is also the only favela of Maré that does not have a mail service door to door, also in relation with that.

The small open spaces proposed by the project are being occupied by new houses, and the houses are being transformed in all the favela. Some public amenities are sometimes removed, as the population does not feel they want or need it. It is probably the area of Maré that today is passing through a faster transformation and adaptation process. It is common sense in Maré that Nova Maré was an unsuccessful project and its residents are not satisfied with it. Its morphological definitions and restrictions limited the adaptation capacity of the area, and the decisions within the project do not supply the social and individual needs of its inhabitants. This is a paradigmatic case within Maré where the regularity and rationality led to the dilapidation of the area because it didn't consider the adaptative processes of its residents, and tried to fix a pre-concept of housing and use of space (the fact that the houses have apparent bricks, looking unfinished and there is no allowance to finish them with paintings, for example, brings back the stigma of the favela as the place of informality and permanently unfinished).

Salsa e Merengue is the newest area of Maré. It was built in 2000, and is composed of small houses. It was built for the relocation of families from other favelas of Rio that suffered from floods and landslides. Its original name, Novo Pinheiro, makes reference to Vila do Pinheiro, the community aside, but because the houses were painted in a very colorful way, it started to be called as the Salsa and Merengue community, making reference to a soap opera that was famous in that period. (Redes da Maré; Observatório de Favelas, 2012).

Public spaces

In the 7 World Urban Forum, the Future of Places initiative hold a conference series which included the event Public Spaces in Favelas and Slums. In this event, key stakeholders agreed on the “the potential of participatory urban planning, utilizing public space as an instrument to promote equality and poverty reduction; specifically regarding marginalized communities.” as well as on the need to understand “the importance of understanding the dignity behind public space and its essential role in favelas and slums.” (Future Of Places, 2014)

In Maré, as well as in other favelas, the public space is not necessarily regularly defined, but extends to the public areas that exist within. The streets are often an extension of the houses, and become multifunctional areas. In Maré for example, Rua Teixeira Ribeiro in Parque Maré is a clear example of how a street can become an open air mall, or a street week market, with almost all of its sidewalks occupied by the commercial activities that happen along the way. There are also bars and small food services that extend to the sidewalks, and the whole street becomes a dynamic public space. There are many examples of this situation in Maré, with several food markets in different favelas, and with a very usual usage of alleys and smaller streets as an extent of the house.

There are also more formal public spaces, small squares or sport areas like Vila Olímpica and football fields. In the case of Vila Olímpica, being a gated areas with access control and with an extremely formal process of admission of people in their activities (with waiting lists, dependency on the availability of teachers, etc), it is a space barely used, and even though it occupies a huge amount of land and has several sports amenities, it is most of the times with

very few people using it. This severe control of public spaces also happens in other formal areas in Maré. Some football fields have their access controlled by the parallel activities of drug dealing, that charges the usage of some areas and the moments for them to be used. Even in some areas where this control is not done directly, there is an indirect influence of the parallel power over the usage of space.

The urbanization and improvement of public and common spaces, and also its morphological definition is fundamental for the structuring and development of the areas, as long as it reflects the flexible use of spaces and its capacity to be adapted to different functions. Once the priority of occupations in Maré is related with housing provisions, formal public spaces are usually neglected in the process, for not being considered a priority. However, the way that free areas are taken are a clear message that there is the need for qualified common amenities and infrastructures. Streets, sidewalks, or squares may have the potential to connect areas within Maré and concentrate or disperse local dynamics, if understood from the perspective of the local needs.

“The private realm often extends into the public sphere due to the proximity between homes and the narrowness of the roads and pathways. This proximity creates multiple social spaces, allowing conversations to take place from window to window, doorstep to doorstep, balcony to balcony. Rooftop gatherings, too, are a popular affair in a private extension of collective participation. (...)”

While the favelas inherently belong to residents, drug traffickers, militias and police forces have overarching effects over the public’s freedom to enjoy a space. Thus, the notion of scary space is introduced as one where crime and the fear it instills dominates the perceptions associated with a place and affects the ways it can be used.” (Dixon, 2014).

When in the 20th of April the Avenida Brasil was closed in the area that passes in Maré, for the execution of constructions works, the population used the area for recreational purposes. (GLOBO, 2014) It was an evidence that there is the need for quality public spaces, and also that the challenge of adapting urban areas for other purposes is something that the residents are used to do. It was a lesson given by the inhabitants of that area, of their intense desire of having public spaces and the right to a city that morphologically supports their urban needs. And public spaces may have the capacity of changing cities but more than that, changing them within a collective thinking.

The right to the city is far more than the individual liberty to access urban resources: it is a right to change ourselves by changing the city. It is, moreover, a common rather than an individual right since this transformation inevitably depends upon the exercise of a collective power to reshape the processes of urbanization. The freedom to make and remake our cities and ourselves is, I want to argue, one of the most precious yet most neglected of our human rights. (Harvey, 2008)

Ideas for re-classification, re-understanding and re-thinking planning positionings towards the favela

Idea 1: if maré is a slum, then it is a slum that is unslumming since ever

Slum and Unslumming – lessons from Jane Jacobs

Podem me prender
Podem me bater
Podem até deixar-me sem comer
Mas eu não mudo de opinião
Aqui do morro eu não saio não... ¹⁰⁶

¹⁰⁶ They can arrest me / They can beat me / They can even leave me without eating / But I don't change my mind / From the hill I don't move”. *Opinião*, by Zé Kéti.

Leveling this knowledge up to urban form, and focusing on the specific case of the favela, one will understand how the categorizations that favelas have had are resulting from specific contexts of relative comparison, and that actions within the favela do take place upon its regional classification. From Jane Jacobs we find an interesting perspective over what she calls “slumming and unslumming”. As we read through it, it states clear that, according to the history of favelas and specifically, of Maré, that when we approach these territories we shall definitely understand them as something else rather than a slum – or the regional classification she presents – , but take from her perspective the potential of understanding how situations, networks, interactions and, in the end, attachments may be the key for unslumming processes.

According to Jacobs, unplanned slums result from the abandonment of urban areas that are not welcome anymore to wealthy, usually white people. These inhabitants move somewhere else within the city, to more “valuable” places and leave their old neighborhoods deserted. This is the starting point for the formation of a slum: immigrants and usually black people buy these houses and settle in these areas. Usually there is a very fast population growth in these areas, and it gets overcrowded, and as Jacobs says, usually people are always looking for a chance to move from these places somewhere else in the city – a safer and more desirable place. Slums can also be planned, when the public authorities decide to build public houses for people relocated from other areas of the city.

From this understanding, one may identify the regional categorization that is given to a slum, and if Maré was build – as we will see during this study – from nothing, there are processes within the construction of this place that remind us of the traditional slum creation that Jacobs speaks about. However, as we will see later, if it is to consider that Maré was a slum, once upon a time, now the regional understanding must change.

“The foundation for unslumming is a slum lively enough to be able to enjoy city public life and sidewalk safety. The worst foundation is the dull kind of place that makes slums, instead of unmaking them.

Why slum dwellers should stay in a slum by choice, after it is no longer economically necessary, has to do with the most personal content of their lives, in realms which planners and city designers can never directly reach and manipulate – nor should want to manipulate. (...)

Indirectly, however, the wish to stay is obviously influenced by physical factors in the neighborhood.” (Jacobs, 1961. p.279)

From the lessons learned of American slums through the perspective of Jacobs, and thinking about Maré as a favela, the proposal is to find a relationship between unslumming foundation processes as proposed and the reality that is today being lived in Maré. The stories within the history of Maré tell us, similarly to many other stories of many other favelas, about places of struggle, of strong and persistent processes and actions from the populations in order to stay in those areas and not to be removed from there. In the case of Maré we may see from one side, the conditions that turned that area into a possible area for the poor ones to settle – a place close to job opportunities, in a mangrove area, not desired by the middle and upper classes, where people could built their houses free of charge – , so one may say that the population was directed to this area, but on the other hand, we see a constant strength to stay in those areas and to improve the houses and also the urban infrastructure.

“As the family grows, or additional resources become available, the shacks are improved through “puxadinhos” and the cheap materials are substituted by better ones in a continuing adaptation process.” (Vaz & Jacques, 2004)

So, if in one hand we have conditions that are similar to the foundation of a slum – occupation of undesirable land – on the other hand it is clear that the population carries within their territorial story lessons of an unslumming process that is happening since the very beginning of occupying Maré – with the army demolishing the houses and people re-building them on the 40's, the construction of their basic infrastructure and improvements of houses, building with more permanent materials, or growing the houses as the inhabitants economical conditions improve.

Considering this, one may say that, if we want to talk about favelas as being a slum, then we shall consider them as a slum in a continuous process of unslumming, and both concepts are then born together. Or one may consider, from a planning perspective, these evidences as open messages from the local population of a strong dynamic of urban improvement happening within the favela. It may be the role of planners and politicians to carry about supporting urban improvements, the achievements of greater urban quality and, as Perlman says, “sidewalk safety”, but it is not their role to define or try to manage the reasons why people choose to stay. But as we see historically, it seems easier for agents of formal transformation to create potentially “planned slums” than to support unslumming processes that are in action.

Idea 2: favelas are not informal settlements: they are full of form! Proposing an alternative classification – towards the spaces of adaptation.

Proposal for a contemporary updating of understanding urban dynamics and morphologies of the favelas.

Regular vs Irregular

Considering the specific dynamics of urban development within Maré, it is not possible to keep on talking about informality when considering these territories, and it is clear that these spaces are not urban ghettos or shantytowns as we know them from other international examples. Favelas, and specifically Maré, exist and develop within their very specific continuing struggles, resulting from a constant battle from people to find and build their place and identity in the city. Favelas have logics that are developed from their own necessities and challenges, and what is usually called as being informal is nothing more than the simple misunderstanding or no-understanding of another perspective of urban development.

As it was seen, the irregular territories are usually related with the local logics and the self building of the place. Irregularity comes from the sum and bridging of many individual efforts within a common ground. It represents the continuous struggle to fix a space within a territory, and its morphological definition stamps with great accuracy the flexibility of these actions and the logics that come from human needs and social life, much more than from technical conceptualizations, or Cartesian understandings of space. It is the planning upon the needing, in a constant adaptation to everyday challenges, threats and conquests.

On the other hand, the regular communities mainly results from planned initiatives of development. Either locally organized or resulting from state initiatives, these spaces have in their orthogonal and clear space definition the confirmation of a planning process that was based first on land, then on human life. In some cases, the regularity and ruling was so and inflexible that ended in prejudicing the improvement of some spaces (i.e, Nova Holanda). Regular territories within Maré represent the planning logics of each specific time, the planning paradigms and the political moments of the city.

Favelization or Adaptation?

If the more irregular communities are built on a bottom-up approach – people develop and build the territories and later on, the official services and infrastructures are provided - , the more regular ones follow an approach that is from above – the places are built and then people adapt them to their own needs. Somehow, when these events happen in poor areas, they are named as a “favelization” processes, for both cases: when people occupy land, and when popular housing or urban infrastructure is built and then transformed by the population. Considering that “favelization” is a very abstract concept, we rather talk about adaptation processes.

Both regular and irregular places, no matter how they are built, attest the societal development, political interests and economic strategies of the city. These realities are the real cards to play the urban planning games, since they are the greatest determination of where do

people live, how do people understand the relation between housing and work, where is social inequity based on economic values and accesses, which city is wanted and for whom. Then planning must be seen from a broader perspective – it is not the simple organization of space, but must be the understanding of the inner forces of urban development. Planning, in Maré, was done from the first moment, when Mrs. Orozina planned to stay on Timbau hill, when other people planned to build their houses to be close to the (planned) new industrial city. Planning was when the military turn houses down and controlled the occupations, when fundação Leão XIII had their roles defined, when the governor decided to put people in temporary houses, planning a more civilized city. And finally, in a classical perspective, planning was when Mr. Margarino Torres organized and controlled the development of two communities, when the municipality built low income modern and post modern housing units, when Projeto Rio relocated in new buildings people living in stilt houses.

What we may find different from Maré and other favelas in Rio from the rest of the city (or the “favelization” processes) is their continuous capacity of adaptation to reality and needs. In the formally planned city, the organization of space illustrates future investments and strongly organize the way people live in the city. In the case of Maré it can be seen that space is adapted to the population needs, to the topographical and geographical conditions, and in the end, to the logics of the other city. It lives a constant adaptation process and when space lacks flexibility it will be confronted by the local needs.

It seems necessary to propose a new classification for these territories, replacing the des-informed and obsolete informal vs formal dichotomy: favelas are *adaptive* and *adapted* settlements, that can be morphologically regular or irregular – they are spaces of adaptation and reciprocity¹⁰⁷. This new classification may help society, politicians, and also planners, to understand the direct relation among these territories and the local realities, and state clear that there is no such thing of excluded places, living in constant informality, and within some sort of local autism.

Planners shall understand that these are areas of constant change and that flexibility is fundamental, they shall shift paradigms when including these territories in their plans and researches and classify and work upon them understanding their specific logics and histories, their own challenges and never-ending stories.

Idea 3: breaking dogmas supported by the morphological understandings

On her great analysis of researches done upon the favela theme, Valladares (Valladares, 2005) presents us with a series of dogmas that appear frequently in the works done. The proposal is to try to understand, from the morphological story of Maré (considering its multiple inner stories and the greater story of the city as a whole) to reflect upon those dogmas.

Dogma 1: Favela as a completely specific and singular space.

Favela has a very particular way of occupying urban land, without urban infrastructure and in a irregular way. It has a very specific aesthetics of housing, and according to official perspectives, it is a place of exception, where illegality and occupation against the norms established are the main rule. Therefore, favelas shall have exceptional politics considering their exceptional and singular contexts.

As it was presented, favelas may have completely different realities within it. They are a response to established rules that regulate urban space, processes of urban market that exclude the poor ones from accessing housing in the formal and legal cit, só they don't appear from

¹⁰⁷ In its research about space organization in favelas, John Dawsey supports the idea of a space of discipline (resultant from processes of urbanization) in contrast to spaces of reciprocity, organized by residents of favelas in their struggle to survive to processes of marginalization. He supports that both organizational forms are resultant from contrasting cultural processes. (Dawsey, 1989)

exception but from the answer to the established rules that can't include all different urban needs and priorities. There are also different cases of favelas built by the rule directly, such as the case of all the popular housing built in Maré, or the housing projects (temporary or permanent) built back on the 60's. They are just examples of how favelas are not singular, independent or specific, but an urban fact that results, as all other urban facts, from its specific political, economical and social context.

Dogma 2: The favela is territorial and socially the urban place of the poor.

This dogma would mean the favela residents build a city within the city, the illegal territory inside the legal one, in a very well defined limited zone, with their own economy, inner laws and specific codes. It is the theory of the broken city, of urban exclusion.

What we know is that the favela lives economically and socially completely integrated in the city and that its territory results from the evolution of the whole city. Maré, for instance, has its territorial history completely dependent and connected with the urban transformations that were happening around and the economic opportunities that opened in the area, mainly related with creation of jobs in construction and industries. There is not the case of urban exclusion, but of urban differences within the same dynamics. If the favela is there it is because the city wanted and also needed it to be there in order to be the city it is today. Even inside Maré, there are different economic realities and valued places, there are different social relations and political consequences. And if the analysis would extend to the rest of the city, it is today very clear, with the processes of gentrification happening, that the favela can't anymore be considered as the place of the urban poor. Also, the favelas of Rio are much more an issue of inequality rather than a question of poverty.

Dogma 3: Favela as an unit. All favelas are reduced as a single category.

Favela is spoken in singular and lacks the interest about their inner diversities. There is the tendency of speaking about the favela as a ideal paradigm, with great number of studies and analyses focusing on the differences among favela and the rest of the city.

There are not only differences between favelas, but also inside a single favela in its different areas. Even morphologically speaking, there are favelas structured more organically, in hills, others located in flat areas, others that were slightly conquering their spaces and irregularly forming. There are favelas with different urban densities, and located in completely different places of the city. They have their own contexts and structures, and even socially, they have specific organizations and mobilizations among their life as urban areas. It is fundamental to take a deeper look to the differences of these areas instead of building generalizations and unifying wrong conceptualizations, that can only under estimate and misunderstood the common knowledge and weak the potential capacity of acting and work for the improvement of these areas.

Idea 4: rio and the mega events: this is not an excepcional moment in the city

In the past the city of Rio hosted several mega events. Specifically on the 20's and on the 40's, these events where strategic arguments for the public authorities to take action upon urban development and it had direct impacts in the life of the urban poor, with great number of removals in favelas of the city. When looking to the events with more attention, one may understand that the execution of those urban initiatives were planned and debated long before the events started.

As Soares Gonçalves presents, "he organization of mega events in the first decades of the XX century had a strong pedagogic role to build a new society and eliminate the points of diversity. The building of a pretentious agreement about the future of the nation was expressed also in the way to act in urban space. The time urgency to prepare the city allowed diverse

negotiations, with improper use of public budgeting and giving benefits to certain economic groups, namely the ones connected with civil construction and real estate market. Even the mayor was pointed of getting undue benefits in the demolition of Morro do Castelo”. (Gonçalves, 2013)

Some of the specific episodes help in understanding how the mega events had an important role in sustaining and acting as an argument for urban actions that have within them other interests and consequences. Today, Maré is facing this new urban context, with the same old stories. There is no perceived risk of any intention from the government to evict the favela, or to take the territory for other investments, but it is also true that new dynamics are happening, and that in total, around 30000 people were evicted in the context of the preparation of the world cup and the Olympics.

This year the army occupied Maré, with the main objective to take the organized crime out of there and, as it is usually said, to re-take the territory to the public power. It is promised since last year that Maré will have an UPP, a pacifying police that has been taken as a model and implemented in many different favelas of Rio. At the same time, it is true that the strategy to occupy Maré now has a direct relationship with the upcoming world cup event, and the territorial and geographical context of Maré – it is located on the middle way, from the international airport of Rio to the city center. The decision to position the army in Maré now has, once again, its origins in a perspective of control of this territory, and the understanding of it as something that need to be supervised and managed as a dangerous and informal place. Once again, the territory has its challenges and opportunities directly related and dependent on the history of the city, but once again being positioned as the different city, where the actions taken in order to get ready for the mega events differ from the processes in the other, formal, city.

The UPP process has brought in some territories a classical gentrification process. It is also a repeated story, that happens at least since the early XX th century in Rio, with the government of Pereira Passos and his great urban transformations. With UPP favelas, and mainly the ones located in strategic urban areas, become places of interest from the real estate market. Also with regularization, people that were using basic infrastructure self-built, without supervision, now need to pay for these services, and in some cases this is a strong reason for leaving the places and moving far away, into suburban areas. This gentrification events, with rise of house values and expenses with services are a real threat to places like Maré. On the other hand, the occupation of the territory and the certainty of a UPP coming to Maré opens up the perspective of new opportunities, and the population is organizing themselves to build up dialogues with the municipal and the state government.

On the 6th of April, the mayor announced that the program Bairro Maravilha, that was being implemented in areas of the city that lack interventions from the public government, will be implemented in Maré. The objective is to improve urban infrastructure, but the mayor had also announced a great investment in education for the area – the building of new 7 schools, 5 kind gardens, and an educational campus. The mayor has also confirmed that the public government is taking action over Maré for a long time, and that the biggest issue to face was actually the armed drug dealers.¹⁰⁸

It is clearly a positive perspective over the urban needs of the territory of Maré, but once again, it is made upon a principle that it is a territory to be controlled and that things could not be done without the presence of the army. The majority of the 30 000 people evicted in the context of the mega events are being relocated far away in the city (62% of Minha Casa Minha Vida projects, a federal program of low income housing to where some people that are being evicted from favelas are being relocated, are placed in Santa Cruz, in the west part of the city, extremely far away from the city center and the richest neighborhoods in the south zone), and these dynamics immediately remotes us to the policies overtaken back in the 40's and again in

¹⁰⁸ “Prefeitura levará obras do Bairro Maravilha para a Maré” in <http://oglobo.globo.com/rio/prefeitura-levara-obras-do-bairro-maravilha-para-mare-12111391#ixzz31SClzpUS>

the 60's.

Conclusion

The form of the informality is built through a series of relations, conflicts, challenges and achievements that build historical relationships between public authorities and the population. The urban strategies are tactics determined mainly to accomplish clear urban objectives, and the urban development of favelas – its origins and continuous evolutions – result from these relations. Economic strategies, political positioning, and social contexts define the final layout of urban complexities and definitions. It is not different in urban morphology. As we saw from Maré, the form of this territory is always built among these complex dialogues, revealing stories of struggle and resistance, or top-down initiatives of urban permanence, but it is always a plan that exists behind the plan. The idea here is to bring up in the air the notion that planning has much more to do with this level of decision rather than with the morphological conceptualizations of space. Therefore, favelas as places need to be considered and read from its own background and from how these areas are integrated in the whole sequence of local and global events. From the learning of Maré, one may understand for example how in the 60's the american financial support given governmental projects ended up in supporting a whole series of removals and urban traumas. At the same time, the fact that Dona Orozina herself, decided in staying in Timbau without allowance had a strong impact on the history and on the definition of that place. And today, the mega events, the processes of gentrification, and the pacification processes are also building new urban definitions, interpretations and also, new morphologies. The role of the planner or the architect in this game is, one may say, indifferent for the whole story. But then, what can we, as planners, as architects, and as social actors, do for the achievement of a more fair, equal and morphologically understandable city?

The question should be on what do we want for our cities, and how do we see our cities. The proposal of this research is to suggest that first of all we shall understand how we identify the space of favelas, and what could be, in the end, their common essence. And, to what concerns issues of urban morphology and layout, its common essence is a matter of process, and not a matter of product. There is not a single favela equal to another, there is no definition of form within these places, but there is a common process of *adaptation* that follows all paradigms. And understanding this first, may be a good start.

Acknowledgments

I would like to express my appreciation for the support given on this research from Mrs. Katarina Nitsch and Henrietta Palmer from the Royal Institute of Art and also from Mr. Rafael Soares Gonçalves, Mário Brum and Mauro Amoroso. This exploratory thinking may be continued.

Fernando Távora and the portuguese urban space design

Carolina Ferreira

Department of architecture, Faculty of Sciences and Technology,

University of Coimbra.

E-mail: carolina.darq@gmail.com.

Abstract. *Our urban context is considered in new and complex ways, in which territory is no longer a mere network or mesh, but an interaction of different plans and systems of urban life relationships. A territory constituted by several layers that either continue or split from urban collective memory, we are challenged to grasp the urban question by studying the processes that occur while a project is created. This paper aims to reflect on idea-based construction processes seeking to intervene in the urban space by looking at the theoretical and practical career of Fernando Távora (1923-2005) - a Portuguese architect who has influenced the teaching and practice of this subject in Portugal from the 1960s to the present time. It will begin from the General Plans and Urban Arrangements carried out by Távora and his team, during the second half of the 20th century in several Portuguese cities, namely Montemor-o-Velho (1951-59), Aveiro (1962-63), Barredo in Oporto (1969-76), Guimarães (1979-86) and Coimbra (1989-1992). Fernando Távora's work supports a methodological position of the utmost importance to our time: to intervene locally, according to global strategies, establishing as many relations and continuities as possible; in other words, to act surgically, promoting an effect of surrounding contamination.*

Key Words: methodology, urban Intervention, urban design, Fernando Távora, Portuguese space design.

Fernando Távora and the portuguese urban space design

The Portuguese Urban Space Project is, from the origin of nationality, a form of organization of human relations in the territory, building spaces of various kinds: political, social, economic, affective, among others. The definition of its forms has been throughout the ages, and for specific circumstances and needs, one of the objectives of the discipline of architecture.

With the project, the architect was able to idealize, imagine and design varied urban realities and communicate them. Idealistic, utopian, realistic, conceptual - cities experimented different ways of being, always needing to reinvent itself and ensure its continuity. Therefore, the act of designing had and will have an important analytical and purposeful role in helping the thinking and influencing the future of urban culture.

The Portuguese urban territory has followed different directions and forms. The use of urban design throughout the ages served various purposes such as defending and controlling, the affirmation of political, spiritual and economic powers, expanding the territory to colonize, unite or separate, strengthening or weakening, innovating, to modernizing and surprising, correcting, to aggrandize and / or improving the existing one. They all guided methodological approaches to suit each context, without ever having been able to define a 'methodology', which would serve as a disciplinary model. Perhaps for this reason, Fernando Távora understands that "in architecture, the opposite can also be true."¹⁰⁹

In fact, the design process is nonlinear and permeates each step to another, adjusting to the conditions and necessities of each time. The configuration of the phases and the choice of tools

¹⁰⁹ This is an autobiographical sentence from Fernando Távora which was referred to as "personal communication" in a note by Marius Kruger (2005:128, 147). The sentence was associated with a statement of Fernando Pessoa, in a text from 1927, related to classical and romantic poets (Person, 1993: 157), by Jorge Figueira (2012: 44) and Silvio Alves, who is devoted to the study of relations between architecture and literature from the work of Fernando Pessoa and Fernando Távora.

are organized to suit a problem. The architecture deals, thus, with dynamic processes and therefore has to reconcile different perspectives, while working with the very objective condition of the object and the subject's own subjective condition (Koselleck, 2009).

The understanding of architecture has changed over time and ought to continue its transformation, developed in the light of the main planning and methodologies reflected in future forms of social organization. The methodological indefiniteness is also a factor of the design of today's disciplinary inconsistency factor, placing the subject in a fragile position and with ill-defined borders in the urban context. These uncertainties raise some questions:

How should the discipline of architecture position itself in front of the urban reality? How should the architect intervene on urban problems? Will the creation of new methods of spatial analysis be necessary to argue more practical forms and their options, and thus be able to act in a multidisciplinary overview of more active and participatory way? Which is, after all, the disciplinary specificity that distinguishes architecture from other forms of intervention in the city? While architects, how do we contribute to the Portuguese Urban Space Project?

To think the architectural project to intervene in the future of urban space is now a necessity. According to the idea of Aureli (2013: 14, 15), the inability of the architect to shape the city, has been presented as a *fait accompli*. The growing ineffectiveness of architecture in providing answers to the social and political problems. This idea has been underestimating the power of architecture to influence our reality and the urban condition.

In this sense, it is the purpose of this writing, to reflect on the project of Portuguese urban space from some work carried out by the office of Fernando Távora in the cities of Montemor-o-Velho, Aveiro, Oporto, Braga and Coimbra. During the second half of the last century, Fernando Távora developed some studies and urban proposals that depict important moments of reflection and construction of an approach to urban intervention. The Portuguese urban narrative, learned from these cases, aims to raise awareness of critical issues and problematizing the current urban reality, subjecting them to a reading based on the reconstruction of the thought processes behind the forms, allowing us to understand the construction and the importance of a methodology disciplinary project for the Portuguese Urban Area.

This approach integrates the current debate on the contemporary city. The disciplinary position of architectural practice in the (re) urban design, identifies instruments and tools that can assist to research, to reflection and to question reality - a phase of analysis - for the formal implementation of ideas - synthesis.

From analysis to synthesis

"Being collaborative, works of Architecture and Urbanism will be summaries, plastic translations in those space organized by whom and for whom they perform. (...) It is largely in the hands of Architecture and Urbanism to organise the environment in where Man lives, the buildings where he dwells or works, cities, regions or countries where he is integrated. "(Távora, 1952:155) The preliminary plan of Montemor-o-Velho, 1959, still inserted in urban policies from Duarte Pacheco, was a turning point and confrontation with the complexity of urban problems. It was also the moment he entered as a teacher for school Fine Arts in Oporto. Thus, arising the opportunity to approach the teaching and practice of architecture, bringing the themes and works which we developed in his office for the school.

In 1951, Távora began to study the town of Montemor-o-Velho, which would last eight years, up to the formulation of preliminary plan's proposal. The document was written and composed by drawings, in addition to photographic records of the city at the time. In a descriptive memory all research and analysis was collected to support its proposal for territorial organization of the village. Távora analysed the current state, contextualizing Montemor-o-Velho in Portugal and characterized the natural conditions where it was implanted. He also prepared a historical evolution of human occupation and a demographic study.

In this process, Távora sought the understanding of the territory for the design, using it as a tool of analysis. He developed means of representation that reflect aspects of the organization of the territory of Montemor-o-Velho. Plans of situation were drew up, first in the country, then in the district, followed by the county until defining and limiting the area of study and intervention, by defining the field of action where urban life unfolds. Additionally, Távora produced plants topography - to show the direction of Montemor deployment in its relationship with the hill, river and canal. He Drew up a plan of construction of the building in relation to the castle district, other of the road system of the city, another of buildings representative of civic commercial, health, religious and sports centrality, types and condition of housing, etc.

Overall, this review process has looked at political, social, economic, geographical, cultural and spiritual organization way to, in the end, understand the city as an organism, realizing the way it works and feel. This methodology reveals an enormous sensitivity to the experience of place and people's experiences, always seeking strategies of continuity with the existing, avoiding fracture. The rupture understood as the loss and / or destruction of the references that connect people among them in space.

Based on these principles, the plan connected the possibilities of analysis from various disciplines to characterize the identity of the place. It culminates in a synthesis phase responsible for the formalization and realization of a proposal based on the economic structure of the village, strengthening the agricultural nature of the site. He proposes plots / lots for farming, strengthens the concentration of housing area in East slope of the hill, around the castle wall, and defines in the lower zone a track for the development of more public nature programs.

"Factors as varied as scientific thought or religion, economics or sensitivity, politics or philosophy therefore constitute facts of the organization of space, condition of the forms that organize, in addition to pre-existing forms (...). This makes sometimes difficult to discern from the importance of one on the other (...). The most understandable to the viewer so that they will better portray, that which he most identifies with, the one he knows by connaturally (...)" (Távora 1962: 22)

The act of designing is understood as an act of investigating in order to learn, operate and transform the territory. Involves a maturation process to clarify intentions and pin down strategies of organizing space.

Figure 3. Preliminary plan of Montemor-o-Velho, April 1959.

Figure 4. Aveiro's Centre Renovations, Tower, Plan, Sketches, 1962.

Rupture or continuity? The new medieval.

Two years after the Montemor-o-Velho plan in 1961, Távora was called by the Municipality of Aveiro to redesign the central part of the city, based on a scheme drawn up by the Office of the Director Plan. This proposed urban renewal sought to answer an idea of modernization and affirmation of a city in economic and territorial expansion.

Betting on the peculiar features of the urban landscape, the proposal promotes the binding of the two parts of the city separated by the channel, through the redesign of bus routes and pedestrian circulation around and perpendicularly through the arrangement of the block from the Republic Square. Moreover, it proposes a square tower (the medieval style) base to accommodate new urban programs (hotel, offices, commercial centre, car park) worthy of a city that wanted it to be modern.

The development work focuses on the design of the relationship of pedestrian and road, bridges and the contact of the buildings with the ground paths. The relationship with the surrounding buildings is carefully designed with games and openings volumetric gradations in order to provide continuity with the public space.

However, while it worries about spatial continuities, this proposal has aspects of rupture with the existing. First, because it eliminates all the buildings on the block located between Republic Square and the canal, with the exception of two bank buildings (symbols of economic power). Then, because it proposes a typology of the tower that had to change the relationship with the existing space.

Nevertheless, it resumes the typology of the medieval tower, a building that stands out as an architectural element of extreme functional and symbolic importance. In this case, the resource to some references and architectural typologies (at a level of abstraction) helped formalize the general intent of the intervention, enabling action on the form (reality). In this case, the use and understanding of history is an important design tool, serving as a reference and stimulus for formal implementation of the proposal. The discipline of history was used by Fernando Távora as design tool, showing clearly the Vidler idea (2003) where the history is understood not as a problem for the architecture, but as the solution.

I was in this way Távora projected the idea of a new city, while reconciling intentions of modernization, renovation, revitalization and concerns of urban growth and expansion, always with a particular sensitivity to recognize and enhance urban specificities of Aveiro. Those specifics that make it a unique and at the same time a part of the design of urban space Portuguese city.

Figure 5. Barredo's photos.

Methodological experience

The Study of Barredo's Urban Renewal, from 1969, was a pioneering experience in renovation and rehabilitation that served as an example for future action in areas of recognized cultural and historical interest. It expressed all kinds of concerns that resulted of the paradigm shifts that emerged with the post-war and established a laboratory for experimentation on methods of intervention in the city (Moniz, Gonçalves Correia, 2013).

First, because it involved a team effort consisting of the Planning Office of the Oporto City Hall, the office of the architect Fernando Távora, the School of Fine Arts of Porto and the resident population in the neighbourhood. The possibility of a multidisciplinary work arose from the Teaching Reform of 1957, with the implementation of a new curriculum and the creation of a research centre to support research and the profound transformation of teaching methods in architecture and objectives of training of the architect.

Then, because it presented a revolutionary proposal, against the modernist tendencies of demolition and construction of new buildings as a solution to the serious problems of lack of salubrity of the old town. Instead, Távora proposal was to maintain and improve the existing spatial conditions, considering Barredo an integral part of the city and, therefore, an important area to conserve and rehabilitate.

In this sense, he consolidated methods relevant to the project-development analysis, making an exhaustive survey of the neighbourhood, through population surveys, using drawing and photography as tools to know and understand the reality. The information was organized in grids of observation, analysis and interpretation. Regarding the graphic part, represents the ratio of the block with the surrounding context; architectural aspects and interiors of houses in 1:200 drawings; he focus on the block level, exploring the systems of spatial organization of

vernacular construction; redesigns the interior spaces of homes, providing them with toilets and kitchens.

Through a real experience, he reclaimed the social function of the architect in Portuguese panorama, showing a completely different positioning of the architect for the time. In addition to technical and artistic skills, the architect was now understood as an agent capable of acting on behalf of social causes through interventions in the built environment underpinned by a process of human knowledge and spatial problems of the community. A work of architecture is thus a work of collaboration with ethical responsibility to integrate the diversity and uniqueness of urban culture, because people's relationship conditions and is conditioned by the space they inhabit.

Urban strategy: density

Another example of a General Urban Plan is the one of Guimarães in 1982, commissioned by the city to the Fernando Távora's Office, in 1979. Twenty years after the study Montemor-o-Velho, the plan of Guimarães was inserted into another political program of urban management that created the Local Technical Offices in the municipalities with the aim of forming multidisciplinary teams, depending on the municipal offices would ensure the preparation of studies, projects and actions to prepare renewal operations and maintenance covered.

It was the moment where Fernando Távora tried a new approach to urban territory through an analysis of the evolution of territory to various historical periods, beginning with Castro period to the current state, synthesized in eight plants. In Castro period, he sees the logic of settlement of the first people in that territory; in Roman times, he recognizes the importance of roads in the beginning of the urban formation; in the period between centuries IX to XV, he observes the logic of medieval pathways integrated in door systems of the urban centre and distribution network of churches and hospitals; in the seventeenth and eighteenth centuries period, he marks the manors, churches and convents extramural guiding the process of urban expansion and expressions of social, economic, cultural and spiritual comfort of the population with space (Távora and Ferreira, 1982:39); in the nineteenth century, there is new mark in the territory with the railway line and administrative rules to sort and delimit the urban area; in 1950 there is the consolidation of peripheral cores and the consequent abandonment of the urban centre; in 1975, the morphology reveals the serious problems of urban dispersion disorder; in the Predictable Evolution plan (name of the last plan) Távora anticipates the future design of urban sprawl detecting the ways that you can work to redirect the city back to its centre.

In addition, he makes a geographical analysis of the city located in *Vale do Ave*, a fertile region for crops, located in a mountain and valley system; he reunites all the urban plans carried out previously, collects data and promotes questionnaires to the population.

He aims at realization of a "territorial plan that intends to establish lines of development and use of the physical world and not a plan for economic and financial development or a social development plan. Thus, it is a plan that, not forgetting the constraints of road character that mark the territory, focus mainly its physical form and proposes ways to shape their future; or even a plan where the quality of form is considered as a fundamental determinant of quality of life." (Távora and Ferreira, 1982:4)

In general, as a methodology, aims to recognize the process of formation of Guimarães identity through the shape, de-constructing the process of memory construction of that body through registration of permanence and history, in order to give it continuity and find memories that promote recognition of Guimarães' citizens with space, contributing to building a positive identity of the city.

The great proposal of the General Urban Plan of Guimarães is a ring road, scoring entries in the city as doors. This system would work as a wall, and as part of the consolidation centre, referring to the medieval road structure represented one of eight plans of urban evolution, listed above. Távora also prepared detailed plans, in which he draws the "new doors" of the city, and

proposing the rehabilitation square to square and the rehabilitation of some residential buildings, serving as an example for future private investment.

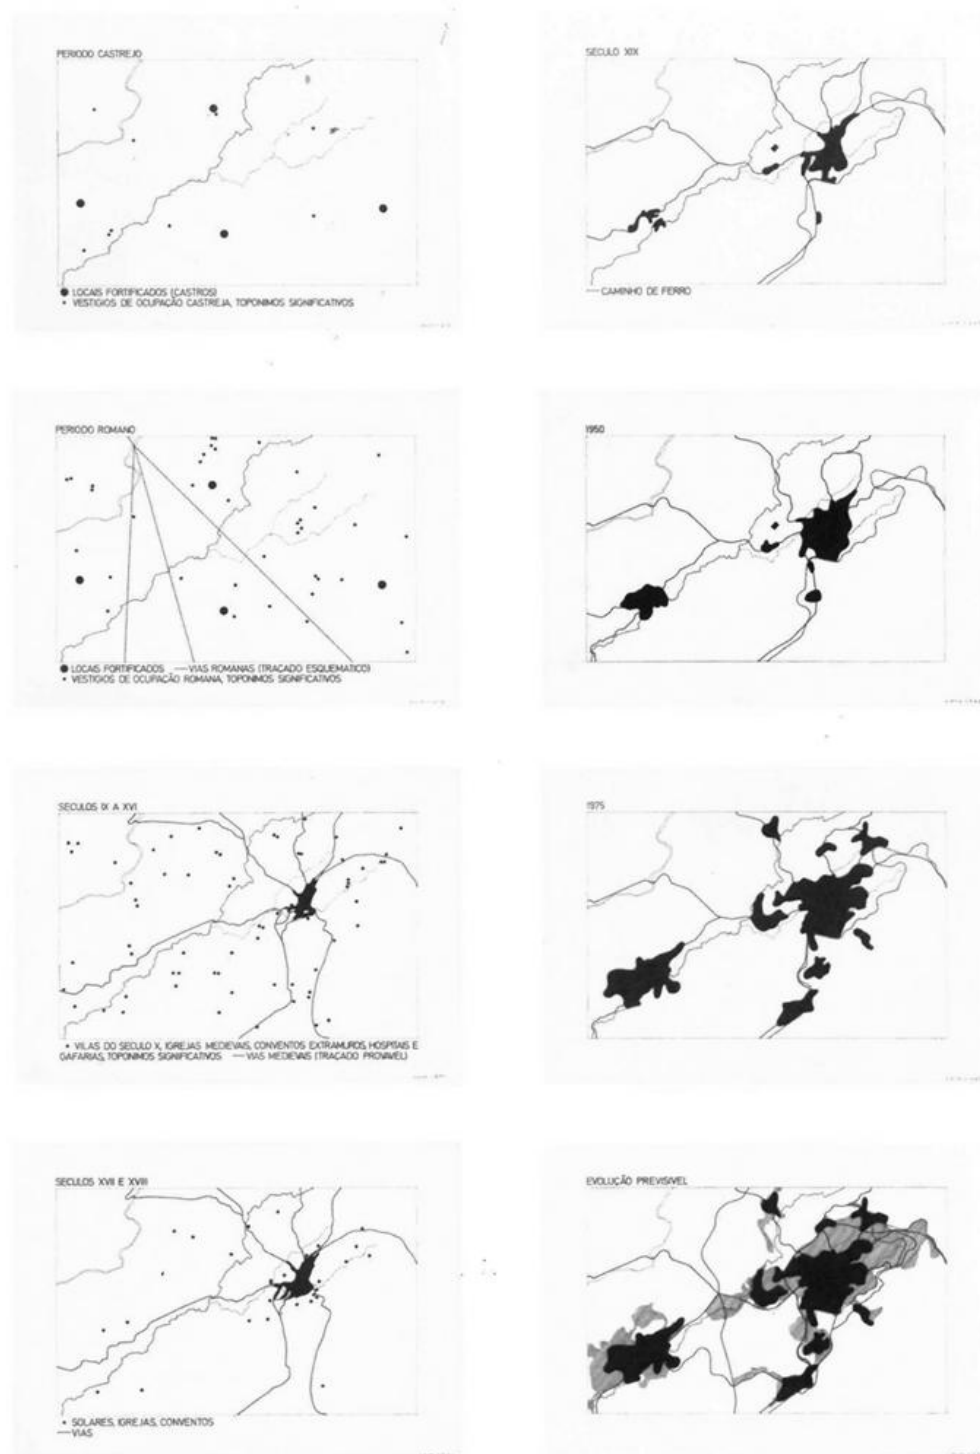

Figure 6. Urbanization General Plan of Guimarães. Plans of the urban growth historical analysis.

Thus, an engine of contamination was created, respecting the natural time for a real change of the urban system, because collective structures and tools were created, serving as positive guide to future choices.

Overall, these interventions intended to promote densification and consolidation of centre city and redirect it to the centre, controlling its form of growth and expansion.

However, the figure of the Municipal Master Plan turned out to counter the strategies previously advocated by Fernando Távora. Since the 80s, not only in Guimarães, the Portuguese territorial planning was promoted by such plans, where the city came to be structured according to the way of mobility, networks, infrastructure, a way of thinking systematized and sectorized territory, encouraging urban sprawl and large-scale planning, thinking about the city in extension.

The territory was resized and urban systems began to function as diluted and fragmented bodies in urbanized territory without limits or boundaries, essential to a cohesive and spatially defined tissue. This rational of thinking about the territory overestimates the functional and economic issues instead of cultural issues, because these introduce management models difficult to deal with inclusion and exclusion, connections and disconnections between groups and individuals.

Despite this, Fernando Távora could still carry out the design of the road node of Creixomil and rehabilitation of a system of squares, as part of an intramural route, thereby contributing to the much-desired centrality and consequent revitalization of urban life of Guimarães.

Figure 7. Urbanization General Plan of Guimarães. Routes and Public Spaces, undated.

Figure 8. Creixomil Viaduct, Plan, 1986.

Figure 9. Condessa de Juncal and João Franco Squares, Sketches, 1992.

(Re) design (Re) order (Re) orienting

The experience and success of interventions in Guimarães, paved the way for urban arrangement of *8 de Maio* Square and its surrounding area in Coimbra. In the last decade of the twentieth century, following a series of restructuring measures in the downtown area, backed by urban policies aimed at solving some of the urban problems and create dynamics for the city by promoting local programs such as Polis Program and Metro Mondego. These programs favoured the revitalization of the city from specific themes to promote multifunctionality, pedestrian areas and to limit the automobile traffic.

Thus, this proposal aimed to recover the initial level of the square reconstituting the reading of Santa Cruz Church dated 1131, referenced to the streets that used to flow in frontal to the monument facade and remove motor traffic on this stretch.

If in the case of Guimarães, the intervention of Távora was "invisible", in a sense that it lets the form speak for itself, that is, limiting to take care of the elements that compose the squares and buildings from different historical periods, respecting the vernacular architecture and permanence of urban typologies that have always been part of the collective memory of a city, in the case of *8 de Maio Square* the intervention focused in a deeper way of resetting, changing relationships with existing morphology.

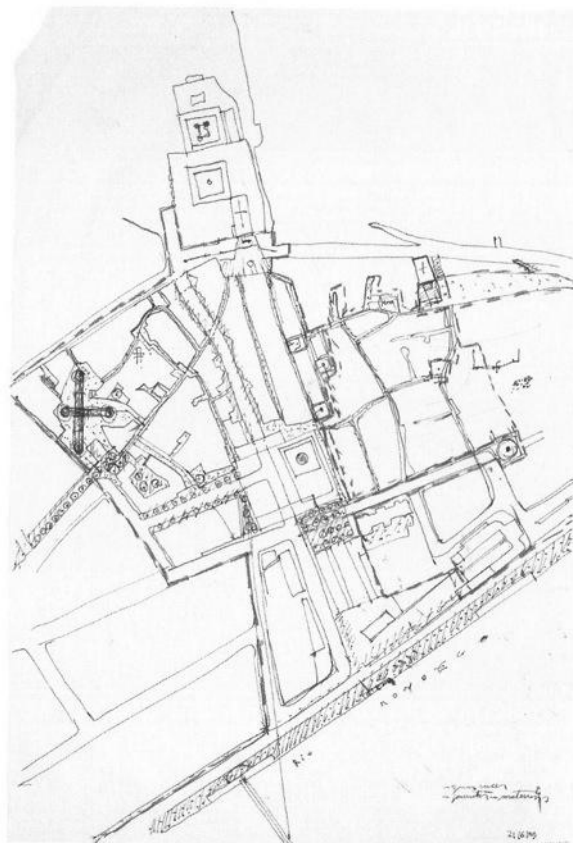

Figure 10. 8 de Maio Square and involving area, Sketch, 1993.

In this medieval urban morphology with irregular features, Távora will pursue a rigorous and careful formal composition method based on the principle of symmetry, which constructs a system of proportions that sets the dialectic between the parts and the whole, as a way of control and spatial stabilization to reorient and organize the physical space of the downtown centre of Coimbra.

To give back the of Santa Cruz Church its centrality, resuming the relationship between levels of the church entrance and the space of the square, organized by two lateral churchyards at the highest level of the streets. The connection between levels is made by two ramps, directing urban morphology towards the river. In addition, Távora proposed the implementation of a water fountain in each of the squares, setting the limit of its intervention. Thus, he sought to unify the surrounding urban fabric.

As in the squares of Guimarães, the materialization and image of the squares was built using native materials. In Guimarães, the granite rock of the area was used and in Coimbra the intention was to use Ançã stone, the same used in the facade of Santa Cruz Church. In both cases there was a careful design and placement of the stones, introducing power lines to direct the "promenades" and stabilize the shape, continuing the plan of facades on the floor. This plastic unification (an architecture "trick") intends to create a stable, solid, robust environment; a space of symbolic presence for the city life meeting.

This project found in classical rules a path for the formalization and realization of this urban piece. It brought uniformity and spatial clarification returning to the original character of "square" as public space with features that promote the centrality of the meeting and a better adaptation of city life to its physical space.

An (Architectural) Urban Project

On very work, Távora experienced new approaches to the city, visible in how it was investigated, in how he developed a narrative about each particular city, in how he explored the graphical work and the way he suggested pivot points of the city with territory. Távora had therefore developed a method to design and solve architecture's own problems, building a line of thought, which persisted among us, the schools of architecture where he was influent, having immediate implications of the development of architecture in Portugal. He also contributed to "a generation who considers criticism and history as tools of project that sees architecture as a process of knowledge, and refuses to separate theory and reality" (Montaner, 2001:139), while realizing that there are aspects of tradition of architectural theory that guided the past and remain essential today (Hearn, 2003).

Urban projects he developed integrated works, which his office garnered, working on them the same way he worked on building projects. These experiences and his training from school of Fine Arts in Porto allowed him to test approaches to urban design, proposing ways for architecture to act, seeking transformation of urban reality, by a methodology which was applied not only to the city but was generalizable to building projects.

In a text from 1957, "Casa em Ofir," Távora reflects on the complexity of the designing process of a detached house, where he aimed "(...), that it would result in a true compound, and, more than that, a compound in which a multitude of factors took place, variable value, indeed, but to consider every single one of them. That is, unlike the normal unfortunate case of caring mixtures of only a few factors, Távora tried here a composite of many factors. It's not easy, of course, list them all, given their variety and their number, nor is it easy listing them in order of importance".

The projects have always had implicit a work of criticism in order to uncover the roots and history, the theories, the way things work and organizations (or disorganization), contained in each city and its territory. From a diachronic reading Távora developed a synchronic reading, extending the interpretation of values, connotations and contemporary creations as temporal continuity, predicting the social impacts of options for the collective memory of the city. Therefore, he constructed a critical project methodology, since it is clearly a forecasting work. A future betting line is defended by the adequacy of urban form to the general requirements of the city. It starts from a problem and continues attempting to approach, suggesting and outlining possible paths and solutions across a broader vision that crisscrossed and connected multidisciplinary referrals.

Believing that the architect should take a more activist stance towards favouring the effective practice of changing reality, rather than purely speculative activity, the working process of Fernando Távora maintains a methodological stance of greater relevance to the present: act locally. According to global strategies, establishing relationships and continuities, or in other words, act surgically promoting an effect of surrounding contamination. This thesis argues for a more socially oriented practice in response to the uncritical position as the city as a mere cluster of complexities and contradictions that prevents the successful architectural practice.

On the other hand, Távora suggests a disciplinary way which reacts to major general urban plans and regulations for urban management as tools used for development planning and urban culture. In fact, for ease and convenience of thought, these tools have tended to simplify reality in order to understand and master in its entirety, considering the territory as a network or mesh. However, these tools made it harder to read the object from the outside, opening the possibility for another type of (non- explicit or literal) spatial relationships and awareness of the existence of an affective and emotional space that influences the form of more or less empathetic relationship with the place and creating memories (Caruso, 2001:13). He also ruled out the possibility of developing readings and images of the city that promote the identification of space with people, a territory of several layers built on continuity or rupture with the urban collective memory (Corboz, 1983). Thus, the domain of the territory is present in its parts, in the local interventions.

Urban agglomerations are nodes of a space organization according to human relations. Because each city is unique, attention given to each case requires rational, analytical, emotional involvement and at the same time, sensitive to their distinctive features that give name to each of them. As mentioned Orlando Ribeiro (1969: 66), "a city is always a creation, a key element of the organization of space, a node in the mesh voluntarily or spontaneously established relationships between people: an inscribed human work on a piece of ground, a fact of surface of small size but of greater significance for establishing connections. Trying to explain a conurbation is, first, enter it at this complex context (...). " The city is built by asymmetries, contrasts and discontinuities, which results in complex ways that do not let them sort themselves by theoretical models, or interpret geometrical models.

In this process of understanding and analysis of cities, Fernando Távora showed the importance of the architecture to develop new readings on urban reality, from main planning methodologies, aimed at solutions more effectively able to modify the social and political structures of the world. Architecture controls and directs the results of architectural practices in solving spatial problems of an object that "is conditioned in its preparation and conditioning in their existence"¹¹⁰ with the aim of organizing human relations.

The spatial relationship has become an important principle to devise new ways to build and refine the design of urban space, understanding that the relationship that man has with space are essential for defining boundaries and construction of their surroundings.

"This notion, that is so often forgotten, that the space which separates - and connects - forms, is also a form itself. It is a crucial notion, because it is what allows us to gain full awareness that become no isolated forms and that a relationship exists always either between the ways that we occupy space, or the space between them that although we do not see we know we can build forms - negative or model -. From apparent forms "(Távora, 1962:12).

The power of architecture is, thus, in its ability to irony, in its ability to relate opposites. Finding order in disorder; to focus on the ruptures and dissonances and asymmetries of reality; seek harmony and continuity; become predictable in the unpredictable and predictable in the unpredictable; transforming truths in its opposite and illogical in the obvious. It is the ability and capacity of Intelligibility architecture that gives the power "to speak in silence and to touch the senses as well as the mind" (Curtis, 2012:131). Ability to depart from the rules, creating space for innovation and creativity. Capabilities that is implicit in the dimension of the immaterial and intangible of human thought and emotion, together with the domain of relations of theory, history and criticism, learning from the past, thinking about the present and projecting into the future.

For all this, methodological consistency in Fernando Távora opens a field of research on project methodology, which undoubtedly contribute to a new awareness of the problem of Portuguese intervention in urban space.

Fourth dimensions urban morphology. Urban geographies of work as a new perspective of urbanity.

Daniel Screpanti¹, Piernicola Carlesi²

Abstract. *New freedoms of individual choice and new possibilities of displacement in space and time of men, information, goods and energies have not liberated the «human condition» from all 'fears'. In contemporary urbanizations, a big dissociation of modern growth can thus be observed: the endless technological satisfaction of consumers' needs is not deprived of «uncertainties». If we consider contexts where preindustrial spaces, without work perspectives, and postindustrial activities, without urban features, are interacting, as in Italian urbanized systems containing small cities, the evolution of territorial relations seems clear and a new issue for urban morphologists is emerging. The Securitas value is now migrating from cities to new geographies of work. From this process, an exponential increase of «divergences among cities» emerged and is leading to inequities among individuals more and more difficult to spot and manage. If the reinforcement of globalization will bring new data on distances between new and old urbanizations, in front of the responsibilities of urban morphologists about the formation and growing of social inequities, we could draw a new perspective of urbanity only by tracing 'the work of cities'.*

Key Words: globalization, land use, social exclusion, maps, urban form

'From Medieval to Global Assemblages' (Sassen, 2006)

The spread on the territory of the most modern production sectors combined old settlements, new polarities, lands and infrastructures producing what can be defined as the modern growth of «rural landscapes», or the extension of the urban economic action to the (formerly) rural areas (Sereni, 1961).

New energy sources and more rapid and less expensive transports, after having made «non urban industrial settlement competitive with the urban one», allowed workforces to be recruited either in the cities than in the countryside (Portas, Fernandes Sá, Afonso, 1990).

In this way, the «city outside the city» was released from the constraints of proximity and spatial agglomeration (Fantin, Morandi, Piazzini and Ranzato, 2012) and the spreading of activities and people on the territory have been progressively superimposed by new territorial dynamics due to the reinforcement of globalization and free exchange of capitals and goods.

The activities of services to companies and to consumers in such a context became essential and in terms of growth established the predominance of some cities on the others (Sassen, 2010).

In an initial phase, the vertical growth of advanced tertiary economies saw the F.I.R.E. economy, based on Finance, Insurance and Real Estate activities, to feed on with infrastructural «kits» and public investments of Welfare State (Domingues, 2006). Following to the diminishing of public resources and to capitals global redistribution, some sectors of advanced tertiary, however, failed while others oriented, by sector, towards new market lines and, geographically, towards more dynamic territories inside the «new geography of work» (Moretti, 2012).

From this process, an exponential increase of the «divergences among cities» emerged and is leading to inequities among individuals which are becoming more and more difficult to spot and manage (Ascher, 2003).

The work as a privilege and the loss of *Securitas*

The distance from the reality of contemporary urban design, has ascribed to urban morphologists strong and specific responsibilities for the current increase in disparities between rich and poor.

The ability of urban morphologies to counteract emergence or increasing of social inequality has been also questioned, because of ineffectiveness of analytical and design methods that we are currently able to offer (Secchi, 2013).

The «new urban question» probably requires a new investigation of relationships between economy, society and territory. For this reason, it also needs to reconsider disciplinary «common values», such as technology, mobility and ecology, which have always built objectives of urban design.

«Socio-technical devices» (Allenby and Sarewitz, 2011), that brought new individual freedoms in economic exchanges and social relations, have allowed people to make incessant demand for goods and services but have not strengthened and stabilized the «human condition» (Arendt, 1964) in the globe as it was assumed.

The opportunity to imagine and satisfy infinite needs has generated «uncertainties» (Bauman, 1999) and divestment, outlining contents of a global crisis of production.

The major dissociation of growth is therefore observable in urbanized contemporary systems where the production of well-being satisfies «extendible needs of men» (Einaudi, 1933) and, at the same time, creates work uncertainties.

In the evident collection of economic injustices and territorial discriminations and exclusions, «the work as a privilege» (De Masi, 2001) emerges as a new issue for urban morphologists (Figure 1).

Although the work is an essential condition to humanize an environment, in the past decades it has been forgotten in the construction of conceptual problems and practice of urban design.

The current gap between wealth and poverty, is an effect of the «new geography of work» (Moretti, 2012) rather than a cause of the «multidimensional character» of the crisis, crossing major economies of the planet (Secchi, 2013).

For example, this is especially evident in Italian urbanized system containing small cities (Figure 2).

Here, there are radical effects in terms of «divergences between cities» (Moretti, 2012) due to transition from preindustrial, or «third Italy» (Bagnasco, 1977), economy, to the current postindustrial.

Right where spaces without work perspectives and new activities without urban features, are interacting, contemporary relations between work and territory, can be seen more clearly than in other situations.

From the beginning of the Industrial Revolution onwards, these interactions have always resulted in new urban issues and, as a consequence, in different policies and urban perspectives for the cities.

Up to this time, in a globalized environment characterized by loss of centrality of States and their ability to regulate social and economic processes, analytical and design devices have failed in order to reduce uncertainties.

In the considered contexts, «spatial forms of injustice», «consequences of climatic change» and «mobility as a citizenship right» (Secchi, 2013) are more and more effects of contemporary geographies of work.

Here, urban morphologists have the opportunity to design a new urbanity based on a modern *Securitas*: a new individual freedom of action in space and time.

Figure 2. Preindustrial and postindustrial, central Italy (Photo: Cnes/Spot Image, DigitalGlobe).

«Il bel paese ch'Appennin parte e 'l mar circonda e l'Alpe» (Petrarca, 1336)

Italian small cities have been hit by the modern economic transformations later than big cities, although, in some cases, they have had modifications even higher in terms of speed and intensity.

We have chosen these urbanized territories as our field of research, because similar situations offer a big opportunity in order to observe the link between new productive models and evolutions of urban morphologies.

In addition, social and economic degenerations faced by small cities, have provided a test bench for our research regarding 'urban geographies of work' as a new perspective of urbanity. In these contexts, the recent changes of economic models has activated processes of desertion of the physical production of materials and objects in favor of a network system for productions of ideas and services, typical of postindustrial economies.

We observed in small cities that the new dynamics have not found the same materials of big cities to pursue their objective and have been progressively characterized by breaking up into two parallel and distinct phenomena.

On the one hand, we have identified a first process consisting in the extension of new dynamics on territories, mostly beyond their geographical and historical circumstances.

On the other hand, we have found processes regarding a progressive reduction of preindustrial activities (Malanima, 1995). They had represented local economies for centuries, allowing in some situations the «industrialization without fractures» of rural territories (Fuà and Zacchia, 1983). If the first phenomenon seems to be related to the innovation of productive cycles, aiming to ride over the restricted areas of traditional productions and to find new markets, the second phenomenon should be linked to a new business dimension, finding its target in tourism and in a systematic exploitation of the cultural heritage (Marini, Bertagna and Gastaldi, 2012).

Beyond the above-mentioned differences, both phenomena share a common trend: the contraction of the spatial field of activities and the territorial extension of the firm size, searching the biggest cultural influence or the cheapest productive organization.

Figure 3. Bazzano Industrial Centre, L'Aquila, Italy (Photo: Cnes/Spot Image, DigitalGlobe).

Figure 4. Lorenzetti, A. (1339) Effetti del Buon Governo in città e in campagna, Palazzo Pubblico of Siena, Italy (Photo: Wikimedia Commons).

From spatial to reticular connections

Checking the relevant transformations of Italian small cities, we have immediately noticed clear differences between new situations of neglect and disuse and similar cases in the past.

Precisely, observing differences with the progressive emptying of these contexts during the postwar period, we noticed that, today, disused socio-technical devices are not isolated but close to other 'facilities' currently operating (Van der Ploeg, 2008).

In addition, this status presents several dissimilarities with situations of disuse in big cities: the potential intensive use of abandoned areas is not effectively the same.

The mechanisms of 'urban income' cannot develop quickly enough, unless there are special conditions of spatial proximity to larger urban areas with solid, diversified and tempting economies. This proximity is often due to a progressive approach to small cities of major ones by expansion or territorial diffusion of their settlements and new accessibilities.

Proximities between different 'devices', and unusual morphological synergies, led us to take a deeper look into the environmental effects of new dynamics.

The analysis revealed a substantial inability of recent transformations to activate new activities in their territorial surroundings. Basically, in the considered contexts, the exchange between new phenomena and the environment is always unilateral.

The new dynamics do not produce new urbanities and exceptionally the new firm size becomes a factor of collective development. Even if new geographies of work have a regional dimension, it's exclusively as scale, because they have not urban features.

The work can no longer be generated in this isolated status and it consumes itself, expanding dramatically in the territory without communicating with it (Figure 3).

As we have already said, a clear trend of postindustrial activities is to create dot links with urban spaces (Zevi, 2012). Certainly this relationship makes flexible and convenient the productive organization, but also unstable and unreliable 'the work of cities'.

Postindustrial companies set an extremely uncertain urban model, especially in territories containing small cities.

Towards fourth dimensions urban morphologies

This unstable and unreliable 'urban condition' is clearly exacerbated by an objective weakness that urbanism and architecture suffer even in contexts more favorable than those considered.

We only should think about the difficulties of changing morphological structures and density already defined. Even articulating mix of activities is complicated, without being able to provide infrastructural support for sustainability, communications and mobility.

In addition, especially in small cities, the design tendency is to conceive public spaces only as leisure places for local people or tourists.

In this way, common spaces between living structures have gradually lost some functions that have always had, such as the articulation of productive activities and the connection of those with domestic ones (Figure 4).

Ultimately, we found in the «landscape» (Palazzo, 2010; Baldeschi, 2011) an additional factor of anxiety for urban morphologists.

In these contexts, its socially significant features, combined with its new productive dimension in cultural and ecological terms, could make it become a useful tool for the transformation of urban spaces and the multiplication of interactions between existing activities (Magnier and Morandi, 2013).

Despite the premises, this did not happen because landscape design has been reduced to inclusion of geometries, depleting all the potential of transformation and adaptation of different contexts.

Typical schemes of the architectural composition, as aesthetics protection and mimesis, have oppressed intentions and have prevented the unblocking of new landscape processes and the achievement of new and better economic and social dynamics.

The landscape became a barrier to the regeneration of small cities because the landscape design became a morphological design on the landscape.

It means a design that is based only on the inclusion of objects in static environments. An action necessarily subjected to mitigation and compensation measures.

A similar design does not seem the best way for the identification and definition of new conditions of urbanity.

In fact, the reality is not static but dynamic. Any context we choose, it has four dimensions and to understand seriously the current «human condition» (Arendt, 1964) in different territories, urban morphologists should represent the fourth dimension of urban spaces.

Our traditional representations are not satisfactory because dynamic systems are considered inertial. In this way, our analysis always considers every issue in neutral space-time environments.

But actually cities are excitations of conflicts (Tafuri, 1988).

Sequences and overlapping analysis at different levels could be attempts to solve shortcomings of this approximation, but today only geographies of work offer some guidelines to produce proper studies on urban realities (Moretti, 2012; Sassen, 2010).

From analysis that we carried out on preindustrial spaces, we have developed different conceptions and interpretations of landscape.

Old 'preindustrial mechanisms' have enabled the reconstruction of the evolutions of urban geographies of work and, from the stratification of different processes and their changes, in spite of their fragmentary condition, a description of urban morphologies that differs from usual representations is born.

If traditional methodologies have a perceptive nature and are based on a fixed, or moving, external point of view, our description follows the inner flows of human activities in the landscape.

A similar representation of urban morphologies gives us a new design tool which is able to create new strategies for stabilizing existing geographies of work (Figure 5).

Figure 5. The work of city as a Fourth Dimension Urban Morphology (Authors' drawings).

Change, utopia and ‘the public’: urban transformations and agents of survival in Brasilia and Rio de Janeiro

Thereza Carvalho

Pos-Graduate Programme of Architecture and Urbanism, Universidade Federal Fluminense,
Brazil. E-mail: thereza.urbanismouff@gmail.com.br

Abstract. *This paper addresses changes to the urban form in two different contexts: planned areas and “organically made” urban fabrics. Two different processes of urban transformations are examined. Large scale urban transformations, designed by a few in response to specific purposes, and small scale urban transformation processes made of cumulative individual changes and perspectives. Brasilia and Rio illustrate the argument. This paper argues that vitality, and other interesting good-to-live-in qualities that distinguish a good city, requires a dynamic balance between ruling and allowing changes of different scales, purposes and agents. It comparatively examines processes of change in “organically made” urban areas - shaped by multiple individual socio-economic-cultural-spatial practices - and in large scale planned areas. It examines the ways and means that some agents of change, with different purposes, and resources, have helped to make vital urban tissues survive for the collective benefit of the city and “the public”, while others killed it. Survival strategies were associated with specific agents and spatial patterns of change, driven by forces of attraction, expansion and consolidation. They were found to intertwine with place and time related inherited attributes. Utopian space models have both inspired and justified significant large-scale changes in city shape, associated to a vision of the future with or without collective purposes. The question of how those utopian modeled spaces respond to different forms, dynamics and scales of space appropriation is here discussed. This paper finalizes highlighting ripple effects that different agents have triggered through changes made to the urban fabric.*

Key Words: *urban transformations; agents of change; utopia; Brasilia satellite-towns; Rio de Janeiro*

Introduction

The ongoing research whose preliminary results this paper presents has been partially sponsored by the Brazilian National Research Council for which I am very grateful. It provided the necessary support for the field work to be done and the scholarship of two research assistants, Ana Carolina Maia, whose dedication, commitment and social skills made the case study with the community of Rio das Pedras an enjoyable experience. This text was originally formatted for an opening lecture presented at the Post Graduate Course on Strategic Environmental Assessment, at the State University of Mato Grosso do Sul, Brazil.

The focus of this paper is on change. Change is here understood as a dynamic process that encompasses various phases of transition that have cumulatively altered distinct parts of the urban tissue. Time and space are interrelated in those phases of transition, through various means of attraction, appropriation and consolidation that have successively taken place, and that have made space significant, through human perception.

The process briefly described indicates how interwoven space, time and the public as agents of change, shape the course and forms of evolution of a city (Lepetit, 1998)¹¹¹. In this study, the idea is that the valued permanence of urban forms creates conditions for these to continue to serve other functionalities and to influence in some manner urban growth and morphology while defining the rhythm of change in the dynamic process of sedimentation. They coexist with distinct temporalities, with technological innovations that distinguish them, according to

¹¹¹ “The analyzed processes come from a more remote past and did not end with the steam engine, the train, and industry that continue to interact independently of the arbitrary “periods” that some approaches to urban history define that privilege round numbers” Lepetit, 1998.

different social, cultural, environmental and economic projections for the future, here understood as of utopian nature, of a given society in different times in different spaces. F. Thomas affirms that the “history of cities cannot be told by disassociating the citizens from the concrete territory where they live and which they contribute to produce and transform”. He consubstantiates the understanding that this study defends.

Utopia 1 – “the public”, city modelling and urban change

“The principle of utopia consists in defining a place that does not exist anywhere: designing a space in which and with which a given community will live according to new rules... that means fracturing any connection with the world around, a spatial de-linkage”, Thierry Pacquot, 1999, p. 91.

Social sciences have traditionally resisted the possibility to consider that the physical environment is an operative factor in human relations. Architects, on the other hand, tend to often believe that design by itself can *create* communities and places. Both professional standpoints appear to define the whole system, physical and social dimensions, according to one disciplinary insight. Understanding that purposive actions also establish unintended systematic relations is a crucial insight to understand how urban transformations are socially appropriated by the public and, by the same token, to understand the dynamics of change in the process of city-making.

Studying processes of change challenges disciplinary segmented views and their institutionalized categories of problems and professionals. It also induces different approaches to people and the spatial and functional patterns they define in their environment, how they interrelate, and the spatial and temporal contexts within which they occur.

Utopias have, apparently, emerged in times of significant changes. It often shows man as a major agent of History and master of his own destiny, equality among men, and between the public and their governors. Regarded as a response to an immediate problem, or as an anticipation of the desirable future or even as the fuel of social progress itself, *utopia* could be perceived as going along, hand in hand, with creative desire and wishful thinking with collective purposes. The perception of how the State related to individuals and how it ruled over their relationship to the territory, through specific legal and institutional arrangements were, however, often either obliterated by the very *vision* utopia proposed to illuminate or simply taken for granted as a side issue.

More recently there has been a shift between the trend towards *dreaming* new utopia - as a peculiar form of social ideal construction inspired by universal harmony - towards the more *pragmatic* and *utilitarian* approach where the future heralded is, more often than not, a terrible nightmare. Possible reasons for this shift may lie in the perceived shrinking presence of the National State on the *ground*. Drug cartel networks and other forms of self-government arrangements are allegedly taking over, in some areas in Brazil, as well as, in other areas, new social mechanisms bottom-up devised to rule over individuals and territory.

Meanwhile, to dream of better cities, and to design them - where better individuals would relate to better societies, and to better territories, where nature would play different but always better roles, and the State which would be responsible for universalizing the benefits would then issue better ruling over their distribution - has been, traditionally, regarded as part of the professional privileges and obligations of architects and urban designers. However, as Kevin Lynch beautifully pointed out in the very last page of the *Good City Form* - how defective his presentation was because the city concepts and models he discussed in the book were “too often stripped of the institutions of management that make them viable, and were described as if independent of the culture and political economy in which they must be applied” (Lynch, 1981, p.454). Generalizations are our downfall.

Design guidelines are often addressed ‘stripped of the institutions of management that made them viable’, originally, and, apparently, as a consequence, independent of the culture and

political context where they were generated in the first place, and, also, of the culture and political context where they are supposed to be applicable. What is sustainable in one given culture may prove to be quite the opposite in another context. Significant process of change is therefore required.

Change and dynamic balance between ruling and allowing

The perspective here adopted understands that a singularity (an exceptional condition) once perceived (therefore observers and physical accessibility are required) in one or more of its qualitative dimensions it attracts changes in all the others, in a ripple effect that will reshape the 'townscape' accordingly. Be it a characteristic that defines its exceptionality a natural feature, or produced by sedimentation, or designed from scratch, successfully, to that purpose.

This paper adopted six different perspectives, or genetic dimensions, of the cultural heritage of a city and its grid, and of the process of sedimentation that intertwine them with the lives of citizens and city into the landscape. Together they have influenced the stages of sedimentation, with different weights, in different time and space bound contexts, and distinguished their interrelations as they consolidated.

The first, the environmental dimension, is here understood as one or more geomorphological feature of the terrain - topography, coastline, solar incidence, and climate - which attracts the attention of observers, individual intentions which may grow into collective users in a given time and space context.

The social and economic dimensions follow. They comprehend different forms of appropriation practices and uses of potential values perceived in the area. Market activities and social encounters go hand in hand and they literally make place for more complex events and users who will benefit from their location.

The fourth dimension, here called institutional or normative addresses the rules that establishes the power to regulate uses and users, mobility and public access, the building activity and the built forms and changes allowed. Public sector with bigger or smaller political prestige, its normative and control mechanisms, and symbolic presence in the built landscape, are also part of the city genetic heritage.

The last dimension is morphological and it characterizes the singularity of space and form in the light of a mix of different references - formal repertoire, location in relation to axes of accessibility, quality of building materials, functional and symbolic contents related to the previous dimensions. It synthesizes the interrelations among the previous dimensions in built forms and shapes that tend to last longer than the former purposes to which they were designated. At the same time it enhances them. The many successive uses and built in values that usually follow are aggregated to the area. The relative permanence of these earlier forms and later uses enrich the process of sedimentation of heritage with new interventions, when the perceived image and identity are positively regarded.

Accessibility constituted the basic condition that allowed for those qualitative dimensions to interrelate, with distinct rhythms of changes in different time and space contexts.

Case 1 – Rio

This topic addresses the dynamic balance between ruling and allowing, in practice, as perceived in selected areas in Rio, and what has it improved. The objective was to *qualify* the community for participation in the urban policies announced by the local authority which would be implemented in the borough. In order to achieve that purpose the prospective participants had to be able to read blueprints, and to understand scale. They also had to feel comfortable enough with themselves, in the first place, and with these subjects, to enjoy participating in the public audiences conducted by the Local Authorities. These objectives determined the plan of the

research proposed. It had to begin by strengthening their identity as a community, respecting their migrant origins., their cultural values, and how these values, and their symbols, were reflected in the shape of the buildings and grids of access that characterized the settlement.

The settlement

The settlement selected was Rio das Pedras started in 1951, located in Jacarepaguá district, adjacent to Barra da Tijuca, the urban expansion where the rich suburbia in the shape vaguely reminding garden cities developments are spreading fast. The area of about 130.000 square meters, was officially granted to the settlers by the Government in 1966, as result of their own efforts to articulate with the government. They were mostly employed in building construction by the real estate developers working in the area. Proximity to their jobs proved to be useful. Located very close to rich condominiums, built during the 60's, the settlement grew significantly, through self-help of all sorts, to the amount of, approximately, 70.000 people basically migrants running away from desertification in Northeast Brazil.

Methodological procedures

The area selected for the research was a cluster made by a mix of different building typologies and functions, of housing, shopping, major municipal institutions, the cultural centre represented by the state school and the settlers association, all of which had clear social, economic and political links with the formal city and with the state government structure of Rio. A central open space made into a square with a canopy strangely scaled served as the major visual reference. Not by coincidence three of its margins were occupied by the school, the association and one small office of the local authority. The symbolic content of this area, due to this particular mix, determined our choice.

Interviews, participant observation in different sorts of meetings, and as idle visitors, urban environmental perception and analysis, historic data research gathering photos, maps and previous and present urbanization policies regarding the area, together with a great deal of story listening, made the basis of our initial contacts with the local community and the settlement.

The idea of building a model of the area as an acceptable course through which we could, at the same time, strengthen their identity and teach the school teachers and their students how to read and understand a blueprint was proposed. It was quickly accepted by the chair person of the state school whose strategic plan for the year comprised that specific subject. The teacher of arithmetic of the first grade for adults, accepted the challenge of supporting our initiatives. She also agreed to have me and my research assistant participating in her classes during the period.

A method was devised to create with the students a 'measure' of reference based on the one building in the area that had been architecturally designed – the state school. Drawing the area, maps and facades, exercise done by the various students, proved to be an effective method to raise their self-esteem as they experienced finding themselves in the maze and pointing their whereabouts to their colleagues. Updating municipal maps with all this information brought in through that exercise boosted their self-image even further. The second phase of the exercise demanded that each student would tell his or her story in Rio das Pedras and also illustrate it with drawings, photos or collages with several objects that reminded their common origin in the northeast of the country.

The building of the model came as a bonus. The very planning of the model, defining the scale it should be built, the materials to be employed, engaged and excited students and teachers, empowered by the perspective of explaining it to the Mayor – a significant change in behaviour - compared to their subdued silence observed in the initial public audiences.

Processes of change

Initial findings in this stage revealed that one local leader of the settlers association has gathered enough support to get elected local councillor. He helped to bring local government attention to the

settlement. However, some housing developments built since then show the marks of indifference that zoning based on functional segregation imposes.

The improved skills of the state school teachers and students with blueprints and urban grids, and the importance of mixed functions and building typologies, strategically placed and scaled open spaces, and how the whole lot improves local identity, have come as one important achievement. To collaborate to improve to improve public participation in the management and political process that rules over their city, or borough or settlement, has also boosted the self-confidence of my research assistants. They felt happier with themselves and the research received one of the three annual prizes awarded by the research Council of the University Federal Fluminense, where I teach urban design. The proposed method of modeling with the community, as a means to enhance participation in urban renovation programs, has found some support with other colleagues. But that, certainly, is not the main result of this whole effort.

There were major findings regarding the self-made urban design of the area which need to be further investigated as they surprisingly matches several recommendations regarding what might be considered a sustainable neighbourhood. They indicate further research to be done. They are listed as follows:

- a) The research area had an identifiable centre, the square with the high canopy, easily perceived as a reference point with symbolic meaning as it gathered in its margins the state school, the settlers association, the local authority office (Fig. 3).
- b) Most of the housing units were spread around within a range of five minutes walking distance;
- c) There is a great variety of building typologies, of row-houses, and two and three storey houses (Fig. 3);
- d) Mixed uses fill in the few gaps between buildings, with shops, offices and institutional buildings (Fig. 3);
- e) Several plots had more than one building serving different purposes, small shop or atelier or room to let;
- f) The presence of the school reinforces the singular identity of the area (Fig. 3).
- g) Several alleyways communicate within the block, for pedestrians only, as Fig.3 and Fig. 4 illustrate;
- h) The neighborhood is organized through self-ruling. When and where conflicts emerge they are brought to the local settlers association to resolve. Decision is negotiated with the those directly concerned. The association distributes some form of justice speedily.

Design and dynamic balance between ruling and allowing

Modernist housing schemes and garden cities' concept have not diverted much from the utopic trend of social redemption through town and country planning. The huge housing development schemes for the less privileged or altogether oppressed became the main target – they would, apparently, need to be redeemed sooner. Those schemes also became the image of the under privileged with all the stigmatizing contents associated with it in competitive societies.

Walter Gropius and Le Corbusier recommended urban planning as “medicine for a sick society”. However, more than one planned city, or district, have been severely criticized, and often with sufficient evidence, for the opposite reason – people have been made sick by the urban ‘medicine’. The critique of the model condemned the principles of the ideology at the same time.

Case 2 – Brasilia Federal District

The area of the Federal District of Brasilia was supposed to be occupied only by the cross-shaped Pilot Master Plan. This has been planned and originally conceived, in harmony and order, as a “work of art”. The ‘birth’ of the city was blessed by the creative efforts of some powerful minds, and politically influent, of that time. As “art”, Brasilia was supposed to have

been kept in a flawless frame, with no poverty, no shanty-towns around it, to 'stain' its purity. The theme of this paper, the settlements surrounding the Pilot Plan, were not part of the original project for Brasilia. The battalions of poor workers recruited to build it were not supposed to stay. They had not been invited.

The satellite towns have not been planned in 'harmony and order', but conceived through "rape", perpetrated through means of several foci of rebellions, by the thousands of workers that have come to help making the work of art true and subsequently felt pushed out of the 'picture'. The violence of their birth had been, apparently, tamed by an institutional homogeneous handling of space and shape. Their standardized urban design, the one standard plot – with very few variations from one planned settlement to another – the absent hierarchy of public spaces, the minimal provision of communal facilities, all these factors together indicated the mono-functional approach to the matter of satisfying the rebelled workers' request with a predominantly dormitory-town.

Prevalent approaches

A great part of the analytical work on Brasilia, and surrounding settlements, have been developed according to two trends. Either '*for*' the esthetics of the 'product' and the positive political catalyzing aspect of the 'process'; or '*against*' the functionally segregated aspect of the 'product' and social segregation of the 'process'. The string of the original 'free-towns', around the Pilot Plan, have been expelled to areas further removed from the center, named satellite-towns. These have been legitimized by the Government, through some kind of plotting, gathered in different shapes, and have long outgrown their original dormitory function. The process of historic development of each one of them, and corresponding social, economic and cultural deprivation that characterized the living conditions of the first settlers of Brasilia – the builders – which derived, to a great extent, from this spatial segregation, have been sufficiently examined by several authors such as Paviani (1987); Ferreira (1998); Farret (1985); Cony (1998); Santos (1985) among others, with different political focus.

One important aspect, however, seems to require further attention. The fact that these settlements have been undergoing a continued process of cumulative changes, over the last thirty years, which have transformed very positively certain aspects of the role they played in the region. What are those changes? What do they look like? What kind of initiative, and whose, made them happen? For what or which purposes? What do these indicate?

The objective

This part of the paper addresses the issue of planning spaces vs. making places. The object area comprises Ceilandia and Taguatinga, two of five major planned settlements located around the Federal District of Brasilia, capital of Brazil. The theme is urban design, the focus is on changes, additions and other alterations made by the residents on the original design of the area and pattern blocks. It analyses these alterations, how they have eventually a 'ripple effect' on the immediately adjacent planned spaces and neighbourhoods. The character of these areas, under the impact and influence of these gradually cumulative 'ripple effects', has changed significantly over a relatively short period of time – approximately thirty years.

The vector of change can be traced from Taguatinga, the first workers' settlement officially 'plotted' as satellite, 25km from Brasilia, outwards to the next satellite –Ceilandia. The economic and social rhythm of these two settlements are unparalleled in the Federal District. The original building patterns and urban grid have been appropriated in different ways. The two settlements have grown towards each other, mingled and blended, and have been substantially reconstructed, in many patches, in widely different scales.

The methodological procedure of analysis

The analytical framework was conceived in a different context, and city. It derived from a previous research on performance evaluation of large scale housing estates. It had a similar focus – changes and alterations of the original design, made by the residents. Originally orientated towards a different purpose – identifying the “why’s”, it gradually developed towards identifying the “what for’s and how’s”. The move from one target to the other, by the time of the previous research mentioned, was like turning the focus from the past to the present heading to the future. This move resulted from preliminary findings of that research, which questioned the original assumptions that changes would derive from either design flaw or vandalism. The alterations carried out by the residents showed a much larger span of choice, mostly geared to making productive the available space provided for whatever other original purpose. The major ‘arena’ where these changes took place was the space ‘in-between’ the semi-private/semi-public areas adjacent to the different building patterns. They triggered a process of social and economical growth with minimum State investment.

The analysis focus on three major points. First, it identified the different purposes and related perspectives that the various *agents*, or interest groups, introduced, on their own volition, into the process of making real the planned satellite-towns. Secondly, it tested the assumption that a different shape – and scale – would correspond to a different perspective – and interest group – at different times. The third step was to chose a sample area and to define the approaching scales of observation. Finally the analysis checked whether some of the more specific findings of the mentioned previous research proved valid.

The object area

Ceilandia is situated 35km away from the cross-shaped Pilot Plan of Brasilia. It was created in 1971 by personal request of General Medici, who was then the President of The Federal Republic of Brazil. He was annoyed with the string of poor settlements, also called *invasões*, that ‘lined’ his daily route from the ranch where he lived, out of town, to the Presidential Palace of Planalto. The Governor of the Federal District of Brasilia then started an official crusade with the purpose of removing these *invasões* – the Campaign to Erradicate *Invasões* – C.E.I.. A total of 82.000 people were removed from the area to a site 35km west of the Pilot Plan. The very name Ceilandia springs from the acronym, C.E.I. plus the English originated word land, *landia*, thus making fate clearer: the land of the unwanted ones. Short memory, hard work, and the ‘live one day at a time’ rule, that ever so often befalls Brazilians as the one left possible life-motto, for one reason or another, all together apparently helped to, fortunately, boycott the initial stigmatizing attempt on the town and its residents.

Taguatinga was created before Brasilia, in 1958, 25km from the future Capital site. It sprang from the urgent need to remove a pioneer housing settlement of 4.000 families formed close to the *Cidade-Livre* alongside one major federal road that led to what was then the huge building site of Brasilia. Six months later schools, hospitals, houses for the teachers had already been provided even though planning was never a strong aspect in the process nor had any study ever been conducted on the adequacy of the local environmental conditions. The growth of the settlement took place through plotting new sectors when thus required.

Processes of change

Over the last three decades, the initial settlement of 82.000 people grew to approximately 364.290 inhabitants. It became the largest of all satellite-towns around Brasilia. Constricted by a standard urban grid, with standard plots and plot size, as well as by a ‘residence only’ land-use regulation, Ceilandia has, literally, gone overboard in all aspects. Commercial developments, for different purposes and scales of capital, have spread over, once again, the *planned spaces for public activities*, an grabbed the ‘in-between’ semi-public/semi-private areas, with ill defined

tenure and worse maintenance, that often characterize modernist urbanism as found in Brasilia and neighbourhood. The initial part of the survey for the research whose findings this paper discusses, revealed 1.172 commercial establishments which have been gradually added to the original building design and planned intention for the area as well as 1.110 other irregular appropriation of public spaces for well-established commercial purposes. These changes concentrated in the older and more permanent patches of the town and along the high-street that linked Ceilandia to Taguatinga. The price of the plot in one of these patches can be three times bigger than in any other part of the mentioned satellite-town.

Each type of building in the selected patches, once identified, was mapped and its 'origin' was traced, first in the area of Taguatinga, and later in Ceilandia. By 'origin traced' this paper means the search for the original pattern, when this was the case, and the gathering of its 'family', i.e., its multiple variations brought about through alterations carried out for different purposes. These variations, once analysed revealed a typology of purposes apparently indicating a corresponding typology of perspectives – or non-physical dimensions - of the urban realm which have been, apparently, neglected in the original plans for the selected areas. They were the economic-productive, the administrative-regulatory and the place-making perspectives - or dimensions.

The economic-productive perspective emerged as a matter of consequence of the specific circumstances that marked the creation of the satellite-towns and of Brasilia. The great distances between the Federal District and the main centres of production in the country, distances made even larger by the precarious means of transportation then available, also made 'importing' any goods from anywhere, very expensive, particularly in its first fifteen years of existence. Prohibitive costs stimulated the enterprising initiative and talents of the many migrants that swapped their birthplaces for the desolate paysage of Brasilia early years. They bloomed rather in the neighbourhood of the federal capital than in the capital itself thus indicating the next dimension of the process of change that took place despite all planning: the administrative-regulatory or de-regulatory perspective. Permission was required to change social space perspectives. The severe rules regarding land-use in the Pilot Plan made it very difficult for industry or trade to settle in Brasilia. At the same time, income distribution concentrated in the federal capital made it an attractive market for business (table 1). The average income in Brasilia was three times bigger than in any satellite towns, and the whole Federal District, all together had by far the highest income in the country. Taguatinga was the longest established 'satellite community' with a growing population of desperate fast learners strongly motivated by the previous arguments. The making-place dimension regarding, for the sake of this paper, a space with a perceived meaning collectively achieved came, in the selected areas, as a consequence of the former two.

The patterns of changes identified comprised the initial alterations and their ripple-effects. They revealed a 'coding-system' made of a check-list of features and forces of change which were found to characterize the process of urban configuration of the selected areas. They have been initially tested and acknowledged, in a subsequent research conducted in another settlement, as indicators of local potential for development and self-government, in a process of continued change with minimum State investment. The mentioned check-list included static features such as design patterns, density, scale and size, as well as dynamic features such as forces of segregation, agglutination and polarization. When and where most of this check-list of features of change was found some common performance criteria were also perceived. They comprised: grater accessibility to major trade flux and visibility from these routes; perceived availability of whatever goods or services being offered, often implying forces of agglutination multiplying similar patterns of change in the neighbourhood; where singularity of services or goods being offered, regarded important, was identified it often implied forces of polarization defining new trends of change in the urban grid with strong impact on future changes in the area. Permeability to changes as well as environmental adequacy were also acknowledged as conditions to the desired process of change towards making the original 'satellite-dormitories' into better places. Taguatinga, the oldest settlement, proved to be the spatial and economic

model whose influence and ripple effects have set the standards for change among the ring of planned settlements around Brasilia.

Final considerations: dreams and nightmares

The forces that intertwine new and old space patterns, and meanings, sometimes juxtapose, sometimes overlap and hide, sometimes value and maintain them, sometimes abandon them, contracting, expanding and recreating. They make the city's heritage together with the agents of change that make them happen. They have been appropriated differently, along with various times of sedimentation, by different social groups, adapting to new and old functionalities under distinctive manners and management that rules over its use and changes. The changes introduced in any given era, understood as innovations, leave traces and signs in the 'townscape'. The individual and collective intentions that have successfully materialized into changes, and that are still happening, go into sedimentation, intertwining with new uses and users and public open spaces.

To face the challenge of allowing design approaches that interact with multiple agents of change, future and existing ones, requires the courage to face the risk of messing it up. The ripple effects of negative changes can jeopardize social, economic, management achievements that may have taken hundreds of years to consolidate into a certain level of urban quality environment. Positive changes may enhance value for all. The financial costs of changes in the genetic heritage of social and economic space related processes of city appropriation have yet to be evaluated. Maybe numbers will help those who have the power to redirect present and future investments towards more adequate useful preservation and innovation compatible policies.

Figure. 1. Aerial photo of Rio das Pedras settlement, in Rio de Janeiro, Brazil.

Figure 2. The area of the settlement Rio das Pedras. The circle indicates the area of the research project. Its main characteristics are – it is self-designed, self-built, self-managed and self-provided in justice and public safety.

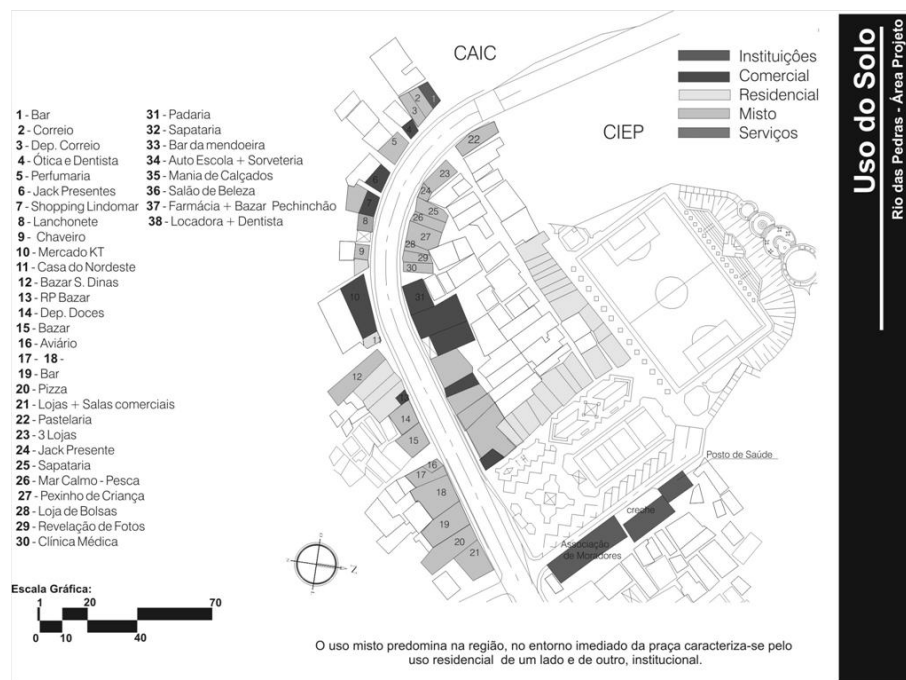

Figure 3. Mixed land uses, functional diversity together with morphological diversity and a clearly marked centre. The presence of the school reinforces the singular identity of the area. Several alleyways communicate within the block for pedestrians only as figure 4 illustrates.

Figure 4. The left poster in the photo indicates that bicycles and motorbikes are not allowed. It illustrates how the community of Rio das Pedras exercise self-ruling over the open space. The absent State is there replaced.

Figure 5. The model of the borough made by the students of the CIEP school as part of this research project. They are young adults, migrants, originally illiterate, beginning to learn reading and writing and basic arithmetic.

Figure 6. The model and the aerial photo of the whole settlement. It was exhibited in an open fair sponsored by the Settlement Association. The mayor of Rio and other Local Authorities representatives participated in the event.

Public involvement transformation for best future of cities in Russia

Mariia Zakharova, Tatiana Gudz, Ekaterina Meltsova

Perm National Research Polytechnic University, Russia

E-mail: zaharovami@gmail.com

Abstract. *At recent years, the distrust of the government has intensified in Russia. It showed up in the criticism and denial decisions of the federal and local level authorities, including municipality development issues. This fact makes strategic urban planning a complicated and unenforceable challenge. Public discussion of the city strategic development is a mandatory part of the document approval. This measure is set forth in federal and local legislation. However, despite the enshrined laws, the quality of public debate still stays extremely low, and the results are not credible. Partly due to the Russian mentality, partly to the procedure of public hearings the event itself aims just to inform about upcoming urban life changes, but not to affect the decision. World experience of public participation illustrates that this approach to decision-making practice is beneficial for all urban participants: increases the trust level for local government and prevents future disputes, identify the real city resident interests for potential investors and land owners. Using the results of public hearings on General Plan Amendments, we propose to amend the public hearings procedure for the urban development projects in Russia. General Plan of the city of Perm is the main strategic document that regulates the urban development for more than 20 years. These public hearings focused on land use of significant city areas, such as the relocation of the Zoo into the urban forest, new outland district development for 75 thousand people (10% of the city's population), shopping centre development on the central city square - the Esplanade. Perm is an industrial city with a one million inhabitants, one of the first cities in Russia conducting urban policies based on the new urbanism ideology. Using the experience of public hearings in Perm, we identified the problems and "bottlenecks" of public participation. This experience gives us the opportunity to make recommendations for improvement of the decision-making procedure in urban development.*

Key Words: *public hearings, public participation, strategic documents, decision-making, surveys, new urbanism.*

Perm is located in the east of the European part of Russia on the Kama River and is a large diversified industrial, scientific, cultural and logistic center of the Urals with a population of one million people.

History of the city begins in 1782 during the reign of Empress Catherine the Great. At the beginning of the XIX century were defined the basic principles of the structure of the city. Like many cities the layout of which was produced in the period Perm received direct perpendicular streets and broad avenues with a high level of diversity of historic buildings with samples of almost all architectural styles and trends that had spread in pre-revolutionary Russia. In the postwar years, Perm grew all new residential neighbourhoods on both banks of the Kama River.

Documents the strategic planning of the city (in Russian it called General plans) developed since the founding of the city. In Soviet times such documents in Russia developed large urban institutions using the same approaches to various Russian regions, which actually led to the decrease in the role of spatial planning.

City development strategy simply reflected the next administration's plans for the building of new housing estates and industrial areas provide. With all the social benefits realized in strict accordance with the regulations and adopted at the state level typological series. These measures are used during the Soviet years and led to a general decline in the quality of the medium and the appearance of the same neighbourhoods with a whole set of problems.

In addition, a growing sprawl of built-up area of the city has led to an increase in cost the city budget for infrastructure development and improvement that affects the state of the economy of the city. In turn, the reduction in the level of development of the economy provokes outflow of human resources with those of the city, where the number of opportunities for the development is greater.

For these reasons in 2008 the Government of the Perm Region decided to develop a Master Plan for the city of Perm, covering questions of city's development strategy for the long term. The decision was the first example of the development of such a document in Russian and formed the basis for the development of the 2010 General Plan for the city of Perm - document the development of the city under the legislation.

The main principle of the Master Plan and subsequent General Plan was the failure of extensive development in favour of the development of the city within the existing boundaries due to the large-scale redevelopment areas.

Thus, Perm got an opportunity to increase the quality of the urban environment within the existing boundaries and create conditions for the effective functioning of the urban economy.

That's why large construction companies have lost the right to build up new territories and urban forests, the level of protection which was increased in these documents.

In the context of a change of government in 2012, the city has been a weakening of urban regulation that allowed developers and the administration to apply for a change in the General Plan of the city of Perm. In 2013 17 such applications were submitted by the city administration to a public hearing held in the period from 05.11.2013 to 28.11.2013. For Russia, a public hearing is the only legal way to get involved in solving urban problems for residents.

Public hearings on the changes in the General Plan aroused great interest on the part of all stakeholders. During the discussion of draft amendments have been collected more than 1,500 complaints of city residents, their number is three times the number of applications received in the discussion of the General Plan in late 2010, which attracted just 452 treatment.

The study was an analysis of the quality of public hearings, with the opening of the problems and the procedure as well as the collation and compilation of hits residents with the aim of identifying and evaluating the relationship to the residents to discuss the proposed project and their perceptions of quality urban environment.

Public hearings are expected participation of citizens in the following forms : 1. Appeal filed in writing to the Department of Urban Development and Architecture Perm Administration territorial or administrative authority; 2. Appeal filed in writing, through the Internet reception Mayor of Perm; 3. Appeal filed in writing in one of the official events held during the public hearings; 4. Oral treatment to the audience in one of the official events held during the public hearings.

Residents of the city of Perm got all the proposed forms of participation. Significant amount applied (63% of all applicants) got two forms: oral statement and a written request transmitted to one of the eight activities conducted by the Department of Urban Development and Architecture Perm Administration. Third of the applicants (36%) sent their written requests to the administration of the city of Perm. A small percentage of the applicants took the internet reception Mayor of Perm, working on the site of administration of Perm . Distribution of forms used appeals to all applicants can be traced in Figure 1.

Residents received treatment during the period of discussion projects unevenly. On curves registration applications to the city administration clearly expressed peaks of registered applications (Fig.2). These peaks fall on the date of the events in the areas of the city at 5, 7, 12, 14, 19, 21, 26, 28 November 2013. This is due to the fact that most of the applicants have used the forms of participation in the discussion, suggesting a visit to official events organized by the city administration. Greatest number of complaints registered in the last days of procedural delay discussions projects. This fact requires further study. This may be related to the peculiarities of registration written applications by the City of Perm, and with the escalating interest of citizens to the proposed changes during the public hearing in connection with the debate unfolded in the media and social networks. If the increase in the number of calls in the

last days of public discussion due to the second reason, it can be concluded that there was insufficient discussion term projects that should be investigated separately.

Figure1. Method of filing complaints of residents in the city of Perm administration.

It should be noted that in the last days of public hearings received 136 appeals, identical in content and designed to support all the changes discussed the Master Plan. The share of these appeals is about 9% of the total. In the generality of content applications and the ambiguity of their origin, in the analysis of complaints of residents they were placed in a separate group.

Figure 2. Schedule registering complaints of residents.

Projects change the General Plan of Perm offer changes associated with the form and content of the General Plan.

The first draft contains changes that lead document in accordance with Russian legislation, changed since the adoption of the General Plan in December 2010, and offers to put a grid on the base maps / diagrams to simplify working with them. However, this project contains changes that significantly affect the goals and objectives of the document, leading to a levelling the strategic planning and development of the city.

Second draft amendments prepared by the proposals received in the administration of the city of Perm municipal government authorities and landowners. All proposals relate changes in the functional areas of destination. On the proposals of the applicants was formed 17 changes the Master Plan. Suggestions included changing the zoning of different types of areas: residential, recreational, commercial and industrial.

Due to the differences between the proposals in the size of the territory, their social value, changes caused by different response from the residents. Rating Comments proposals shown in Figure 3. The most active residents spoke against the territory of Chernyayevsky Forest - large

forest within the city, the second highest rating by a wide margin took Esplanade - extensive free area, located in the city centre. Then follow with a relatively small number of appeals in the river valley area Danilikha who wish to build up the developers, the territory of the former airport "Bakharevka" suggests a developing neighbourhood in the 40,000 residents in the new territory. Following were rated territory, located on the border with low-rise buildings Iva -1, 2. Other changes General Plan Perm caused less significant response from citizens and are not considered in the ranking.

Figure 3. Rating comments proposals to amend the General Plan.

Within the protected landscape Chernyayevsky Forest, located in the city showed the importance of territory for the residents of the city of Perm. In the administration of 963 received treatment (about 62% of the total number).

The main objective of the zoning change was the transfer of the territory in the Permian forest zoo. Currently Zoo is negligibly small area of 2 hectares in the center of Perm. The question was raised repeatedly moving it once and has already received the decision on placement in one of the areas of the city. In accordance with the decision of the Spanish firm Amusement logic,SL drafted zoo. Subsequently, the decision was reversed and the administration has proposed for the zoo territory Chernyayevsky Forest. According to the results of the hearing majority of residents (58%) was not in accordance with the changed plans and administration insisted on keeping the current usage. Supports changing the intended use area is transfer the Perm Zoo, only 38 % applied. About 6 % of the requests contain proposals for alternative uses of this part of the territory.

Distribution of calls for an exemption of the proposal of the draft amendments to the General Plan has addressed the place of residence shows enhanced activity of resident's adjacent administrative areas. It is understandable that the said area fulfills recreational functions and is involved in the daily life of the community. For residents the opportunity to freely use territory forest park is valuable because their normal life is inextricably linked with the forest. Changing the functionality of the site will reduce the comfort of living in areas adjacent to the territory of the possible deployment of the zoo. On the other hand the situation of resistance increase in the activity of using the territory expected and occurs when discussing the possibility of placing any large urban sites (the tendency of "not in my backyard").

The main reasons given in explanation of position 'delete' are shown in Figure 4.

It should be noted that residents of neighborhoods in their applications using the emotional momentum to express their attitude to the territory of the forest park, "Leave the forest people", "last bit of hope for the rest in the neighborhood", "The only joy", "Miracle, existing in our city" and others. This demonstrates a high degree of sensual attachment residents to discuss the project.

Figure 4. The prevalence of the different arguments of opponents of changing the status of protected Chernyayevsky forest area.

The addresses of residents reflected dissatisfaction protracted decision-making process for migrating zoo " should stop already discussing ", " need to take resolute decision " and others. With regard to statements supported by this argument, for the desire to change the designation of part of the territory Chernyayevsky forest to accommodate it for Perm Zoo , may be hiding hope of speeding up the process of government decisions on the construction of significant urban object.

The main reason residents in "voting" for making changes is the desire to have a modern zoo " European level ", located near the city center . Thus, references in support of changes to reveal the significance of the zoo inhabitants, not their attitude to the zoo on the placement of the Chernyayevsky Forest area.

Turning to the cultural context of the existence of zoos in Russia, we can say that culture zoo itself is not deep Russian tradition, unlike the culture of theaters or museums. In the world of zoos, in addition to its recreational functions may perform the functions of environmental education, upbringing respect for the environment and work as a research enterprise. While in the eyes of Perm , the zoo is a certain image object for the city, raising its status compared to other cities , that is, the city is a means of identification.

Territory of Esplanade ranks second in the ranking of the most talked about change. In 1960 - 70s during the active development of the city it was cleared the space housing construction, but the project of one of the Perm architects was transformed it into a large open space in conjunction with surround buildings form a single plan's composition. Three quarters converted to esplanade become the hallmark of Perm.

In comparison with the territory Chernyayevsky forest it caused much less excitement. Its opinion on the proposal expressed 220 people (14.3 % of all references), including 70% of them argued for the preservation of recreational functions esplanade share against 27 % of residents are in favor of a change in its use.

Most of the arguments for retaining the existing use (about 40% of the total) are based on the perception of the Esplanade as a recreational facility - the venue of the city's celebrations and festivals. The addresses residents say the probability of loss of these functions, due to changes in land use. The townspeople called Esplanade «The only place where you can relax with children ", 'place of favorite holidays." A group of residents insists on maintaining the Esplanade as a cultural heritage site. Thus, most people like to characterize the Esplanade important to identify their city, refers to her as a symbol of Perm.

In the public mind Esplanade residents perceived as an integral part of the city and its culture, as opposed to other provincial cities as "highlight" of Perm. At this point explanations used residents: "We can lose shape Perm", "This is the center of the city, its 'face', which is necessary to make beautiful", "Pride, heritage Perm" and others.

The arguments supporting the position of the applicant for change of use, based on perceptions of underground space development of the Esplanade as "a step forward for the city" and high-tech image project, which will raise the status of the city. As an example, speech: «Underground Mall - it's not bad. Breathes new technologies». This argument, like the previous one, reveals the need for citizens to identify, illustrates the importance of assessing hometown side. Hypothesis is supported by the statements of individual residents of the need for other unconditional attributes of "success" of Russian cities "indigenous Permiaks just dream about Metro and the water park." However, the nature of the change - placing the mall in these appeals is blurred for appeal of the idea.

All most discussed objects - zoo hosted part of the territory Chernyayevsky Forest and Esplanade - the elements forming urban identity. Identification processes underlie the formation of relatively stable social interests, that is, lead to the formation of the local community. [1] With the help of these urban characters formed stable mental communication within the urban community - a sense of community with the territory, a sense of "city".

For positive identification of members of the urban community is important, whether the territory develops and how it is evaluated by other [2]. In particular, the existence in the city zoo "European level", which is mentioned in a variety of applications, is a means of external identification, the identification associated with the estimation of the city outside.

Obviously, uniform, monolithic "urban identity" is not possible, since different social groups have their own, differing in type and content, views about the city, its values and interests in the citywide resources [3], such as, for example, an area of forest or small river valley.

The analysis revealed various appeals of citizen's awareness and mindfulness in making decisions and formulating their own opinions on Urban Affairs and the difference in the degree of readiness of citizens to take responsibility for their decision.

Some residents of the city characterized by the ability to perceive complex, consider several interdependent factors - is traced in the analysis-cited arguments. The situation unfolding around changing land use of urban forests and valleys of small rivers, allows you to select a group of people, differing development of environmental thinking, guided when deciding the principles of sustainable development.

Nevertheless, most residents look at the city's problems unilaterally, often expressed intuitively guided or conventional notions of "modern" city with multilevel underground shops, "European" zoo on site urban forests and high-rise buildings in the valley of the small river.

In a community that when making the choice based on the generally accepted ideas, simplifies the process of manipulating opinion using the media and invited experts. These technologies have been applied in the recent hearings on draft amendments to the General Plan. Feedbacks when we analyze complaints of residents in the administration of the city of Perm, research on this issue will continue.

An analysis of the complaints of residents concluded that public hearings could be an effective tool for strategic decision-making, only in the case of a conscious attitude to the future residents of the city, as well as if they have a comprehensive knowledge of urban development relating to legal, economic, political and social processes.

Under these conditions, of particular importance in the task of forming citizens citizenship and the creation of public institutions that act as intermediaries between citizens and the government, the business community. However, despite the active work of public organizations of Perm, some citizens in the appeals expressed dissatisfaction with such organizations. This indicates a lack of representation of the interests of the residents of the city by public organizations or distorted perception of the position of public men.

Conducted public hearings showed that neither residents nor the government nor the business community was not ready to discuss together solutions. Residents were not sufficiently educated in urban planning and put yourself at risk of manipulation by other party's debate. The administration has been unable to provide the necessary conditions for effective discussion of projects and businessmen do not want to look into the eyes of their customers.

Educating residents conscious attitude toward the city can be stimulated from above - by providing the most comfortable environment discuss urban projects (and informative handouts available, exposition materials, equal opportunity to speak to all participants of the discussion) , or through the creation of alternative possibilities for participation of residents : preliminary public discussion on the draft , Civilian expertise, project seminars, surveys and more.

The experience of countries that use mechanisms for involving the urban community in planning for a long time, shows that the change in terms of the debate in making strategic decisions in the direction of the interests of all stakeholders benefit all [4]: power - in enhancing its legitimacy and credibility with citizens, residents - in consideration of their needs and desires and the business community - to identify the interests of consumers.

Unidade Residencial da Reboleira Sul. Critical reading of the “Optimist Suburbia” that Sá Rico designed and J. Pimenta built in the Lisbon suburb

Bruno Macedo Ferreira

Abstract. *This communication aims to present part of an investigation that, by surveying 30 cases study unpublished sought to understand the phenomenon of residential occupation of the northern suburb of Lisbon. Questions whether the evolution of the territory built in the suburbs (architectural and urban planning) when, in the late 1960s, the ideals of neoliberalism, the emergence of large property developers and a large demographic pressure reshape the process of urban growth and the logic of metropolitan relations (the traditional building lot to lot by the production of large urban packages) and urban area in the suburbs of Lisbon acquires its contemporary shape. The suburban growth recorded in Amadora is the most emblematic expression of the suburbanization process from 1950s reconfigured the territory of the Lisbon Metropolitan Area. Specifically we intend to present the Urbanização da Reboleira for being a "pioneer" and paradigmatic case. These large residential construction packages ex-novo found in Modern tabula rasa and its social optimism a model of easy operability. Designed by architects trained in the values of Modernity, this also enables us to identify the time when the Portuguese architects were losing capacity to intervene, from primary responsibility for the design of the territory (up to 50s) to figure technicians ensured that only approval of real estate projects. The Urbanização da Reboleira Sul is an initiative of a group of small landowners and their masterplan is the responsibility of the architect Sá Rico. Once approved the masterplan, the construction process proceeds to the liability of J. Pimenta (then the largest real estate developer and builder in the country) who, with the connivance of local government, adulterous urban principles originally defined. This was a usual strategy of this promoter - clearly speculative process that obeyed only to the logic of the market.*

Key Words: *J. Pimenta, Lisbon Metropolitan Area, real estate developers, suburb; Urbanização da Reboleira Sul.*

The formation of an urban Amadora. Amadora Masterplan

Urban growth recorded in Amadora is the most emblematic expression of the suburbanization process from late 1950 restructures the entire logic of metropolitan relationships. These territories that until that time were dominated by an agricultural landscape punctuated by small urbanized centers, a lapse of 20 years, gave rise to extensive densely built-up urban networks by mostly residential buildings (Figure 1).

The beginning of 1950 marks the beginning of the general awareness of the need of urban planning instruments that covered much of the urban territory. It is according to this new consciousness that in 1949 the *Ministério das Obras Públicas (MOP)* is the first to approve a planning public source for Amadora designed by Faria da Costa.

This Plan is intended to consistently organizing the process of urban growth in Amadora, following the logic of building lot by lot (yield buildings with four floors) that had been practicing in Amadora, typology which also came to be practiced by "official" program *Habitacões de Renda Económica*. Following an urban structure based on the street, in the square and the block, set up the main road traces, areas of expansion and the number of floors of the buildings to be constructed in conjunction with the existing urban fabric.

In March 1958, presents a second Amadora Masterplan designed by architect João António de Aguiar (Figure 2). This Plan establishes the scheme circulations of all Amadora, determine

the main roads connecting the village center and links this to the city of Lisbon. It also made a comprehensive zoning scheme which establishes the main uses for each territorial unit and especially sets up housing densities allowed in each. There was also concern Amadora endow a certain autonomy in relation to Lisbon, so set up the profiles of the necessary equipment to which that territory was autonomous in terms of housing, job/industry and equipment. (Nunes, 2011, pp.195)

Figure 1. Aerial photograph of Urbanização da Reboleira, 2013.

João P. Silva Nunes (2011, pp.196) cites a diagnosis made by the team that participated in the studies of *PDM Amadora* summarizing an exemplary way the application of the plan.

“The Aguiar plan was followed in the areas of immediate expansion of existing settlements (Amadora, Damaia, Buraca) (...) (but) now with respect to large areas of urban sprawl of the '70s and '80s, Aguiar Plan is abandoned and replaced isolated projects by the private sector who shall be assessed and approved on the basis of general criteria of the Lisbon Regional Master Plan meanwhile completed (1964). Based on these general criteria and sample approval of proposed subdivision, centers on the Direcção Geral de Planeamento Urbanístico, alter morphologies, types, uses and densities of previous plans”. (CMA, 1990, pp.168-9)

This analysis allows us to trace well the three stages of growth that characterized the construction of the Amadora urban fabric: 1) phase of homes for either housing or homes that were ordered individually builders; 2) phase of buildings yield four floors promoted by “*potos bravos*”; 3) phase of large urban and real estate transactions for private promotion in a short time, once transformed agricultural farms in residential housing developments.

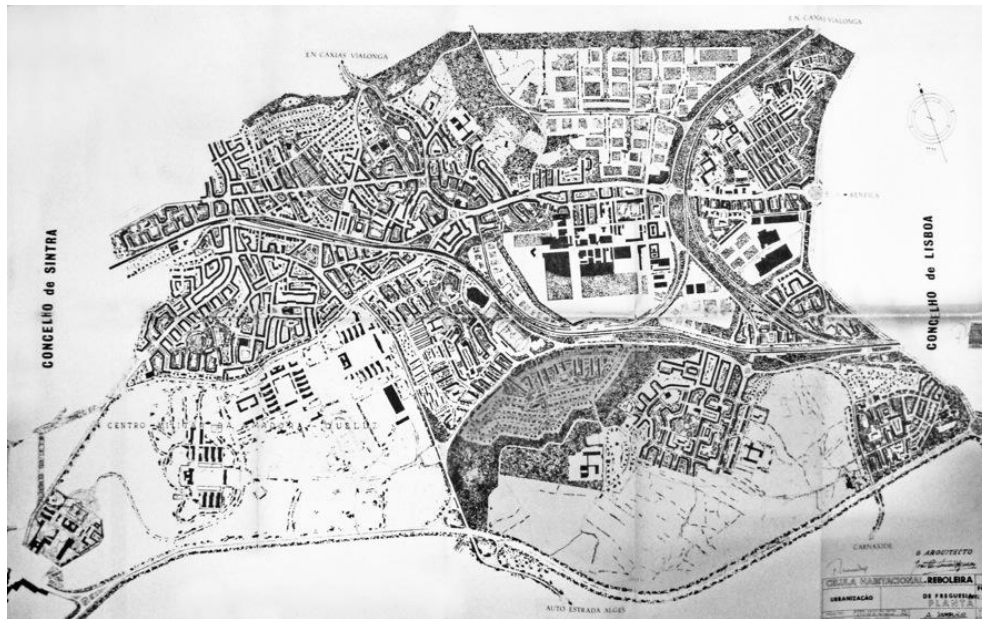

Figure 2. Amadora Masterplan, Architect João Aguiar, 1958.

Reboleira Norte

In late 1950, two private developers, Rodrigo Barbosa Araújo Leite da Silva and Amadeu Cotrim Garcez acquired an extensive farm located in *Casal Brandão* ou *Casal da Reboleira*, bounded on the west by the railway line linking Lisbon to Sintra, by *Estrada Militar* south and to the west by the *Quatro Caminhos*.

This location will not have been a fluke, because it allowed benefiting from a series of strongly attractive factors for this type of venture. Enjoyed is the low cost of purchasing agricultural land; benefited from the synergies created by the "front" of urbanization that is recorded in the neighboring land of Benfica, the Buraca and Damaia; the recent (1957) electrification of railway line that allowed substantial technological improvements in the management of the traffic line and consequently the frequency of trains; easy accessibility to the center of Lisbon, either through private road transport either by public transport (train) in less than 10 minutes put the potential residents of central Lisbon.

These promoters wanted there to create a new "garden-city/satellite" of capital seeking to attract a population group to aspire to reside in a suburb evocative of an experience that is associated with the countryside and green spaces to the benefits of urban life and the dynamism that of city services offer.

*"Eight minutes from the capital
is simply herself
built in top condition and a lovely place
here is the satellite city of Reboleira
true garden-city". (O Século, July 4, 1964)*

In December 1959 shall be submitted to the technical services of the Oeiras Municipality design of streets that prosecutors plan to send the couple running in Reboleira land could begin to urbanization in accordance with the Amadora Masterplan (Figure 3). This plan follows the planning assumptions previously set by the architect João António de Aguiar and is one of the leading builders *EMUR – Empresa de Urbanismo e Construções Lda*.

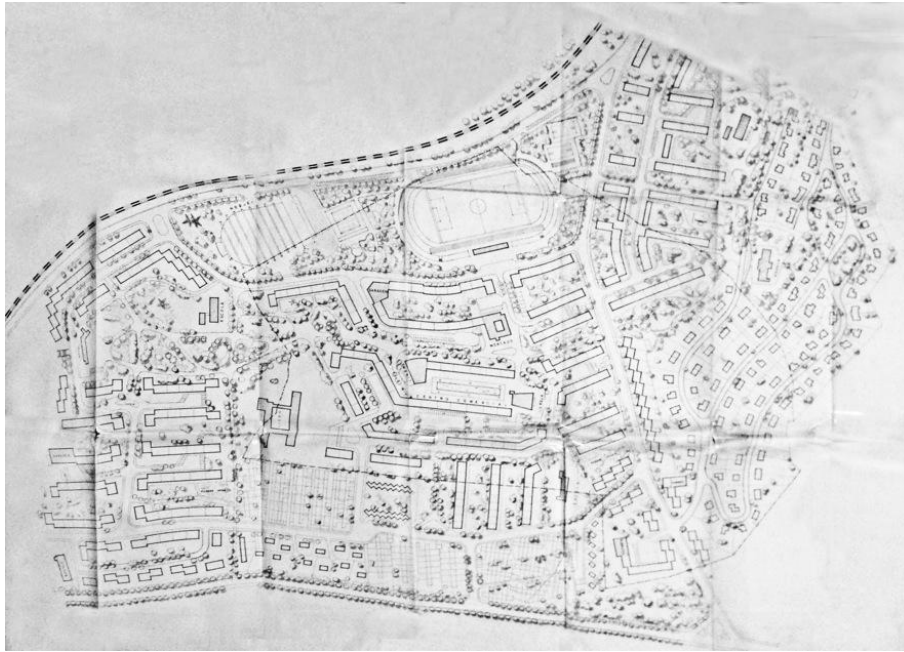

Figure 3. Reboleira Norte Urban Plan, Architect João Aguiar, 1958.

At this time is a celebrated deed transfer of land between the municipality and the promoters. This scripture was to be adjusted several times during the year 1960, and in July 1960 signed the final version of the urbanization contract. Under this contract settled down land that would be assigned to building public facilities (playground, school, college, church, market, sports park with swimming pool, skating rink, basketball and volleyball) in an area of about 50000 m².

The urban principles established in the plan were based on contemporary studies developed internationally in the English garden city. Thus the center of the housing development was planned location of buildings with height between six and eight stories, with the ground floor was planned location of trade. The remaining buildings would be organized in band housing buildings with four floors. On the hillside to the south, across the main boulevard linking the *Quatro Caminhos* (current Av. D. José I) was provided for the construction of about 250 houses. The set was completed by an inn and a car garage.

"There was concern the Reboleira buildings obey a design that does not hurt the entrenched traditions preferences and therefore did not have style too bold, but not ceased to be modern and attractive lines." (Diário Popular, June 1, 1963)

In about 24 hectares was envisaged that a population that was around 140 inhabitants/hectares had been established as the Amadora Masterplan.

"The Reboleira will be a residential unit and not a neighborhood. Will satisfy the needs of its people with their own resources (...) In Reboleira is to take the effect of making an urban plan that's best interest and can integrate into the spirit of a satellite city. Is noteworthy, however, that Reboleira will become self-sufficient urban center. (...) [According to the general plan] have all the requirements of the most modern urban centers, the characteristics of order, cleanliness, convenience and taste indispensable to the existence of population centers in the civilized world. The Reboleira will not shy but authentic "lungs" of vegetation gardens. A vast park and many garden areas provide a healthy life". (O Século, July 4, 1964)

In urbanization contract was also established that the plots assigned and for the construction of buildings of public interest ground, could not be given another use, but they would return to the immediate possession of the original owners. The Municipality was also in charge of endeavor, to the extent that it is possible for the brevity of construction of such establishments.

Was initially scheduled starting date of construction that established the late 1962 and early 1964 as the deadline for the construction of the facilities. However many of the efforts of the promoters were not met and shortages experienced by populations made him feel. The Municipality was justified that some of this facilities to Municipality relied on foreign entities and therefore could do little. However, it is reported the construction of a Police station on land previously intended for movie theater, preventing future construction of this, and the construction of a playground outside the ceded plot for this purpose.

In August 1965 the construction of the Reboleira railway station was embargoed by works are being carried out, for access to the station, which collided with a *Aqueduto das Águas Livres*, as well as the sewerage system. In a letter of June 1966, CP advises homeowners to operational the way station was not considered a priority issue because it could only come into operation while the new Santa Cruz station, and saw no urgency in solving this problem the much demanded by residents.

In August 1967 a large part of the streets, public parks and green spaces of trees were already completed.

With all already "customary" adventures in this type of processes that extend over a long period of time, the work planned on the southern slopes were not proceeding as designed, and it is thus that in 1966, require the approval of the Oeiras Municipality of Reboleira Sul Urban Plan.

Reboleira Sul Urban Plan

The Reboleira Sul Urban Plan marks a new cycle in the process of urbanization in the Amadora. These lands were given to a large number of owners and were given responsibility for building, among others, *Empreendimento Urbanos e Turismo J. Pimenta, SARL*, at the time the most important real estate developer to work in Lisbon Metropolitan Area (LMA).

Fernando Canêças de Moraes, owner of land in the Reboleira south zone, whose review was provided for the MOP in November 1964, presented in May 1966 the study of urbanization the responsibility of the architect Antonio Sarrico Santos (Sá Rico) (Figure 4).

Figure 4. Model Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

The Reboleira Sul Urban Plan follows the experience that the architect Sá Rico had experienced in 1963 Buraca Urban Plan. Although recalling that this plan, this has been the plan of Buraca followed the previous assumptions expressed in the urban lan of the Amadora designed by architect João Aguiar, the author stresses that "*this work is in relation to the Buraca*

a breakthrough. All the space from the exterior to the interior has been carefully considered and studied". (Sá Rico, 1966, pp.5)

In the previous plan was expected to Reboleira a density of 141 inhabitants/hectare, corresponding to a ground occupation divided into three functions: about 1/3 of the area was intended for four-story buildings, one third the houses and the rest as green zone. This new plan was reviewing all this data, and the cell with about 39 hectares provided an occupational density of around 157 inhabitants/hectare, which corresponded to 1923 dwellings in tenement buildings and 103 townhouses, for an estimated population of 6078 people.

This urban plan was prepared over and over and its descriptive memory is an exhaustive document that deserves emphasis here. This text about urbanism and general considerations about the topics of discussion at the time, characterizes the whole of difficulty representing the production of a plan of this scale in the Portuguese context in the 1960s. Objectively explains each option taken, always based on comparison with other proposals "official" promoted by the regime (Olivais Norte, Olivais Sul and Chelas) and other contemporary international experiences in vogue (in particular the experiences of British new towns).

Buraca essay

"This work follows as urban study certain amplitude of the Buraca officially approved approximately two years ago by MOP and currently running, and experience which necessarily benefit.

Although considered a correct solution for all those who are linked to the problems of urbanism is about me outdated, not only in its general conception of organizing spaces, as in the work processes adopted. There are aspects that I consider negative and that its development in detail accentuated. Too bad though it had been a very low level of collaboration in the implementation of the road and sewage project that very committed and the solution led to a review of final settlement, but have committed certain aspects of the initial solution.

Among the many negative aspects of this work, whose attribute blame myself, regard as key:

I have limited, due to commitments made by the official plan, the definition of outer space and the study of their organization, starting from the abstract definition imposed on that plan, determined lot sizing.

This necessarily led me to a disintegration of human space by solving the truncated, only one of its aspects, which will lead implicitly to an adulteration of the final development of the scale of the lot.

The lack of an initial synchronization, due to an in-depth study, could lead to the disintegration of the space itself, been further accentuate all negative positions.

Were all these negative aspects, the result of my previous experience I deleted the job that I now present [Reboleira Sul], a consequence of a much more in-depth study that led to the search for a comprehensive solution and the proposal which I now present, and that is a remarkable advance in respect of that work". (Sá Rico, 1966, pp.19-20).

This excerpt is particularly important because it demonstrates quite clearly awareness that architects participating in the construction of the Lisbon suburb had on their achievements. Allows us to refute many preconceived ideas that these authors considered as "minor" only guided by the profit motive inherent in real estate.

Urban and populational reality of Reboleira Norte

To start the urban plan, architect Sá Rico calls attention to the lack of a sociological study able to characterize the Amadora territory with a rigor/depth that allows making architectural choices based on that diagnosis.

Reference is made to the survey conducted in 1960 under the responsibility of the architect João Aguiar when the Amadora Masterplan, which, though done with some care, rested on bases considered, outdated when the population forecast provided for each dwelling. This simplicity of position and the lack of a greater depth of study and objectivity of the plan were stated as the cause for the uncontrolled number of dwelling that were occurring in the execution in the north. Thus Sá Rico lies on the task to conduct a survey to the situation in Reboleira Norte in order to gather data for designing a system based on real facts and not on outdated estimates urban plan.

"From the survey it was possible to do that and the northern part of Reboleira ever built and which represents one third of the whole area, I concluded:

- over 1413 dwellings in 1002 provided the official plan were executed.*
- this represents an increase of 411 dwellings which corresponds, according to the same plan, a population increase of the order of 1233 people.*
- beyond that increasing the number of dwellings, there to consider further 62 stores, 6 offices, 26 garages, 10 warehouses, storerooms 7 and a small factory.*
- assistance of worship is taken through a Protestant church in a working area for a shop.*
- buildings set in the plan with greater height, 7 floors, were built with 8 floors.*
- the buildings are built higher floors and 10 were included in the plan with only 5 floors.*
- a building with four plots that corresponded to the plane 32 dwellings were built five lots and there was an overall increase of 30 dwellings.*

In addition to the checks made on the built and part of which is only one third of the whole area, I am aware of some studies and projects approved with 261 dwellings for 85 provided in the official plan, which gives a further increase of 176 dwellings and therefore more 428 people.

From here I can only conclude that for the northern area of Reboleira, with a part already built and running another shall be given, according to the data plan a population increase of the order of 2,000 people". (Sá Rico, 1966, pp.38-40)

General Structure of the Proposal

The first projective plan options passed by the restructuring of the connections to the surrounding areas. With this reformulation, we sought to better integrate this cell housing in major regional roads in the AML and the large circular Lisbon, which quickly lead residents to the city of Lisbon. In terms of structuring the proposal is clearly highlighted the importance of the train station, while iron pole generator centrality of whole cell (Figure 5).

"Due to the two movements that create a daily flow of people, with greater strength at peak times, one in the morning and another in the late afternoon in the opposite direction. These two movements create lines necessarily constraints of the physical strength of the cell. This led me to consider the season the dominant axis of the whole composition, thus seeking to give physical expression to a strong human condition". (Sá Rico, 1966, pp.24)

Thus, the movement of pedestrians lines were drawn, with different expressions according to their flow from the attraction pole of station. In the vicinity of the fundamental elements vitalization of cell were found, *"according to a structure that almost reminds the correct form of a large tree trunk, its branches more or less long, to unfold in other smaller coming out of it"* (Sá Rico, 1966, pp.24). *On the hill opposite the station and the culmination of the largest power line was proposed location of the large shopping center.*

The overall composition of the cell is affected by this central shaft which are derived from two orthogonal axes that determine the whole composition of the cell and from which all external spaces are shaped. Sá Rico states that *"this sense of composition is what best suits the natural development of the land, and in it we find a quite space organization that comes close to our traditional area of strong Mediterranean incidences". (Sá Rico, 1966, pp.25).*

Figure 5. Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

Every cell development, following this axis follows the natural development of land extending in gentle upward slope from the station, watching the *Estrada Militar* to the *Quatro Caminhos*. Hence the composition of orthogonal blocks that will progressively combining altimetry oscillation creating several spaces.

"Just so, a certain physical space can give strength to a human space that corresponds to it and in which man can find that scale of values which lead him to identify it with you and appropriates it, then feeling sir what to it was created. Only then urbanism identifies with the architecture and from there all his abstract sense became reality, serving the purpose it is intended, man". (Sá Rico, 1966, pp. 26-7)

The human cell center

Sá Rico stresses that the human element was considered in structuring the plan and organization of spaces, *"all his strength"*. Its strong presence is evidenced by not opting for a large civic and commercial center located in a single point. Choose to organize and conveniently treat a number of walking routes that they would play the role of "canal space" public and civic experience (Figure 6).

Figure 6. Scheme of the Human Center of Reboleira Sul, Architect Sá Rico, 1966.

Classified in the general line composition, the center extends along the central part of the cell following a orthogonal composition. It extends almost from the movie theater (way station train) to the area of housing, including the two major shopping centers and rises orthogonally to the church. Around it, integrating it, gravitate fundamental elements aimed at equipping children: two primary schools; the kindergarten; two playgrounds; and the medical center. Then the pawn, with special emphasis on the child can move "freely and wildly". The car gives access to it from all sides, without the trespass.

Circulation

"It has such force the presence of the car in urban space that cannot be forgotten in structuring any neighborhood. Must be equated directly linked to the man with which it forms a binomial, the better or worse resolution of which results in a better or worse urban solution. (...)

The binomial vehicle-pedestrian was here equated forming a system of two equations each of which corresponds to a scale so that both, in their own space if you continue and complete without counter". (Sá Rico, 1966, pp.27-8)

As already experienced in the Buraca Urban Plan, also in Reboleira Sul, entire road system of the cell was chalked within an integrated overall scheme considering four different types of roads, the V1, V2, V3 and V4, designations adopted by Le Corbusier in its rule of 7V (Figure 7).

Figure 7. Road Structure of Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

Although taking a different scale and dimensions, we adopted the same principle: V1 - Freeway, via extensive regional traffic flow and speed of exclusive use for mechanical transit; V2 - roads intercellular distribution of housing unit, are responsible for channeling all the different mechanical cells for V1 transit. Make the connection between the cells and the common center of the unit, having no direct contact with the housing; V3 - roads penetration and mechanical movement of each cell. Completely individualized pathways for pedestrians give direct access to these dwellings and through parking areas. Also be avoided crossing of the paths of pedestrians in the main points intersect at different levels, by "bridging" or tunnels; V4 - roads and paths for pedestrians only.

"By analyzing the urban structure of the cell, easily verifies that the pedestrian was given such presence that almost all the solution evolves from the power lines down by it.

Leaving the station, core of the entire drive at peak times, to the most distant zone, along the four paths, a series of platforms serving a regular route. They have however increased expression, which corresponds to a larger footprint at the point of gravity of the cell, those who track the movement towards the station represents the largest movement within". (Sá Rico, 1966, pp.29)

The issue of parking was also equated with the fundamental structure of the residential unit. It was thus destined for an area of 21070 m² open and parked in an underground area of 3998 m².

"Although it has not been able to achieve optimal prediction of 1 car per house, that they need to check only come among us many years from now, however could exceed the averages of many European countries, where the rate of cars per capita exceeds our". (Sá Rico, 1966, pp.35)

Three large garages at key points, such as run a gas station were also provided. *"The individual garages were not considered here, for fear that given the structure of the cell, were transformed into small workshops, improper appearance"*. (Sá Rico, 1966, pp.57)

Facilities

Sá Rico, warning that the items of facilities referred to in the Amadora Masterplan was meager that claimed many changes during the implementation of the plans. It was said that the situation should be changed as part of a broad-based review of the entire Urban Plan revision that was considered urgent and which had been requested by *Conselho Superior de Obras Públicas*.

"As I mentioned in the Buraca Urban Plan of our sociology studies are poor or virtually non-existent, which further aggravates the problem.

However, we cannot sit back and imposes the programming for the whole cell from a ware able to give you the self-sufficiency of its scale. (...)

For the human mass that forms our neighborhoods is quite heterogeneous, economically weak, socially poorly structured, very far from saturation of their human potential, behaves in a disorderly and unpredictable prey to the harmful effects of the recent past of disabled proper conditions, which correspond to conditions of habitability also disabled. (...)

If we are only just beginning, for reasons of natural social evolution, to look seriously for the housing problem, without a basic structure that still meets, no wonder that only several years from now, after the experience of some valid constructions , begin to have some elements capable of providing us with the data necessary for the establishment of certain facilities programs. (...)

That does not prevent me however that, based on the data and information within my reach at this time, in consultation with foreign counterparts accomplishments, in direct observation of certain behavior of populations, establish a program of urban equipping of certain scale". (Sá Rico, 1966, pp.42-4)

Thus, considering the assumed population and scale of the plan, several devices have been provided in order to make the cell self-sufficient in their primary needs.

Although the absence of a pre-primary education official in Portugal, two kindergartens were provided. With regard to primary schools, has mentioned the experiences of English new town where was considered the primary school as the starting point for structuring the city itself. Thus, it was based on the route of the child that the cell was scaled. Were therefore envisaged two primary schools located in the center of gravity of the metric and human cell. Each school would be well served by the network paths due to the mechanical individualized pedestrian traffic.

The level of health care services were provided to local own medical center, in buildings of differentiated for housing, located in a central area that is served by car access and privileged pedestrian access.

It was also provided the location for a church, the possibility to install a movie theater at one end of the cell, located along a route of intercellular transit and railway line, thus benefiting from the possibility of attracting public outside the cell.

Trade

In the study conducted for the resolution of commercial program experiences that were being made in several English New Towns and Olivais Sul and given the characteristics of the cell, the topographic development at pedestrian pathways and their structure were observed were considered four commercial centers: A great center opposite the station, which cumulatively play the role of civic center; another which proposed a new model in which the function normally performed by a market were replaced by a supermarket that worked the most hours according to the life of the inhabitants. *"This whole cell mode, despite its fusiform configuration*

would be covered by a commercial ware that does not oblige a housewife for your needs day-to-day, long distances". (Sá Rico, 1966, pp.51-2)

Green Spaces

At the top of the slope, and corresponding to the zone of protection of the *Estrada Militar* will develop, under the proper afforestation plan, a dense wooded area that will frame the new neighborhood (Figure 8).

Figure 8. Green Spaces of Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

"Perfect green line separating the living from the white buildings and bright blue Lisbon sky.

From there, cascading, born various branches of trees, through the villas that bathing the linear center in order to give greater strength and comfort to footpaths and some free, spaces corresponding to the schools the most powerful, the kindergartener, the playground, end up coming faintly die against the strong and dense area of trees that must be born after the train line to protect the natural noise of the trains". (Sá Rico, 1966, pp.54-5)

Sá Rico proposes that all open spaces, the permeable zones and afforestation are the subject of a timely landscaped study, consciously prepared by a landscape architect. These zones would be designed so seamlessly with playgrounds considered "indispensable in any neighborhood." Recreational areas for teens and older were also thought in relation to green spaces.

Regarding games area, was considered a games area-wide cell, regardless of considering the games area designed for the Reboleira Norte, but is separated from it by a cell via high flow of traffic. Thus a basketball and roller hockey, a tennis court, a swimming pool with attached and integrated them an assembly center buildings and a clubhouse was planned.

Home Organization

The time of presentation of the Urban Plan, also pointing-three housing typologies combined in various ways, would serve the residential function of the whole. Regarding home T2 to T4 were provided (Figure 9).

Figure 9. Plans of housing typologies of Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

“The internal organization of the home must be considered a program that satisfies certain human requests. And for completing it must sit on certain data that clarify the sociology of mass human behavior that will serve.

Whereas this cell to home an internal program to serve a population of already evolved middle class or continuous evolution, it was structured and organized, taking into account all the above principles.

Thus, a single dialog, speak the whole neighborhood”. (Sá Rico, 1966, pp.37) (Figure10)

Figure 10. Photograph of the model of a housing block of Reboleira Sul Urban Plan, Architect Sá Rico, 1966.

Approval process and review of the Urban Plan

In May 1968 the review of the Reboleira Sul Urban Plan, designed to give satisfaction to the comments made by the various entities involved in the approval of the Urban Plan was presented at the Oeiras Municipality (Figure11).

Figure 11. Review of Reboleira Sul Urban Plan, Architect Sá Rico, 1968.

Imposed changes were related to the need for improvement of the road system, for improved handling and mechanical irrigation transit through the entire cell trying yet not completely penetrate the core. Thus pedestrian crossings are reduced uneven leading to obvious economic benefits, as well as pedestrian pathways are reduced. Also makes repairs to the street level design, including the requirement walks the streets of most car traffic and were eliminated the underground car parks, distributing them to the surface without increasing the area for parking. It has also increased the area of the central green area to constitute a true lung plan and revised the height of volumes, proceeding to the standardization aiming to make the most economical running.

In April 1971 it signed the final contract for the donation of land between the city and the owners of the land where the following final values are established: Total area 38.75 hectares; 6078 inhabitants; 1923 block houses; 103 homes; population density of 156.8 inhabitants/hectare.

Implementation of the Plan and construction of buildings

Shortly after adoption of the Urban Plan, begins the work of earthworks for the construction of buildings. The construction process is then controlled by the *Empreendimento Urbanos e Turismo J. Pimenta, SARL* the meantime had acquired some parcels of land to the original landowners and developers of Urban Plan.

From that moment begins a new process that will lead to many changes were clearly misrepresenting the approved plans. As had already happened in the Reboleira Norte, this company starts a speculative process clearly about lots already approved.

In 1970 are subject to the approval of the project for residential buildings designed by the architect Sa Rico and would be built by *SUIÇOPOR – Imobiliária Suíço Portuguesa Lda*. In these projects the housing typologies previously presented as small simplifications to the interior design of the homes were observed.

For the same year, the responsibility of *J. Pimenta*, a change in some portions is required. With the pretext of pursuing some adjustments in retaining walls and track alignment (resulting from the work of moves land) intended to increase the number of parking spaces. It is also intended to extend the zone of construction through the implementation of eight new lots, and

seven of the lots already approved, increasing the number of floors. As justification was advanced the need for reimbursement from increased expenditure generated by the arrangement of the soil and the various works of rectification. This request would be accepted by the council and was the "first stone" to the process that would follow.

In terms of the types of buildings, tabula rasa on the work of the architect Sa Rico was taken. The types T2, T3 and T4 proposals were replaced by T0 and T1 types, offering only the regulatory minimum areas required for a bedroom, living room and a kitchenette. Thus T0 apartments include a bathroom, living-room and kitchenette and T1 presented bedroom, bathroom, living-room and kitchenette. These properties were offered for sale and rent already furnished. In the room was provided a bed, bedside tables and wardrobe; in-room room was included a sofa bed, a bench and coffee table, dining table with four chairs, a cabinet with storage shelf and two lamps; the kitchenette was installed a stove, water heater and countertop sinks.

The justification for this change typologies was repeated throughout the various change orders:

"In general, the buildings set in the plan intended to dwellings of a kind apartment of one or two divisions, systems that has proven model in solving the housing problem in the area concerned". (Sá Rico, 1966)

This process was being followed by the same promoter company in the Espargal neighborhood in Paço de Arcos (Ferreira, 2010, pp.156-60). The request for change of type was joined often changes the configuration of buildings, number of floors and occupation of the ground floor with trade by claiming that the configuration previously approved (as in buildings already done) *"caused poor conditions of insolation, rectification and visual relief"* (Silva, 1969). This strategy obviously configured a market strategy development company, because with these types T0 and T1 could be an increase in population density with natural economic benefits (Figure12).

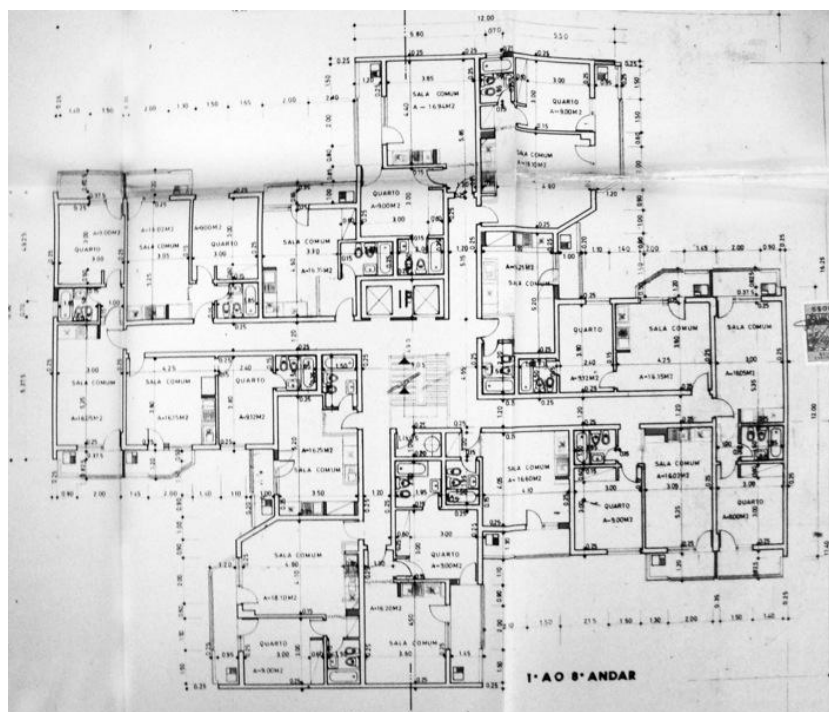

Figure 12. Type plan of cross buildings promoted by J. Pimenta, Architect Hélder Silva, 1971.

Final considerations

This text is not intended to present a critical reading of the urban and architectural options adopted by the various stakeholders designers throughout the construction process of urbanization of the territory of Reboleira Sul. It is rather a first survey that subsequently compared with other cases study, will be the subject of this critical view that will surely be useful to extract more fruitful conclusions.

Thus made a first survey of facts which will then be subject to analysis and framework regarding the responsibilities of both parties - developers, architects, builders and authority. This is also the first basis for understanding the transformations and the type of ownership that the suffering was built over these 40 years.

Future will be framed commercial strategy construction company J. Pimenta whom great responsibility can be assigned in the construction of urban-metropolitan territory of the LMA, as can be easily proved with the construction of Urbanização da Reboleira in Amadora, Espargal neighborhood in Paço de Arcos and the Pampilheira neighborhood in Cascais among others, as well as in the city of Porto. The commercial strategy and market logic of this company has been the subject of study (Nunes, 2011), as well as strong advertising campaign that was promoted at the time of construction in various media. This study also highlights the notoriety that its founder João Pimenta was acquired over the decades of 1960-80 in the social structure in Amadora.

We can conclude with a journalistic piece "*Reboleira: the landscaped gardens to the monumental disappointment*", which illustrates the transformation that occurred in this area over 20 years - a garden city to a "forest of reinforced concrete"

"The city Reboleira it really is more concrete, dehumanized buildings where many, many floors are honeycombs of human hives where people are stowed coo cheap merchandise, uninteresting. The law of money, and fast income overlap with the values of the man-man. Instead of the promised gardens and socializing, sites where mercandaja love easy. Because Reboleira (...) has become a true "cashbah" where every corner and through the night it sells and buys love and no requests for debasing vices. In easy but well enroupada of sound "nightclubs" where prostitution is practiced widely and suggested coverage. Given this (and more) ... We can only ask - which houses the original draft Reboleira, "Garden City"? How could so radically change". (O Século, January 28, 1975)

Tenure of urban land: structure, form and transformation of the original urban space of the city of Ribeirão Preto - Sp, Brazil

Dirceu Piccinato Junior, Ivone Salgado

University of Campinas; Rodovia D. Pedro I, Km 136, Jardim Santa Cândida, 13020-904, Campinas – SP, Brazil. E-mail: piccinato.jr@gmail.com_salgadoivone@uol.com.br.

Abstract. *The purpose of this paper is to discuss the urban morphological aspects of cities governed by the juridical regime of the emphyteusis, recurrent situation in northeastern São Paulo state - Brazil, with special attention to the city of Ribeirão Preto. The land concession to the Catholic Church was recurrent in Brazil during the colonial and imperial periods for the foundation of cities. As these lands were destined to the formation of patrimonial goods of a devotion saint of the residents, they couldn't be commercialized. The tenure reveals a relation in which there is an owner - landlord - who has the direct control of the urban land, granting another - leaseholder - the useful domain of the land, giving the latter the right to use the land, the obligation of an annual tax payment and a compromise of giving a percentage of the property sale. In 1845 some farmers donated a tract of land for the formation of the land assets of the saint São Sebastião, where is now the city of Ribeirão Preto. This conjuncture defined the structure, the form and the transformations of the original urban space of the city.*

Key Words: tenure or emphyteusis, urban land, Catholic Church, Ribeirão Preto-SP, morphological urban aspects

Introduction

The urban space is formed by a social diversity, so every society seeks to reproduce forms, whether permanent or not, on the surface. This means that these forms obey a given sociopolitical order of the group that builds them, functionally responding to a present sociability which also regulates the use of urban space and the resources contained therein, thus defining their own modes of appropriation of the city (Moraes, 2005). Hence, we can consider the full character of a social process in the urban morphology studies.

When our eyes are directed to Brazil, attempting to list the aspects that outlined the urban space of Brazilian cities, the study of urban morphology, according to this methodology, must consider our social, cultural, geographical and historical contexts.

According to Vasconcelos (2009) in the examination of Brazilian cities, their morphology and their aspects, it is possible to identify "modeling agents". These agents have not been jointly present in the urban setting, but when we lean in each case we identify, if not the presence of the majority, at least one, common for all cities. There were five "modeling agents": first, the State, especially in its upper level, ie, the Portuguese Crown, which played a key role in the implantation of the first towns and cities in Brazil. The Portuguese Crown sought to manage its colony from orders sent directly by the Metropolis; second, the Church, which had a role as decisive as the State's one in the structure of the Brazilian cities. The Church in Brazil had been conditioned by the patronage system, in an agreement between the Vatican and the Portuguese Crown. The Church counted on the presence of the Secular Clergy, which was the high hierarchy of the Church (bishops, archbishops, ecclesiastical courts and seminars) and Regular Clergy, formed by religious, male and female orders; third, the Lay Orders, actually Catholic institutions, but relatively independent of the official Church, formed by volunteers of lay men and women; the fourth "agent" is about the economic agents, these agents could be identified as external economic agents, who were landowners, and domestic economic agents, such as traders and financiers, slave traders and craftsmen; finally, the last agent, The Population and Social

Movements, composed by small employees, especially staff, master of letters, surgeons, along with the poor and freed, the slaves (until the year 1888 when slavery was abolished in Brazil) and social movements, the latter extremely important to national history due to the various uprisings, rebellions articulated by dissident social groups.

Urban morphology: some considerations

In recent studies, the understanding of urban morphology presents diverse perspectives of methodological approach; from assessing the physical form of urban spaces, listing as fundamental elements, streets, lots and buildings (Oliveira, 2013); to description and prescription of urban form according to a multidimensional, systematic, exploratory and quantitative environment (Gil, Beirão and Duarte, 2012). Studies of multidisciplinary discussions about urban morphology have made social sciences and humanities studies relevant in the construction of urban space (Whitehand, 2012); in some studies, as developed by Kim (2012) on the urban form of South Korea, we observed a particular attention to the formal aspects of cities and towns having as parameters of analysis the history, as well as the influence of European morphology in the country. A range of different urban forms are examined through a cultural perspective which the construction of the form is the result of theory and practice, describing representations of particular culture and historical conditions (Ehlers, 2011).

These various methodological approaches to urban morphology point us to the fact that the analysis and understanding are configured according to the interdisciplinary relations of science, with different views, as well as specific, economic, cultural and social conditions of a country, a city. In this sense, our work seeks, as well as Ehlers, to discuss the structure, shape and the transformation of the urban space of the city according to social and political articulations in the representation of the physical urban space.

The urban morphological study for us is a cumulative process, every temporal dimension identifies a result and a possibility, a continuous movement. So we pondered that, somehow, every urban formation is also a social formation because the latter necessarily spatializes itself (Moraes, 2005).

The morphological elements are directly related to urban size and can be identified by the form; the analysis of this form requires movement and pathways. Lamas (2010) considers these elements as: the soil, the buildings, the lot (land parcel), the block, the architecture, the layout (the street), the square, among others, "defining and explaining the urban landscape and its structure." (p. 37).

The formation of the religious heritage of Ribeirão Preto

The religious heritage emerged in Brazil in a discrete way, it constituted a tract of land that allowed the construction of the chapel and also the external space recommended by the First Constitutions of the Archbishop of Bahia for the formation of houses to shelter the small *sesmeiros*, giving rise to what would be the future urban core. "On one hand, it occupied a predetermined ground and planted the desired temple; on the other hand, it propitiated the agglomeration of houses and businesses." (Marx, 1991, p. 41).

The territorial plots tended to be large in the progress of the colonization process of Brazil, which hindered the full use of these plots because of high costs and charges. Many of the settlers ended up not having access to land. Those who had the resources could acquire lands, so this large contingent formed by the poorer class ended up forming "clusters" of large landowners.

In the formation of the city of Ribeirão Preto, the researcher Lages (1996, p. 216-217) reports that the religious heritage of the city was dedicated to the Holy Saint São Sebastião and

that the strip of land was donated by many owners over the years 1852, 1853 and 1856 (Table 1).

Table 1. List of donors of land for the constitution of the heritage of São Sebastião of Ribeirão Preto-SP

Donors	Farm	Extension	Date
João Alves da Silva and Ana Delfina Bezerra	Retiro	30 acres	19 Dec, 1952
Severiano João da Silva and Gertrudes Maria Teodora	Retiro	12 acres	16 Mar, 1853
José Borges da Costa and Maria Felizardo	Retiro	9 acres	20 Mar, 1853
Inácio Bruno da Costa and Maria Izidora de Jesus	Retiro	9 acres	19 Apr, 1853
José Borges da Costa and Maria Felizarda	Retiro	12 acres	20 Mar, 1853
José Alves da Silva and Pulcina Maria de Jesus	Barra do Retiro	2 acres	1856

The tracts of land were ceded by one or more landowners so that these disadvantaged workers could settle there. However, the granting of this strip of land did not happen directly to them, the benefited part was always a Catholic saint of devotion, being up to the Church the administrative care of this heritage (Abreu, 2006). In the case of Ribeirão Preto it was possible to identify the boundaries of the religious heritage of the city through the information about the blocks properly listed together with the Archdiocese of Ribeirão Preto and the 1st and 2nd Notary Real Estate Registry (Figure 1).

The management of this heritage was under the care of the Factory of the Church, which constituted an entity formed by the religious and the good men of the town who watched over the goods of the parish, disposing of land donated in urban dates, ceded under the jurisprudence of the institute of long lease or tenure to those interested in residing in the heritage lands (Ghirardello, 2010).

Once constituted the patrimony of the Holy devotion, local people gathered to build the first building, the chapel. This could not be built everywhere, according to the *First Constitutions of the Archbishop of Bahia*, it should be built on a "high and decent place, free from humidity, private homes, and other walls in a distance in which the processions could walk by without impediments (...)." (Vide, 1853, p. 252, our translation). At this time the religious building and the urban status were defined as a chapel.

With the increase in population, the inhabitants of the chapel could ask the Ecclesiastical and Civil Institutions for the elevation of its urban condition to Parish. The elevation from a Chapel to a Parish status would take into account criteria of demographic and economic order, but the political interests ended up prevailing (Derntl 2013).

Feeling strong enough, the Parish could ask the Civil and Religious Powers for the promotion of its category, achieving the status of village, which meant "finally its political autonomy, the status of a municipality." (Marx, 1991, p. 62). In this condition, it was up to the Village the definition of its term, a territorial limit that could contain chapels, parishes and neighborhoods and corresponded to the territory controlled by the city council. It would also be up to the Village the definition of its park, that was referred to as a smaller geographical area, intended to the division into plots willing to integrate the assets of the city council. "This could divide them into "grounds" (lots) and grant them, upon payment of annual pension, to the residents who asked for them to build their homes." (Fonseca, 2011, p. 30).

To the religious heritage, "property" land of the Saint and managed by the Church, was superimposed a new demarcation, the park, public land. A conflict, however, was established between the civil and religious power about land ownership, a situation that was resolved overlapping the civil power to religious power in most Brazilian cities, but in many other the conflict remains until the present day, as it happens in Ribeirão Preto.

Thus, in the composition of the Brazilian urban landscape, religious buildings outlined the structure and perceived the form.

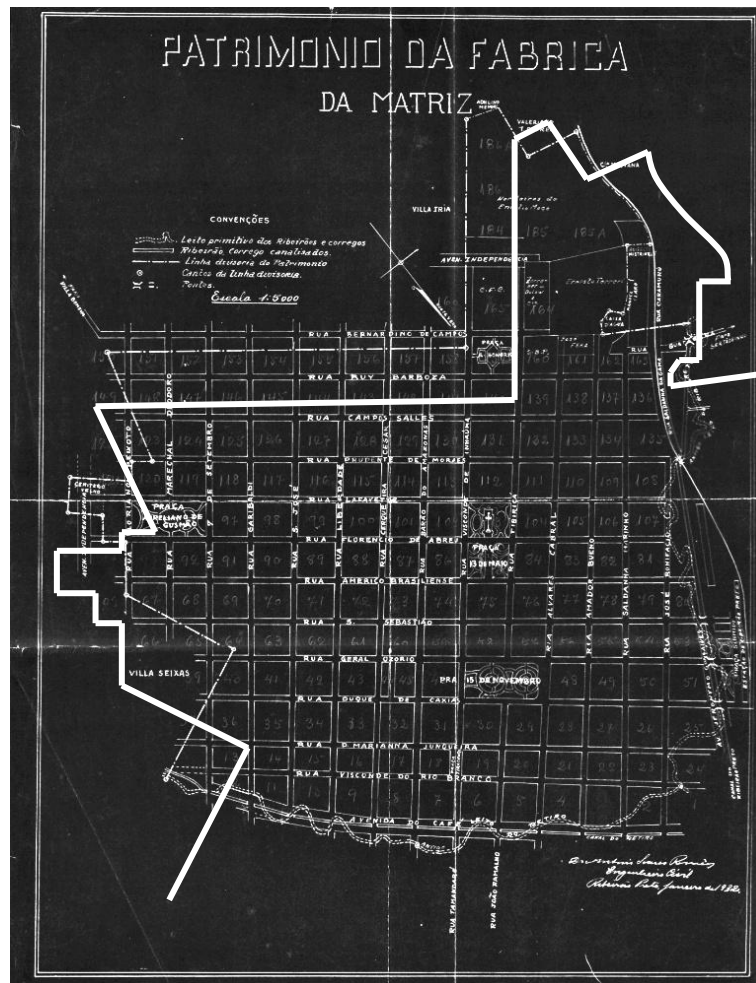

Figure 1. Heritage Factory of the Mother Church of São Sebastião do Ribeirão Preto, 1932. We highlight the limits of the patrimonial lands in the urban space where the city was originated and it is possible to observe the blocks slightly listed (Public Archives and History of Ribeirão Preto).

The presence, poise, refinement and especially the privileged position in which were placed the religious buildings made them ordering agents in the urban space of small and large agglomerations (Marx, 1980).

What is observed is a result of the pragmatism and constructive need that initially demanded simplifying procedures, traces and architecture, however, these principles can be considered as a condition for innovation, transformation of urban space (Teixeira, 2011).

The Institute of Long Lease

The Institute of tenure or long lease of land is a legal instrument formulated in ancient Greece later assimilated into the Roman Empire in order to legitimize the use and retention of workers on the ground. Portugal, during the Middle Age, included this instrument in its set of laws: the first was the Afonsina Ordinances (1500-1514), then the institute was again included in the Manuelina Ordinances (1514-1603) and finally in the Filipina Ordinances (1603-1916), the latter prevailed in Brazilian lands until the year 1916 when it was enacted the first Civil Code which recognized the right of Long Lease. This code remained until 2002, when a new Civil Code was formulated, but little changed about tenure. For this paper, we will take as a source of

analysis the Civil Code of 1916, because it recognizes tenure as a right and because it remained until the beginning of the XXI century. The long lease or tenure is a way to break up the property by a perpetual contract, that is, its holder gives others the powers of use, enjoyment and disposition, only transferring them to third parties with his approval.

The long lease can only occur in uncultivated land or in lands intended for building as the article 680 of the Civil Code points out. One can't therefore establish long lease on the mobile nature goods, or on buildings already constructed or plots already colonized. The long lease's economic purpose is to encourage the use of uncultivated or unbuilt lands.

The institute of tenure or long lease is a territorial alienation contract which divides the ownership of a property into two types of domain: the direct domain (imminent) and indirect domain (useful). This means that there are necessarily two people: the direct landlord who owns the property, and the copyholder that acquires real rights. The first one is the holder of the domain, while the second one has the possession, use and disposal, although subject to certain limitations for the benefit of direct landlord (Monteiro, 1953).

According to Amorim (1986), in Brazil the lands tenured by private personal have as landlord the Church and its religious orders and religious institutions established by them, there is still the imperial family (urban land in the city of Petrópolis-RJ) and some hundreds of individuals in the following percentage: Church, 60% of the tenured lands; 30% are public lands; 3% refers to the former royal family, and the remaining 7% belongs to private individuals.

It is peculiar to the long lease the payment of an annual pension. The value of the pension is a small, symbolic amount and in many cities this tribute was abolished, unlike *Laudêmio*.

The *Laudêmio* is a compensation that has to be paid directly to the landlord for not having exercised the right of purchase option. The obligation to pay the *Laudêmio* is the "seller's" and not the "buyer's". It is important to clarify that in the buying and selling process what is being negotiated is the right of using the land and not the ownership of it.

In Ribeirão Preto, when a resident of heritage lands puts a property on "sale", he will transfer to the new owner only the right to use, because the Church has the ownership of the land. The *Laudêmio* is prepaid, the deed of sale is not tilled and the letter of auction is not issued without having solved the mentioned tribute. The value of *Laudêmio* is 2.5% of the total value.

Ribeirão Preto-SP and its morphological conditions

During the sixteenth, seventeenth, eighteenth and nineteenth centuries, occupying unoccupied and uncultivated lands became a constant attitude among those who wanted to settle, it could be considered, according to Lima (1990) as a "legitimate way of acquiring domain at first, and after in replacing our distorted system of land grants, *sesmarias*" (p. 47). A good escape for these men who had no titles was the foundation of a chapel with a holy of devotion. The grants of land intended to the Church for the establishment of a religious heritage were a way of regularizing the possession of the land.

Under such conjuncture, Lages (1996) and Garcia (2013) agree with the view that the donation of lands to integrate the heritage of São Sebastião do Ribeirão Preto, holy devotion of the locals, was beyond the religious content, that is, these residents had a strategy to legitimize and regularize the land possession.

According to Costa (1955), Lages (1996) and Garcia (2013), there were two attempts of donation to the formation of the heritage that failed, precisely because of the lack of documents proving the legitimacy of the land: the first one happened in 1845 and the second one happened in March 1852. It was only in July 1852 that Ribeirão Preto began to be constituted into the lands of the farms Retiro and Barra do Retiro (Table 1).

Once constituted the patrimony and granted the lands to the formation of the urban space of Ribeirão Preto in lands of São Sebastião, it was essential to nominate a vestryman, who would take care of the patrimonial lands and manage the parish goods. Costa (1955) points out the

figure of Manuel de Nazareth Azevedo, however, Manuel Fernandes do Nascimento, an important figure from the first donations, was the witness and signer of the donors who could not read and write.

According to Garcia (2013), from 1859 on, the responsibility of taking care of the territory, tracing the first streets and building a chapel in honor of the patron saint was entrusted to Manuel Fernandes do Nascimento, however, the researcher points out that there is no document that effectively proves the tracing and the division of lots of the urban territory were actually made by Manuel Fernandes do Nascimento.

Costa (1955), Laureano (1973) and Lages (1996) inform us that even before the final regularization of the third and final donation, the residents of the farm Retiro had built a temporary chapel. This small chapel was located in front of the current Rio Branco Palace, where today stands the City Hall.

The courtyard open to build this modest church comprised the block Viscount Inhaúma, General Osório, Cerqueira Cesar and Duque de Caxias; the chapel was located on the block comprised by the streets Barão do Amazonas, General Osório, Cerqueira Cesar and Duque de Caxias (Figure 2).

Figure 2: Our interpretation, referring to the block, highlighted by the black rectangle where the first chapel in Ribeirão Preto was located, in the center in white, on the City Plan credited to the Engineer Olímpio Antunes, made in 1892, as part of the studies for the implantation of sewage and supply networks (Public Archives and History of Ribeirão Preto).

According to Laureano (1973), it was around this chapel that "have emerged the first roads and the first buildings, still primitive, of a village." (P. 11). Lages (1996) adds that at this time (in 1857), according to an analysis of the packet of voters of the Historical Archives of the State of São Paulo, there were 23 voting residents, eligible voters according to their annual income; however, the number of residents was certainly much greater because at this time the slaves and women could not vote.

In August 1859 Manuel Fernandes forwarded a request to the Diocesan Bishop, D. Antônio José de Melo, to have a baptismal font in the chapel. Before the request and supported by the local population, the Bishop authorized the construction of it, but as long as it was in a "decent" place. In 1861 the resident Maria Felizarda made a large donation in favor of São Sebastião, this value, possibly instigated the vestryman in the building of a new Parish Church proper to progress of the growing region. In 1862 the permission to build a new chapel on the left side of

the stream of Palmeiras was granted by the Bishop of São Paulo, location that had guaranteed diocesan provision and patrimony legalized by the court.

Interests and disputes among residents of Barra do Retiro led the priest Manuel Euzébio de Araújo, under the guidance of the priest Jeremias José Nogueira, to demarcate a new location for the construction of the new church. The place was chosen in the patrimonial area of São Sebastião do Ribeirão Preto, where nowadays is located the 15 de Novembro Square. According Laureano (1973), while "buildings were erected, the population of the village gradually increased, to the point of having 3,000 or even 4000 inhabitants as others say" (p. 12) (Figure 3). The plots of land granted within the patrimony were placed under the institute of long lease in accordance with the descriptive request document from August 1882, from the City Council.

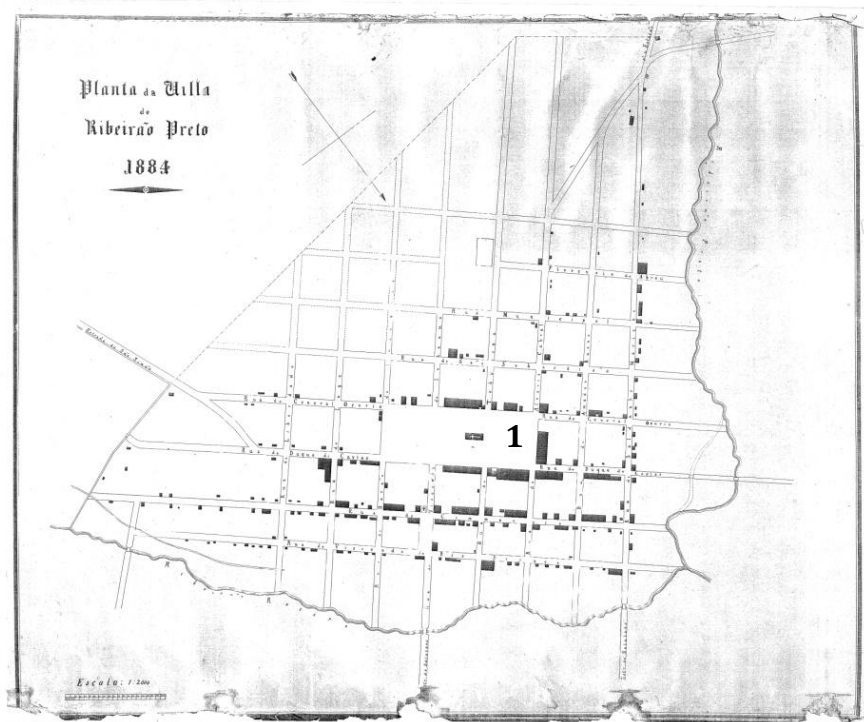

Figure 3. The village plan of Ribeirão Preto, 1884. The urban structure has as guiding point the Church (1) located in the center of a large and open space. Around the church and nearby, there are the first buildings on tenured plots (Public and Historical Archives of Ribeirão Preto).

The importance of the vestryman as a street architect, as an organizer of the orthogonal layout of the original urban core of Ribeirão Preto is of great importance. A proof of this was the murder of the vestryman Manuel Fernandes do Nascimento on February 10, 1867 by a wealthy merchant, Manuel Soares de Castilho, because the vestryman had determined, without his agreement, to open a street in his backyard.

The rapid growth of the town was considerable. On July 2, 1870, the President of the Province of São Paulo, Dr. Antônio Cândido da Rocha, elevated Ribeirão Preto to the category of Parish through the Provincial Law #51. On July 16, 1870, the Vicar of São Paulo, Monsignor Dr. Joaquim Manoel Gonçalves de Andrade, signed the decree creating the Parish of São Sebastião do Ribeirão Preto, confirming as the first vicar the priest Joseph Philidory Torres.

According to the Law #67 of April 12, 1871, it elevated the Parish to Village, whose term was dismembered from the town of São Simão His first Board was elected on February 22, 1874 and installed on June 4 of the same year.

In 1883, the tracks of the Railroad Company Mogiana reached the village of Ribeirão Preto, from this moment, the economic, social and cultural contexts have a big impact. The Church will no longer be defining the morphology of the urban space of the village, but the station of the Mogiana Company, built on the right side of the heritage lands, next to the stream of Ribeirão Preto, which is nowadays channeled because of the construction of the avenue Jerônimo Gonçalves.

In the transition of the 1870s to 1880s, Ribeirão Preto joined the "pioneer front" of coffee production, which had as a conditioning point the private property of the land. The land turned into capital and the social relations were now to be regulated by the commodity. "These relations do not end in the personal contact sphere anymore. The functioning of the market is the regulator of wealth and poverty." (Lages, 1996, p. 247).

The interest was not the proximity to the Church anymore, the proximity to the market and to the railway station were the ones that now played this role; it was the place of loading and unloading of goods, also the place of arrival and departure of people, a new meeting point, movement of ideas, ideals and culture. In the Books of Tenure in the Archdiocesan Curia of Ribeirão Preto, we can observe a continuous application process for tenured plots by the church next to the Mogiana rails (Figure 4).

Figure 4. Detail of the city plan of Ribeirão Preto organized by the office of the Força e Luz Company, 1911-1914. In this detail of the heritage we can identify the old square of the main church (1), current XV Novembro Square; at the top of the plan, the buildings of the Mogiana Company (2), and, in the nearby blocks, the occupation of the tenured lands; the left side at the top, the 13 de Maio Square, where now stands the Cathedral (3) (Public and Historical Archives Ribeirão Preto).

Ribeirão Preto had an important role in the national and international scene as a major producer of coffee, the major local landowners, the general population and the small group of religious people were organized in a Construction Committee to raise funds for the construction of a new main church at a new location from 1900 on. This Commission was formed by priest Joaquim Antônio de Siqueira, President, and Francisco Schmidt, one of the largest owners of lands producing coffee, as Vice President, and other important members of the society of Ribeirão Preto.

Furthering the studies of urban morphological structure of Ribeirão Preto to the setup of the tenured land, we observe, according to surveys conducted in the Books of Tenure along the Archdiocese of Ribeirão Preto, certain irregularity in its dimensions. According to the Book of Tenure from 1929, which transcribes the tenured lands since the 1870s approximately, we identified a wide range, for example, 17.20 meters of width by 23.70 meters of length; 7 meters of width by 23.00 meters of length; 11.00 meters of width by 23 meters of length; 9.80 meters of width by 27.00 meters of length; 20.50 meters of width by 44.10 meters of length; 11.40 meters of width by 24.45 meters of length, plus plots of land that ended up not having the geometric shape of a rectangle (Figure 5).

Figure 5: Detail of the City Plan of Ribeirão Preto, in the 1930s, where we highlight the ancient Main Church Square, where Praça XV de Novembro is located today and where you can see the settings of tenured plots of land and buildings thereon. Standing out the Rio Branco Palace (1), the Carlos Gomes Theatre (demolished) (2), the Central Hotel (demolished) (3), the location of the former Main Church (4), the Duque de Caxias street (A) and the General Osório street (B) (Public and Historical Archives of Ribeirão Preto).

The original land structure of the city has undergone changes in its form, a fact that was not restricted to drawing or factors, but the "modeling agents", who had in the social articulations their greatest contribution in the morphological constitution of Ribeirão Preto.

Conclusion

The urban morphology itself does not constitute a physical and structural analysis of the tracing and planning of a city, it also involves conflicts, joints and interests of a society or an individual.

The formation of the religious heritage in Brazil and the tenure of its lands were procedures that timidly but decisively participated in the setting of urban areas of many cities. The Institute of Long Lease which aimed to unite residents to work became a "modeling agent" of cities.

However, the tenure that should give rise to civil land during the development of the locality ended up just keeping itself in some cities, creating conflicts, agreements and especially defining the shape of urban space.

Ribeirão Preto is an example of this reminiscence, however, it is also the crystallization of a context that leads us to the colonization of Brazil, which involved the movement of people, interests, classes and religious orders in structuring and transformation of urban space. Decidedly the urban space is formed by a variety of social agents. The form follows a given sociopolitical order of the group that builds it, responding to a current sociability that regulates the use of the urban space and resources therein, thus defining the processes of appropriation and transformation of urban land.

Abstract. *“Cultural Landscape” originally appeared in the 19th century in Germany as an academic concept. As time went on, the comprehension of this concept had changed. When “Cultural Landscape” was introduced into the field of World Heritage. Because of the neglect of its academic tradition, it was defined as a sub-type of Cultural Heritage, adding confusion to identifying the heritage value and conservative management of cultural landscape. In 2013, UNESCO Beijing Office, Lushan Administration Bureau and World Heritage Research Centre of PKU established a project to improve the understanding and management of WHCL in China, presenting effective and promotable conservative utilization strategy in the case of Lushan, especially in Kuling town. The research group of PKU adopted Conzenian approach of urban morphology into Chinese practice. Research findings improved the understanding and management of Cultrual Lanscspe in China and indicated new issues of Conzenian approach to be discussed.*

Key Words: *World Heritage Cultural Landscape, Conzenian Approach of Urban Morphology, Lushan, Kuling*

Project Background

In 1996, Lushan was nominated on the World Heritage List as Cultural Landscape. Untill now there are 4 Cultural Landscapes in China on the World Heritage List including Lushan. However, there exists puzzles about the understanding and conservative management of cultural landscape. For this reason, UNESCO Beijing Office launched a research project on cultural landscape in 2010, taking Lushan as an example, for promoting a more thorough understanding of the cultural landscape listed as the World Heritage in China, as well as posing method and other suggestions for conserving and managing. The Lushan project in 2013 was taken as an advanced research under the framework of UNESCO Beijing Office, which conducted a research on use pattern of Lushan National Park based on its cultural landscape process. At the same time, an international Cultural Landscape Forum was held in Lushan, proposing references for the conservative management of World Heritage Cultural Landscape (WHCL) in China on the List and the Tentative List.

Participants and Purpose

Under the sponsorship of Mercedes-Benz (China) automobile sales co. LTD, UNESCO Beijing Office established a partnership with Lushan National Park Administration Bureau and invited the World Heritage Research Center of Peking University as academic adviser. Together with Ministry of Housing and Urban-rural Development P.R.C., national and international experts and scholars as well as the officer of heritage sites, following activities are conducted: 1.

Research on use pattern of Lushan National Park based on its cultural landscape process; 2. World Heritage Cultural Landscape forum; 3. Paper collection and Lushan Statement of Intent.

The purpose of the project is first of all to improve the understanding and management of WHCL in China, presenting effective and promotable conservative utilization strategy in the case of Lushan, especially in Kuling town, where the conflict of conservation and utilization is the most incisive. Secondly, the purpose of the project is to launch Cultural Landscape Forum, to create a platform for the discussion of Chinese WHCL conservation and management.

Process and Output

After signing the contract, the World Heritage Research Centre of Peking University immediately started preparation, such as gathering basic data, making investigation plan and etc. From March to September 2013, research group conducted multiple investigations in Lushan under the academic mentoring of Professor Jeremy Whitehand and Mrs. Susan Whitehand. The investigation covered every single building in Kuling town. Based on investigation data, historical records and maps, taking Conzenian approach as methodology, the research on use pattern of Lushan National Park based on its cultural landscape process, especially the case study of Kuling town, is completed.

From October 24th to 26th in 2013, the cultural landscape forum was held in Lushan as scheduled. Participants are project stakeholders, administration bureaus, representatives of WHCL, reporters and local communities. During the forum, World Heritage Research Center of Peking University made precise introduction to the research report. Professor Jeremy Whitehand from the University of Birmingham made a key note speech about Conzenian School of urban morphology and WHCL theories and practices. After discussions on WHCL heritage value, conservation and management strategies, consensus are achieved in the form of “Lushan Statement of Intent”.

Significance

First of all, about the theory and practice of urban morphology, this project explored the possibility of Conzenian Methodology to Chinese WHCL practices. Cultural landscape is physical space entity as the result of human activity intervening natural process, which can represent the evolution under the influence of both human and nature. From the perspective of town, this kind of physical spatial entity is shown in the form of a mosaic of the remains from different historical period. Town plan, building type and land utilization as three elements of urban form, are carriers of heritage value. Based on a large-scale map, a dynamic developmental perspective can help not only with precise spatial identification of heritage value carriers, but also overall historical interpretation of heritage value. Character regions based on 3 components of urban form complex system can reflect the space and time character of townscape with hierarchy, which can be helpful for administrative management and set conservation strategies from micro-scale to macro-scale.

Secondly, about World Heritage Cultural Landscape, this project mitigated the existing confusion in the field of world heritage. Cultural landscape as an academic concept has a long history, which can be traced back to the end of 19th century in Germany, when Schluter identified cultural landscape as the objective of geography and generated systematic methodology. However, during the successive spreading, the nature of this academic concept was changed. When “cultural landscape” was introduced into the field of world heritage, people had little knowledge of its academic background. Cultural landscape was defined as a sub-type of cultural heritage, adding confusion on the existing misunderstanding of this concept. A misinterpretation of cultural landscape as a type of heritage may lead to serious problems, such as misidentifying heritage values, choosing wrong methodology to conduct heritage practices, and blocking conservative management effect. In this project, the research group of PKU systematically traced the academic history of “cultural landscape”, reviewed UNESCO

documents of WHCL and sorted out a clear developmental route of cultural landscape from the academic origin to the heritage practices. By this way, the project somehow mitigated the existing confusion in the field of world heritage.

At last, this project is an exploration of the suitability of British urban morphology tradition to a different cultural background. To be specific, what may happen when Conzenian School met Chinese town. The reflection of research problems and achievements is helpful to World Heritage conservation and management. This research is also an important case study to promote the cross-cultural comparison of Conzenian School.

Figure 1. Lushan Statement of Intent, source: www.unesco.org.

Academic Research and Conclusion

This research, paying special attention to Kuling town, studied the use pattern of Lushan National Park based on its cultural landscape process. The goal of it is to discuss the following questions: 1. How to propose an efficient methodology to study World Heritage Cultural Landscape? 2. How to use the methodology to carry out a case study in a heritage site of World Heritage Cultural Landscape? 3. How to apply the methodology and its research result in the practice of conservation and management?

Research Methodology

The two main methodology of this research are cultural landscape process analysis and Conzenian approach of urban morphological analysis. Process analysis is the basic method and was applied to the analysis of Lushan as a whole, while the Conzenian approach, focusing more on the townscape, was applied to Kuling.

For more detailed method, documentation analysis, fieldwork, morphological analysis based on large-scale plans and statistic method were taken.

The Evolution of Lushan Cultural Landscape

Lushan is in the middle and lower reaches of Yangtze River, and near the confluence of Yangtze River and Poyang Lake. Meandering is the main feature of northern Lushan, which helped shape a beautiful ridge-valley landform. Southern and northwestern parts of Lushan have a series of bluff layers and a lot of peaks. The highest peak of Lushan, Han Yang Peak, is within

the southern part. There are some canyons between the mountains and more developmental terraces in outlying region. This is the natural base on which Lushan cultural landscape has been developing.

Overall, until the end of 19th century, Lushan had been developed naturally and in a low pace. At the very beginning, people only lived in the foothills or the plain down Lushan. When Buddhism and Taoism were spread to Lushan, people began to have more activities in the mountain and settled more towns. In Ming and Qing Dynasties, the population of Lushan grew quickly, while religion and Academic Culture declined. Later in the late Qing Dynasty, with the invasion of foreign countries, the worldly development in the mountain became more intensive and mainly focused around Kuling Town. And the trend remained today as well. After the Reform and Opening, tourism flourished and the ancient relics of Lushan had a chance to restore.

The cultural landscape process of Lushan features in: human activities stretching from the foot to the top of the mountain; the pattern of human activities changed from the scattered to centralized pattern; development activities being secularized and more intensive.

Figure 2. The cultural landscape evolution process of Lushan (influencing factor).

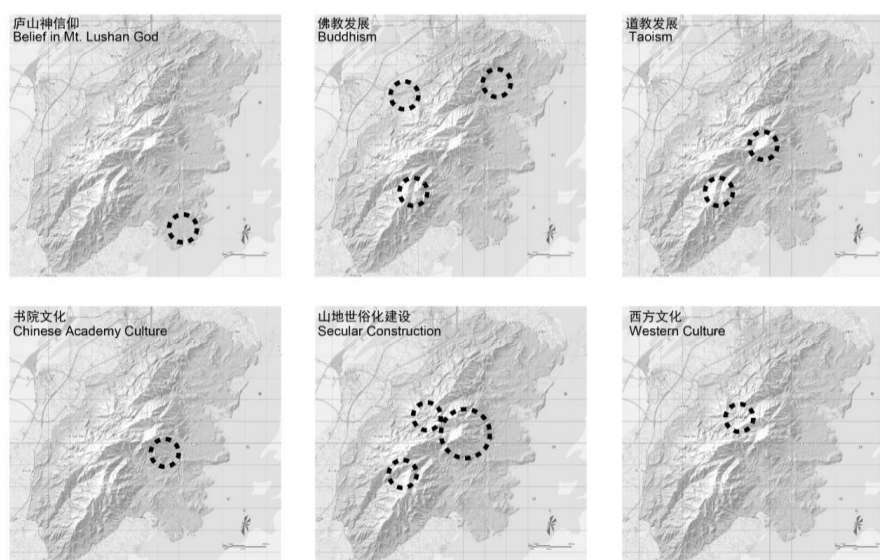

Figure 3. The cultural landscape evolution process of Lushan (location).

The Evolution and Value of Kuling Town Cultural Landscape

During the historical development of Kuling Town, there were varied cultural and political switches and socio-economic requirement, leading to different construction features, which were shown in space as particular morphological characteristics. According to the existing characteristics and historical development, morphological period of Kuling could be divided into five:

Figure 4. Morphological Period of Kuling.

Pre-urban Period (-1895)

Kuling Town, located in the north part of Lushan, involves the East Valley (Changch'ung Valley), West Valley (Dalin Ch'ung Valley) and the relatively narrow and long saddle between the two valleys. Before Edward Little's exploitation of Kuling, there existed some Buddhist and Taoist temples in this area, where secular developments were rare and only a few villages scattered around.

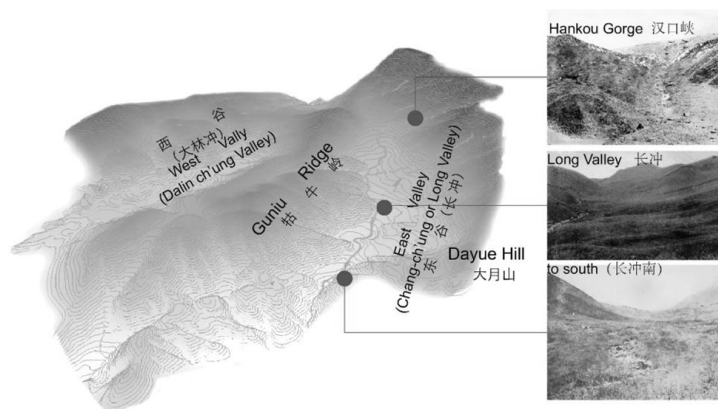

Figure 5. The natural landscape of Lushan.

Little's Period (1895-1928)

After the Second Opium War of 1858, Hankou including Kiukiang became a trading port and thereafter many foreigners came to the neighborhood. It is unbearable hot in the summer of Kiukiang, thus the foreigners were eager for a summer resort. In Dec. 31st, 1895, the Twelve Testation of Guniu Ridge (牯牛岭案十二条) were signed and thus the exploitation of Little in East Valley became legal. He divided the land into plots and sold them to foreigners of many countries to build villas. Yishenwa and Lulin area were also developed by other missionaries. In

1904, the local government rented another 900 mu land in Caodipo, Xiachong, Houzi Ridge and Dalinchong to Little, thus the size of summer resort was enlarged.

Along with the development of the town, the need for service people increased. Thus Yaowa, in the neighborhood of Kuling high street, became the settlement of these people.

In the beginning of Kuling's development, the first road to well link Kiukiang to Kuling via Lotus Cave and Jiandao Gorge was built. This was the first road to well link Kiukiang and Kuling. As for internal transportation, it was divided into rectangular plots with Changch'ung Valley as the core under the influence of topography. Little controlled the plots divided by the roads to about 3.7mu. One villa was built in the middle of a plot and facing the valley along the hill. They were linked to main roads through individual paths. Around the villa plants were acquired. In this period, the dominating building types were bungalow and detached house, both the popular type in temporary foreign countries. For instance, No.86 West River Road and No.29 Zhihong Road. The main construction of this period was for residence, while as the town developed, the service installation were also constructed and improved, such as the Linsayd Park located in the centre of the town as public open space, and Kuling Street as commercial street. There were also religious, official, education buildings as public building utilization.

Figure 9. High Street in Edward Little's period (Left) and modern time (Right), (source: Left-Lushan Administration Bureau, right-author).

Republic Period (1928-1949)

In 1928, the Nanjing Republic government established. Since 1930s, Lushan was regarded as Summer Capital. In this period, the residents in Kuling Town are mainly Chinese with a few foreigners in the west valley. The main transportation and travel path network was constructed. The former path to Kuling from Lotus cave via Jiandao gorge was gradually abandoned and the Lotus-Kuling new road was used instead. The main constructions of this period were residence and public buildings. Most of the newly-built architects, mainly in the west valley, covered relatively large area. The overall style remained as the former period. Kuling also constructed some public buildings, among which the Three Buildings, namely Lushan Library, Lushan Mansion and Auditorium, are of significance. Three Buildings reflected the turn of building idea from following the west to maintaining both European characteristics and traditional Chinese style. In this period, the land utilization pattern was basically similar to that of the former period. municipal installations such as waterworks and power plant were improved and in residential areas as well as commercial areas repletion process happened in the morphological frame of the former period. Besides, Shengli Village and Chaoyang Village began to prosper.

Figure 10 The Three Buildings: Lushan Library (left), Lushan Mansion (middle), Auditorium (right), (source: Luo Qi (2008). p154\157\162).

Early Period of P.R.C (1949-1978)

In May 1949, Lushan was liberated and Lushan management office set up. Three important meeting of Chinese Communist Party Central Committee were held here, during this period, a lot of service people came to Kuling and some new sanatoriums and hotels were newly built. In the aspect of external transportation, the north road began to work in 1953 and in the same year, Lushan motor station was constructed. In 1971, the south road began to work. In the aspect of macro structure of the town, the northern part of the Kuling developed rapidly. Under the socialist system, the ownership of land and the distribution pattern changed dramatically, which contributed to the change of the townscape characteristic of Kuling Town. Firstly, the land in the town were owned by the government, thus for townscape, the significance of plot boundary decreased while that of the individual buildings increased in the distribution process. Secondly, with the Danwei system introduced, the organization pattern of urban space changed dramatically, as well as the function and ownership of buildings.

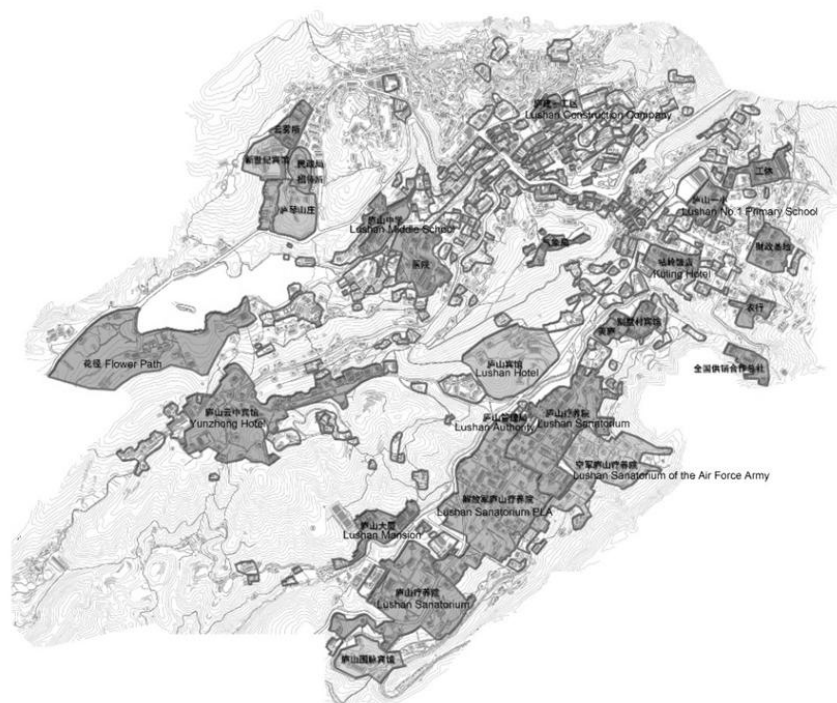

Figure 11. Danwei in Lushan, 2013.

Open Policy Period (1978-)

In 1996, Lushan was listed in World Hseritage List as Cultural Landscape. Since the Reform and Opening-up, the rapid development of economy stimulated the travel industry of Lushan. Some sanatorium made some change and served also travelers instead of only the members and guests of the Danwei and other tourism installations were also built. Newly-built buildings of this period tried to conform to the existing buildings through learning from the building language of them, thus formed a mixed style. Kuling Town became the town in a national park, thus the function of it changed and consequently the land utilization. The alteration to tourism service function of many other-function buildings is remarkable. The numble of hotels, stores and restaurants increased rapidly.

The Heritage Value of Kuling Town

Based on the morphological analysis of Kuling Town, heritage value of three levels could be identified as follows: Firstly, the site selection and the process of construction of Kuling Town reflected the organic integration of human activities with natural environment, which formed characteristic cultural landscape. Secondly, in the evolution process of Kuling Town, the East Valley and West Valley were closely related as organic parts of the whole townscape, which together illustrated its value of cultural landscape. Thirdly, the present amounts of micro-scale physical remains, such as street pattern, boundary marker, and outer wall, etc., embody the cultural landscape, which are of conservation value.

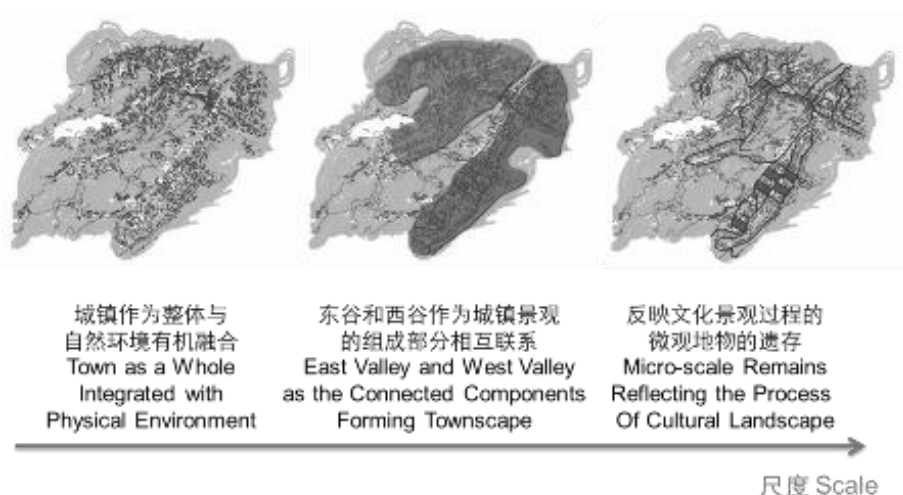

Figure 12. Multi-level Reflection of Heritage Value.

The Strategy Analysis and Intensity Threshold Measurement of Kuling Town

The current cultural landscape of Lushan thus became the accumulating record of its development process. The multiple factors contributed to the differentiations of cultural landscape in different regions of Lushan. The conservation and management should be based on the differentiations and apply different character regions. Based on the principle of integrity to represent the cultural landscape process, the principle of independence to delineate the geographical spatial unit and the principle of operability to implement conservation and management, a two-hierarchy conservation and management units are demarcated, namely 5 rank-1 units and 20 rank-2 units.

Next, the measurement of intensity threshold was carried out to evaluate the development intensity of Kuling so as to provide quantitative basis for the strategy of conservation and management. Firstly, units are divided based on the property rights of the buildings and the landscape around. The current situation of each unit is assessed as U_0 , then the threshold, also marked as U_{max} , is figured out according to the current situation and future expectation. The Differential Intensity (DI), is the result of U_{max} minus U_0 , which measures the space between current and expectant intensity, could have three possible values. Negative value means a larger current intensity than the expectation, which would possibly need fixation; Positive value means improvement could still be made; zero value, which means an accordance between current situation and future expectation, maintenance and preservation in small scale is enough for these area. Development intensity of a unit is decided mainly by natural condition and activity, we built an evaluation index system consists of 3 first-level and 11 second-level indexes, combining with AHP Approach to evaluate the development intensity and intensity threshold of each unit.

Finally, according to the threshold analysis results of each unit, detailed and appropriate strategies of conservation and management were proposed.

Figure 13, Conservation and Management Units (First-Hierarchy)

3.Early Settlement of Service People (Yaowa); 4.Fringe Belt Area; 5.Scenic Area.

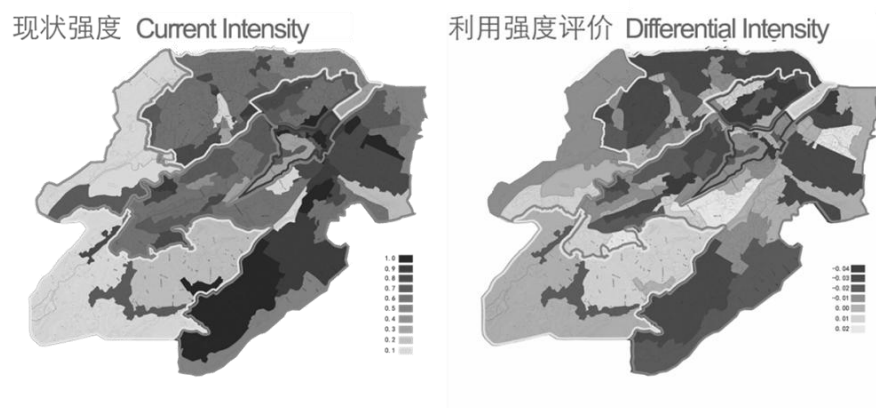

Figure 14. Intensity analysis of the Conservation and Management Units.

Discussion

A Chinese-specific Way of Space Division and Organization

Under the socialist system, the ownership of land and the distribution pattern were changed dramatically, which contributed to the change of the townscape characteristic of Kuling Town.

Firstly, the land in the town were nationalized, the significance in the distribution process of plot boundary decreased while that of the individual buildings increased. Secondly, with the Danwei system introduced, the organization pattern of urban space changed dramatically, as well as the function and ownership of buildings. Danwei, combining the function of production and life, integrated the work, residence, commerce, education and recreation functions in a compact space, forming a relatively independent complex.

Danwei has several space forms. Firstly, the space integrity of Danwei compound is strong, with wall as its ownership boundary, and inside the wall, the function of work, residence, commerce and education is orderly organized. The typical Danwei compound was often designed by the Soviet experts with its layout and architectural design carried out on the spare land. Secondly, the space of non-compound Danwei is less integrated, generally without wall and the organization of all kinds of function depends on the specific condition of the site. This situation occurs in the case of spatial redistribution of existing substances, the government took building as its distribution unit and allocated it based on the principle of living adjacent to the workplace. The spatial distribution and organization of Kuling Town belonged mostly to the latter situation, besides, there were expansion and construction of residential buildings in the vicinity of the existing building. Some large Danwei which has higher demand for space got buildings in more than one site, so that the space integrity was further weakened.

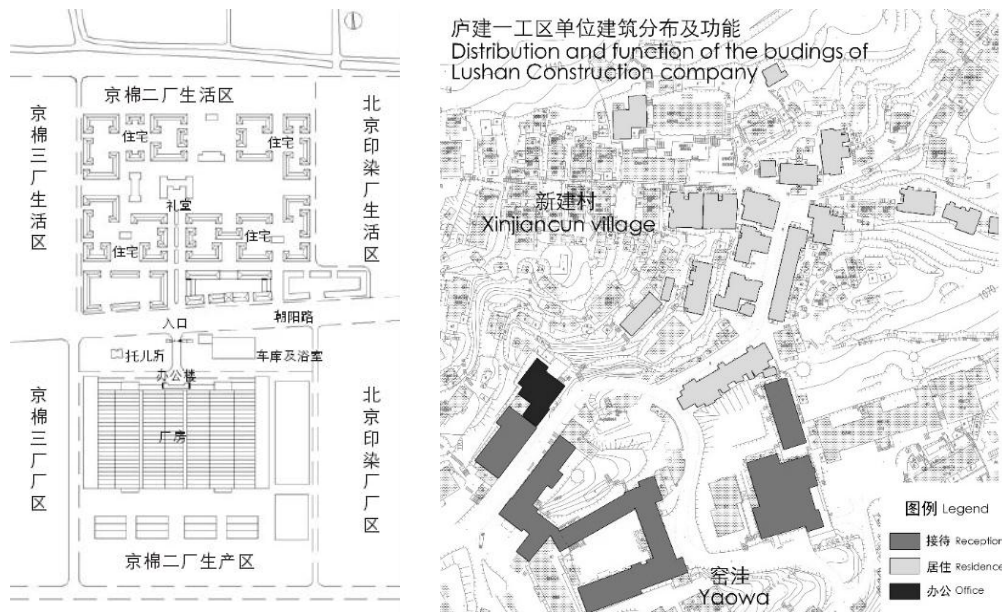

Figure 15. Plan of Beijing No.2 Textile Factory (Left), Distribution and function of the buildings of Lushan Construction Company (Right), (source: Left-Zhang Yan (2009), Right- drawn by author).

The Decline of Importance of Plot Boundary to Urban Landscape

According to the experience of England, town plan, including street pattern, plot pattern and block plans, is dominant among the three basic elements of townscape and the most resistant to change. However, it is really different in Kuling, where the importance of plot pattern decreased. When revolutionary change happened and the ownership system changed totally, the plot boundary which contains relatively less capital lost its dominance over the following evolution of townscape.

This was exemplified by No.8 middle 6th road and No.33 west river road. These two villas, belonging relatively to the Air Sanatorium and Lushan Sanatorium, were very close to the road, which went through the original plot. These two villas were both in No.109 plot in Little's

period. It was subdivided into 109B, where No.33 west river road locates, and 109C, where No.8 middle 6th road locates. Nowadays, the door plate, the ownership as well as the physical remaining of the two villas show little relationship to the original plot.

Figure 16. Newly constructed road dividing original plot.

The Deficiency of Research Material

The research method of Conzenian School of urban morphology has a high demand of richness, historicity and continuity of research materials, such as large scale map, historical map and local chronicles. And the microscopic scale and accuracy of its methodology lead to the higher accuracy of these materials. However, China has been in war in a long period of history, especially when the western society was going through rapid scientific and technological development, China was concentrating on the post-war recovery. As a result, Chinese have failed to map and collect the historical data, and the scientificity and accuracy of the materials was restricted, which had a negative impact for the popularization of Conzenian methodology in China.

From urban sprawl to a compact city policy: the primacy of process over form

Cristina Soares Cavaco

CIAUD, Faculty of Architecture, University of Lisbon.

E-mails: ccavaco@fa.ulisboa.pt, cristina.soares.cavaco@gmail.com

Abstract. *Cities represent a challenging demand for contemporary society. In a time when the majority of the world population is already living in cities, urban areas are showing an exponential enlargement, having heavy impacts on social, economic and environmental sustainability and a tremendous footprint on the globe. The canonical response to the problems of extensive urbanization has been the return to a compact city model, as a less predatory and more sustainable type of urban form. Nonetheless, the subject is controversial and has generated misconceptions related with the compact city concept itself, with the advantages and disadvantages of urban concentration and with the misunderstanding of urban density. After the compact city has been presented as a paradoxical fallacy, new perspectives are now emerging opening the debate to a wider point of view, less related with the city shape itself and more oriented to the process of planning, managing and governing the urban development; i.e. to a compact city policy rather than a compact city model. This article aims at exploring the contemporary debate between urban sprawl and the compact city, especially addressing the question of whether urban form is crucial in pursuit of urban sustainability objectives.*

Key Words: Compact city, urban sprawl, urbanization, urban policy, sustainability

Introduction

It is of general consensus that last decades have brought deep transformations into the spatial organization of cities. Beyond the changes in demographics and population density, critical changes have happened in the form of cities, namely throughout phenomena such as the urban sprawl - low density settlement patterns, leapfrog unplanned developments, spatial segregated land uses, large outward incremental expansion, widespread commercial strips, disseminate land ownership and land uses governance (Angel *et al*, 2005; EEA, 2006; Font, 2007).

Urban sprawl is therefore considered a challenging demand for national urban policies and territorial development agents due to its high impacts on energy inputs, land consumption and soil sealing. This is especially critical in Europe where cities have traditionally been much more compact (EEA, 2006).

Envisaging progress towards a sustainable urban development, doctrinal thinking and literature on the benefits of a compact urban development for a sustainable urban form came up, becoming a dominant doctrine on urban planning theory after the release of the Brundtland Report (1987) which consigned the emergence of the agenda of sustainability. The compact city has become one of the most discussed concepts in contemporary urban policies and much attention has been put into the relationship between urban form and sustainability (Elkin *et al*, 1991; Breheny, 1992; Jenks *et al*, 1996; Rogers, 1999; OECD, 2012; UNHabitat, 2012).

Nonetheless, several criticisms came forward arguing against the abusive position that considers the compact city as a sort of panacea for the ills and problems of extensive urban developments (Neuman, 2005; Westerink *et al*, 2012; Hofstad, 2012; Echenique *et al*, 2012).

The paper aims at discussing the accuracy and timeliness of compact city policies, reviewing the rationale behind the compact city and exploring the relationship between urban form, urban processes and urban governance.

The paper is divided in two different parts. The first one is dedicated to the discussion of the compact city concept striving for an understanding of its trade-offs with both urban sprawl and

sustainability. The paper explores the origins of the concept, the controversies stemming from the relationship between urban compactness and sustainability and the rising up of processual approaches over shape-oriented strategies. The second part is addressed to compact city policies. A survey on standard compact city policy tools and approaches is carried out, as well as on the emerging trends that underpin the need for an integrated policy approach. Discussion includes a review on the increasing importance of urban governance's delivers, as well as a reflection on the role of urban form on the scope of a comprehensive compact city policy.

Compact city: does urban form really matter?

The rise of the compact city concept

Compact urban settlements have long since taken as an immediate response against the problem of urban sprawl. Sprawl has been pointed out as one of the most decisive menaces to sustainable development, broadly recognized as having a huge carbon footprint and a high social, economic and territorial impact. The return to a compact city model arose and grew up as a natural reaction, running counter to urban sprawl.

The compact city concept was first coined by George Dantzig and Thomas Saaty in 1973. Focused on putting forward a more efficient city model on the use of space and resources, the proposal presents a visionary circular city for 250.000 people composed by different levels and platforms where activities are distributed in a vertical way. High-densities developments, clear boundaries, diversity and mixed land use are the main physical and functional characteristics for a city spatial model where an independent government, a clear identity and a self-sufficient daily life economic basis also make a difference.

Some of the principles established by Dantzig and Saaty had already a root on the beginning of the 60s, stemming from Jane Jacobs's theories and writings. In the book *"The death and life of great American cities"* (1961), Jacobs addresses a fierce criticism to the 20th century modern urban planning doctrines and zoning urbanism, fostering diversity as a reference concept on upholding livability and the quality of life in urban areas. Mixed-use neighborhoods and streets, short blocks layouts, building variety and density are given as the crucial features Jacobs considers being at the foundation of vital and diverse cities, alive at different times of the day and with high levels of pedestrian permeability.

It was by the end of the 80s that the concept has conquered a widespread popularity. With the release in 1987 of the Brundtland Report, sustainable development has become part of the mainstream. A first definition of sustainable development came up then, widening the scope of the concept to economic and social issues (far beyond the more restrictive environmental perspective) and putting the emphasis on the principle of intra and intergenerational solidarity: *"sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs"* (Zwart *et al*, 2012).

Other subsequent events such as the Rio Summit in 1992, and some doctrinal papers such as the European Community's "Green Paper on the urban environment" (1990) and the Urban Task Force's final Report "Towards an Urban Renaissance" (1999), also had a decisive role on the rise of the compact city as a sustainable model for urban development.

Since then, much attention has been put into the relationship between urban form and sustainability, being the compact city some sort of sponge-like concept that congregates several divergent perspectives, related either with the physical dimensions of urban form (size, shape, land uses, distribution of open spaces, etc.) or other parallel issues where mobility and transports represent a significant share (Jenks & Jones, 2010). Above all, the purpose has been achieving alternative solutions and adequate planning strategies to contain urban expansion and protect open land and natural resources. Elkin *et al* (1991), Breheny (1992) and Mike Jenks *et al* (1996) are among the literature that have contributed the most to ascertain a close correlation between urban form and sustainability, questioning to which extent the form of cities affects a

sustainable urban development. In Northern America, New Urbanism and Smart Growth movements have also acknowledged the benefits of a compact urban form influencing the adoption, in many states and counties of the United States, of smart urban policies (Dieleman & Wegener, 2004). After that, a range of other reflections and writings have carried out the consolidation of the compact city paradigm. In addition to the containment agenda regarding the efficiency of land use and the clear separation between urban and rural land, other issues have come up such as the protection of the countryside and open land for agriculture and ecological purposes, the reduction of car dependency and the increment of public transportation facilities and multimodal solutions, or the increase of social and economic interactions in intra-urban areas, striving for land uses mixture and proximity (Westerink *et al*, 2012).

The compact city controversy

But the problem is controversial and the compact city concept generates a series of misconceptions. On the one hand there are the pros and cons of compactness as a current urban development strategy. Notwithstanding the positive aspects related to proximity and the preservation of open land and natural resources, it is worth not to lose sight of the negative side effects coming from high densities. Urban concentration and intense land use can easily fall into crowding leading to traffic congestion, air pollution, lack of vegetation in cities, loss of open green space and insufficient affordable housing. Contemporary high density metropolises show that this is still a legitimate concern. At this point the debate raises a sort of paradox (not yet solved, indeed) in a sense that suburban developments and contemporary sprawled urban space, now at the source of centripetal stances (the compact city ideal), stem precisely from responses to overcrowding (Breheny, 1996). On the opposite side of the modern claim – “*nothing gained by overcrowding*” (R. Unwin), the current statement is more likely – “*something lost by overspacing*” (L. Mumford). Notwithstanding, the compact city paradigm is still an open issue, namely due to the inverse relation that exist between the sustainability of cities and their livability. While the first asks for higher densities, the second one suggests lower densities and less concentrated settlements (Wiersinga, 1997 *cited in* Neuman, 2005).

On the other hand there is doubt on the accurateness of the concept itself vis-à-vis the establishment of a causal link between urban form and sustainability. Whether substantial advocacy supports the benefits of higher densities and mixed land uses on reducing travel distances and generating socially vital and economically viable urban spaces, no clear conclusions arise from empirical case studies. Following extensive research, a direct relationship between urban sustainability and compactness can hardly be drawn (Westerling *et al*, 2012; Hofstad, 2012; Echenique *et al*, 2012; Neuman, 2005). Burton, Williams and Jenks are the first to recognize that “*the problem of how the compact city can deliver sustainability is complex; it depends on the relationship between the form and location of intensification, the extent of intensification, and the policy, management and wider socio-political and economic context.*” (Burton *et al*, 1996). For this reason “*caution must be exercised in assigning causal effects from the compact city*” (Burton, 2000).

In 2005 Michael Neuman reasoned that the question whether a compact urban form is sustainable does not hit the nail on the head. According to Neuman, process is more critical than form when it comes to deliver sustainability: “*conceiving the city in terms of form is neither necessary nor sufficient to achieve the goals ascribed to the compact city. Instead, conceiving the city in terms of process holds more promise in attaining the elusive goal of a sustainable city*”.

The compact city is, above all, a morphological concept. The emphasis is placed on density and compactness, and the concept is eminently addressed to the spatial characteristics of urban settlements, namely to the concentration and the intensification degree of both activities and built occupation. But, as Neuman points out by identifying “*the compact city fallacy*”, urban form is not a sufficient condition (Neuman wonders if it will even be necessary) to drive urban sustainability. He also remarks that “*the attempt to make cities more sustainable only by using*

urban form strategies is counterproductive". On the one hand a city is always a complex system to which converge, in an integrated way, a series of functions and urban subsystems, continuously subject to a multitude of interdependent processes (Dieleman & Wegener, 2004). On the other hand, sustainable development is, in itself, an extremely complex issue (Burton *et al*, 1996). According to Neuman, it comes out from five different intellectual traditions (capacity, fitness, resilience, diversity and balance¹¹²), assigning to an ongoing process where our current way of life is conditional upon the perpetuation of species and the prospect of future well-being (which represents a clear paradigm shift against the former stance where present time was solely conditioned by historic past). At this perspective, Michael Neuman advocates the primacy of process over form. It is the urban processes themselves that might be sustainable, not urban form, he says. "*Form is a snapshot of process. It is a fixed condition at any point in time*" (2005: 23), so it is by no means measurable in terms of sustainability.

The primacy of process over form

But, is spatial form a completely negligible issue when it comes to ascertain urban sustainable development? If, on the one hand, Neuman's position is absolutely pertinent and admissible attending on the etymology and the proper understanding of sustainability¹¹³, on the other hand the thoroughness of the compact city concept also depends upon the prism through which urban form is considered.

The text from André Corboz "*The territory as a palimpsest*" might bring us some expertise on the subject. In the face of the multitude of disciplines and interpretations concerning the territory as a physical and mental entity, and reasoning about what might be a fair definition, Corboz establishes that the territory is simultaneously a *process* (in a sense that it is the result of a set of natural and human processes/actions), a *product* (since it is also an artifact, i.e., the physical and spatial expression of the territorialisation of such processes) and a *project* (to the extent that it oversteps its physical existence being placed as an idea, i.e., an imaginary construction concerning the territory's mental collective representation). These three inseparable translations of what the territory is, took Corboz to claim that, besides having a form, the territory is itself a form. As such, it congregates the physical artifact plus the processes and the projects shaping it (Corboz, 1983; Cavaco, 2009). In a certain sense, Neuman also corroborates this understanding when he states "*one cannot overlook the fact that form is both the structure that shapes process and the structure that emerges from process*" (2005: 22).

Yet processual approaches have been strengthened on the planning context, especially when put into perspective and compared with zoning and blueprint planning. The explanation lies in the uncertainty that characterizes contemporary society resulting in a growing inability to predict short-term social and economic trends and therefore establish definitive physical models to accommodate future urbanization outcomes. According to Portas *et al* (2011), the city as a puzzle has come to an end meaning that blueprints - totalized frozen visions - can no longer be the standard approach to urban development. New planning and management mechanisms are needed, considering the upshots of the urbanization process in a less deterministic shape-

¹¹² *Capacity* refers the capacity of a certain habitat or place to accommodate and support a population of living beings, without compromising present living conditions as well as the habitat's future capacity. *Fitness* refers interaction over time between environment and species, attending to their mutual adaptation and evolution, especially attending to the way a given organism fits into a community or an ecosystem. *Resilience* respects the way a certain place or habitat absorb the presence of an organism and the capability it has to respond and react against the effects caused by him. *Diversity* respects the coexistence of a variety of members in a community focusing their ability to interact and adapt each other. *Balance* reflects upon the ability to search for an equilibrium especially focusing on the trade-offs between environment and development. (Neuman, 2005: 17-19)

¹¹³ It derives from *sustain* which means to "keep something going over the long run"; an understanding that is behind the thesis of the Brundtland Report – the most widespread definition of sustainable development.

oriented point of view. The decline of spatial form as the guiding issue of spatial planning coincided with the upsurge of integration purposes within the urban development strategies and policies. Documents such as the Leipzig Charter, the Toledo Declaration and the Territorial Agenda of the European Union (2007, 2011) constituted a major step, fostering the importance of integrated approach in urban development and highlighting the need for searching for close coordination between the different sector-wide approaches heading a specific territory as a target. From the Leipzig Charter “*integrated urban development is a process in which the spatial, sectoral and temporal aspects of key areas of urban policy are coordinated*”.

Notwithstanding the growing primacy of processes over form, it does not mean a space-blinding paradigm has arisen, far from it. Spatial aspects are still a relevant issue (one would say determinant issue), particularly when place-based development policies are concerned, framed by a territorial spatial-aware perspective. Whether the focus of sustainability should be placed on processes rather than on spatial form, every process or strategy with a territorial/urban impact has necessarily a spatial effect on the ground. The same as urban processes and the outcomes of every urban policy or strategy are conditioned upon the spatial and the physical features of a certain territory or urban area.

Hand in hand with integrated approaches, the territorialisation of public policies - place-based development policies - has been gaining ground. The emphasis relies on the aim of tailoring interventions to a specific place regarding place-specificities and mobilizing local actors and resources (Barca, 2009). An integrated approach in urban development is necessarily a place-based and territory-focused approach, stressing for a strategic and operational confluence between the different sector-wide policies and the urban development itself. As such, what might be the role of urban form on current urban policies? What is indeed the very potential and importance of the compact city concept for current urban policies?

Compact city policies: appraising urban processes, urban governance and urban form

Policy approaches and instruments towards the compact city

It is recognized by OECD that the “*compact city is one of the most discussed policy approaches in contemporary urban policies*” (Matsumoto, 2011; OECD, 2012). In recent years, compact city policies have increasingly integrated national urban agendas at a European and International level (OECD, 2012; UN-HABITAT, 2012). A wide sort of strategies, measures and recommendations falling into the basket of compact city policies and covering a range of different types of policy intervention (regulatory, fiscal, strategic, direct investment, partnership, informative) have been adopted by a number of European and OECD countries, confronted themselves with the increasing problem of urban sprawl and with the disadvantages coming from a widespread urban development.

The containment agenda framing both land use efficiency and open land protection stays ahead of the curve. At this level regulatory tools are the standard policy approach, being urban growth boundaries for limiting urban expansion and distinguishing urban areas from the rural land at the top of the list. Concepts vary, going from the “green side of the urban frontier” in which the greenbelts are included (Westerink *et al*, 2012), to a more abstract approach committed to the institution of urban perimeters and containment boundaries. While with greenbelts a zone barrier is physically created around urban settlements usually with a dual-purpose of preventing urban development and providing green amenities and leisure facilities for city-dwellers, in other cases a polygonal boundary is established beyond which no other constructions than agricultural structures are allowed, having the unique intent of controlling the enlargement of the urban footprint. In Europe, the United Kingdom and the Netherlands represent, probably, the primal examples. In England, the establishment of the Green Belt Policy dates back from 1935, first limited to London city and then extended to other areas by the Department for Communities and Local Government, in 1995 and 2001 (Rogers, 1999; OECD,

2012). In the Netherlands, the compact city has also performed a policy issue since the 70s, centered on the preservation of open agricultural areas and natural environments, namely the Green Heart for the Randstad (Geurs *et al.*, 2003; Dieleman & Wegener, 2004). But they are not exclusive. Other similar concepts and situations happen, not only in Europe as is the case of the *Ceinture Verte* in Paris, but also in the United States (e.g. the urban growth boundary of Portland in Oregon) as well as in Asia (e.g. the greenbelt of Hong Kong, China) and Australia (Dieleman & Wegener, 2004; OECD, 2012). In Portugal, the concept of the urban perimeter might be integrated in this type of planning tools, although the resulting delivers in the last decades are not very encouraging; quite the reverse, in fact.

Another regulatory instruments respect the establishment of urban development and urban design strategic guidelines, at a national, regional or even sub-regional/metropolitan scale. The territorial structure framed by the settlement pattern and the network of urban areas (urban network) is, at this point, a major aim and concern. Czech Republic offers an interesting reference. A national urban policy framework was release by the Ministry of the Regional Development: *Principles of Urban Policy* (2010), establishing a conceptual and operational framework for the implementation of urban policy in the country. Polycentric development is drawn as one of the principles and main strategic guideline. In Portugal, polycentrism also figures as a primal spatial development strategy, being one of the six main objectives of the National Spatial Planning Policy Programme, approved in 2007 by the Parliament.

Far beyond the narrow understanding where the compact city model is exclusively addressed to a monocentric urban structure, polycentrism has been advocated has an alternative for a more balanced spatial organization of cities and urban areas. The polycentric development is actually one of the driving policy aims stressed at the European Spatial Development Perspective (approved by EU Member States in 1999). Rooted in Ebenezer Howard's theoretical model of satellite cities, it has been capturing followers within the scope of the compact city debate, arising on a range of different concepts and approaches. Dutch planning is once again among the examples stressing the concept of *clustered deconcentration* since the 70s. The idea was recovered by Thomas & Cousins who have introduced the notion of *decentralized concentration*, envisaging a new possibility for a compact city form. Slightly different from the most popular Peter Calthorpe's approach of Transit Oriented Development (TOD), *decentralized concentration* explores a new conceptual regional city form based on the idea of virtual compactness, where diversity might stem from a flexible dispersed urban structure of decentralized concentrations (1996). *Polycentric compactness* is another flourishing concept, this time committed to the Paris metropolitan planning framework (2008).

Indeed, the polycentric interpretation of the compact city has opened doors to a new focus of attention: accessibility instead of proximity. Westerink *et al* point out that "*travelling time has become more important than distance*" (2012), foster linkages between transport and urban form, i.e., between land use and mobility. In fact, anti-sprawl planning strategies combining both land uses and transport policies represent a significant share of compact city policies. Transit Oriented Development from North American New Urbanism movement (Calthorpe, 1993) is a well-known example. Notwithstanding the critical panorama of urban development in North American, a number of innovative approaches have been carried out, striving for more compact and mixed-used urban forms, as well as for more sustainable urban systems. Portland, Oregon, is a good example, having implemented since the 70s a containment policy, first with the definition of an urban development boundary, secondly following a TOD. A regional public transportation system based on light-rail and a dense bus network was implemented, thereby signaling the hubs where mixed-uses and higher density nucleus are to be developed (Dieleman & Wegener, 2004). In Vancouver, Canada, a similar concept (Frequent Transit Network - FTN) has been introduced, shaping land use in development corridors accordingly to the frequency of public transportation transit (OECD, 2012).

Density and mixed-use requirements lie among the regulatory tools as one of the most popular approaches. Besides establishing maximum densities, zoning codes are also settling for minimum densities to ensure the necessary intensity of uses in specific areas. Accordingly,

mixed uses have become an increasing concern, following a similar approach at zoning ordinances. The French *Code d'Urbanisme* offers good reference on the matter since new regulatory guidance came to allow the municipalities to require minimum densities on greenfield and brownfield developments near public transportations nodes. London planning also comes up with recommendations on density requirements which took several London boroughs to establish threshold limits.

Regulatory tools are sometimes orchestrated with a range of complementary fiscal mechanisms such as: development taxes or development fees, as well as sub-density taxes, not only to charge developers for urbanization costs, but also to capture the capital gains coming from land use changes and thereby fighting against sprawl; split-rate property taxes on behalf of brownfield developments rather than greenfield leapfrog developments; parking and congestion taxes to discourage the use of private cars. Subsidies and other compensatory mechanisms are a common procedure as well, ranging from incentives to developers and households to invest in specific priority areas such as transport nodes and historic centers, to amenity bonus, namely social infrastructures, granted by developers in exchange for higher densities permits (OECD, 2012).

Trends for a comprehensive policy approach: the challenge of integration

Regardless of whether the term *compact city* is a good one to describe the intended goals of urban sustainability and offset the adverse effects of sprawl, it is rather the outcomes of compact city policies that concern the most as a valuable approach for current Green Growth and Sustainable Development debate. Far beyond the focus on urban form, density and compactness, compact city policies are already “*raising the level of the game*” to a more holistic approach where the spatial structure of cities and the patterns of urban settlement are just a piece among others in the multidimensional process of urban development. Figuring as a policy approach rather than a spatial model, compact city policies have gradually incorporated new policy targets and instruments regarding quality of life, livability, urban efficiency, energy savings, risk management and prevention, etc., far beyond the elementary stance of protecting the environment and the natural resources by simply containing urban expansion and controlling growth.

Based on a study launched by the OECD involving several member countries (*Compact City Policies: Comparative Assessment*, 2012), five current urban trends were identified that underpin the accuracy and timeliness of more comprehensive compact city policies: (i) The most evident trend concerning compact city policies is *land consumption*. It regards both the increasing rhythm of land-take and the emerging discrepancies between land-take and demographic growth. More than a half of the world population is already living in cities and it is expected that in 2050 it reaches about 70% (90% in OECD countries). Nevertheless, the critical issue is not simple the increase population in urban areas, but rather the fact that land consumption is exceeding significantly the rhythm of population growth. Between 1950 and 2010, built-up areas expanded by 171%, whereas population growth did not overcome 142%. At the same time, the geographic footprint of cities is also changing radically. The spatial distribution of the population within cities shows that the urbanization dynamics has been followed by an exponential growth of peripheral areas. Statistical data prove that, between 2000 and 2006, urban growth was faster in suburbs than in urban centers, leading to new greenfield developments rather than infill and brownfield developments. At this point, compact city approaches have focused on the establishment of policy instruments specifically driven to endorse sprawl containment and to protect open land from predatory uses; (ii) *Energy prices* is also a traditional issue within the scope of compact city approaches, particularly related with disperse settlement patterns vis-à-vis the general increment of energy prices. According to OECD data, over the last 40 years the increase in world energy consumption has been followed by a general rise of energy prices. A widespread and sectorized urban configuration, particularly in cases where activities and mobility patterns are very much dependent on road infrastructures

and the use of private car, might become especially vulnerable to the variability of energy costs, bringing negative side effects to the economy and competitiveness of such territories. Policy instruments have been specifically driven to endorse urban mixture and efficient location patterns, along with transport policies to encourage public transportation in detriment to automobile; (iii) *Demographic changes* are one emerging issue attending to the expected population dynamics along with the change on demographic patterns. At this point, contrasts arise from demographic trends, posing a risk to social and territorial cohesion. On the one hand, population growth presents variation rates that do not keep up with land take dynamics. A decline is even expected at short-term for some of the OECD countries, Portugal including. Concerning demographic patterns, discrepancies exist, as well, at a regional and metropolitan scale, since positive variation rates in some areas means the shrinkage of others, namely urban cores and historic centers. On the other hand, ageing population coming from birth rates decline and longer average life expectancy, coupled with a change on households size (average has reduced from 2.95 to 2.55 from 1980 to 2008), ask for appropriate house types and a balanced territorial distribution of local services and social infrastructures. Combined policy mechanisms on density and mixed-use requirements have been a common procedure, while urban regeneration policies focused on the conversion of brownfields and existing buildings and sites, associated to other housing policy instruments, might open the door to increasingly inclusive approaches; (iv) Another emerging trend is *global warming* and *climate changes* to which cities are particularly responsible and vulnerable. Two issues are especially meaningful. The first one is the rise in average temperatures across the world (from 1.7°C to 2.4°C up until 2050; from 4°C to 6°C at long-term). To a great extent, they are consequence of the high levels of global greenhouse gas emission, which are expected continuing to raise. Cities are one of the largest producers of CO₂. The second has to do with sea-level rise affecting in particular coastal areas, knowing that it is at coastlines where urbanization has indeed a major incidence. Mitigation measures as well as climate changes adaptation approaches are the two main policy branches that might converge to a comprehensive compact city policy; (v) The challenge of a *sustainable economic growth* stresses the need for combining a proactive environmental safeguard with the imperative of economic growth. In 2008, the outburst of the subprime crisis has pushed traditional economies where Europe is included into an extremely hard condition. The situation is even bad for countries whose national economies, nourished by the promising advent of neoliberal policies and the expectancy of deregulated markets' profits, were largely dependent on the building sector and the real estate market. Urban sprawl cannot be decoupled from that. The negative effects affect not only the private sector, but also the central and the local governments' finances. The problem is not only the dispersion and fragmentation of urban areas *per se*, with obvious losses of efficiency burdening both the environment and the economy. It is also the amount of vacant houses and buildings that result from unregulated real estate markets and easy credit facilities, as well as the extensiveness of road network infrastructures, whose conservation and maintenance costs have huge impacts on the limited budgets of local and central governments. Focus goes to land use policy instruments, regulatory or fiscal, especially driven to endorse a paradigm shift, from expansion to contention and regeneration, namely through the establishment of compensatory mechanisms to regulate and balance land prices and the real estate market provide, at the same time, a rationalized offer of high-quality public goods and services.

The wide spectrum of urban trends and the cross-cutting and interdisciplinary nature of policy measures ask for a comprehensive urban policy approach, necessarily involving a coordinated implementation of the several specific sub-policies. Having as an ultimate goal the achievement of urban sustainability in terms of environmental quality, social equity and economic viability, a comprehensive compact city policy is thereby oriented to a multidimensional process of planning, managing and governing the urban development, rather than staying hung up on a frozen spatial model framed by the reference (and the myth) of the compact traditional European city (Sieverts, 1997).

The master key of urban governance

The transfer of the policy focus from urban form to urban processes has brought another imperative issue: urban governance. Governance arrangements are indeed a fundamental step to endorse the objectives of integration and coordination of a comprehensive urban policy. *“Cities need to break away from compartmentalized approaches and to integrate formerly fragmented policy actions by taking the spatial, economic and social dimensions of urban development; an approach that will help them to integrate all these dynamics, activities and services. Multilevel urban governance has been advanced as the government model that meets most of the requirements imposed. (...) it can be defined as an arrangement for making binding decisions that engages a multiplicity of politically independent but otherwise interdependent actors – private and public – at different levels of territorial aggregation in more-or-less continuous negotiation/deliberation/implementation (...)”* (Tasan-Kok & Vranken, 2011).

Fitted as an integrated territorial approach¹¹⁴, one can say that a compact city policy is therefore a place-based, multi-scaled, multi-level, multi-sector and multi-agent approach: (i) Place-based since it is oriented towards the specificities of each territory and the political framework of each region and country (Barca, 2009). In fact, there is no single comprehensive compact city policy applicable to all cities and metropolitan areas. Depending on the characteristics of each territory and urban area, spatial strategies might differ both in terms of compaction degree and urban structure, either monocentric or polycentric. On the other hand, policy instruments also differ from region to region, requiring the necessary local/regional adjustments; (ii) Multi-scaled since it has into account the broader context of functional urban areas which include urban cores - intra-urban areas, but also urban hinterlands – the city-region, and the links and relationships that are forged between cities and urban centers. The functional metropolitan area is therefore the reporting spatial unit of a compact city policy, recognizing the need for cities/municipalities to collaborate in a same region (OECD, 2012). Spatial strategies concerning an efficient and sustainable urban development cannot be closed in local individual approaches. Municipalities have much to gain from sharing certain collective services and infrastructures and a broader inter-municipal policy of public transportations. A cross-cutting approach between different scales and levels of territorial aggregation is therefore a demanding challenge; (iii) Multi-level since it requires the vertical integration and coordination between the different government levels, local, regional and national. Although it is generally agreed that a compact city policy especially falls into a local/metropolitan level, the fact is that there are several policy measures pursued at a national level that have direct impacts on the spatial structure of urban and metropolitan areas. Land use policies are one the situations requiring the vertical coordination between the different government levels; (iv) Multi-sector since it is a cross-cutting policy requiring the horizontal integration of different policy agendas; a crucial step to maximize synergies, complementarities and policy outputs. The objective is not only to ensure the dialogue of the diverse sectoral policies, but also the ability of working together in order to provide coherence between policies envisaging the achievement of a consistent holistic territorial approach; (v) Multi-agent since it asks for the participation and involvement of the several urban actors. With the fall of the welfare state paradigm, government responsibilities and functions have progressively been transferred from the central state to the local governments and from the public sector to private stakeholders. Urban development has become an activity shared by a multiplicity of different agents, ranging from public agencies and semi-independent public organizations, to private stakeholders and enterprise, non-governmental organizations and the civil society.

¹¹⁴ Integrated approach is defined as *“the incorporation of diverse sectoral policies (such as employment, education, environment, culture, spatial policy, social policy) at diverse organizational levels (local, regional, national, intergovernmental instances) to achieve a holistic territorial policy approach”* (Tasan-Kok & Vranken, 2011).

A comprehensive policy addressed to sustainable urban development is therefore dependent on the implementation of a good governance model able to promote *"an interactive framework in which diverse actors at diverse scales of governance are actively involved in the policy making and implementation"* (Tasan-Kok & Vranken, 2011).

Conclusive remarks: the place of urban form

In the last pages a survey was done on the compact city as a response to urban sprawl, regarded either as a spatial model or as a comprehensive urban policy focused on sustainable urban development. Discussion has showed that the emphasis has been changing from urban form (i.e. cities' spatial model) to urban processes and governance, from shape-oriented blueprint planning approaches to integrated approaches focused on a processual multidimensional planning. Whilst a controversy persists on the accurateness of the compact city concept, especially when it comes to recognize a direct relationship between urban form and sustainability, national urban agendas at a European and international level have been striving for the implementation of a sort of policy measures that meet the goals behind a compact city strategy. Compact city policies are now one of the most popular urban policy approaches in OECD countries. A set of emerging urban trends, ranging from energy to climate and demographic changes, as well as to economic growth, stress and highlight the need for a comprehensive urban policy, where compact city policies also fit.

The question, however, remains on urban form. What is the place of urban form in contemporary urban policies? What about the territory-focus and the spatial-core of public policy approaches? What part do they play within integrated process-oriented approaches? How pertinent might be urban form in contemporary policies for cities?

Compact city policies might help us to better achieve a balanced ground. If one is led to agree that processes, along with governance, shall acquire a prominent position on a context of disseminated government responsibilities and multiple actors' engagements, form is still a relevant issue. According to A. Corboz, the territory is itself a form, being at the same time a physical artifact and the processes and ideas that have shaped it. Urban form, as well as urban space, cannot thereby be left behind on a territory-focused approach.

In fact, the territory-focus has been gaining emphasis on the context of the European Cohesion Policy, especially after the territorial dimension has been introduced in the Treaty of Lisbon (2007), joining economic and social cohesion. The rationale of place-based development policy approaches has been gradually settled down since then, stressing the importance of territorial context and spatial linkages to catalyze the results of policy measures focused on economic growth, social inclusion and environmental quality.

Nevertheless, there is still a long way to achieve. Exploring the crossings between place-based development policy approaches and urban morphology might be an interesting way to go. Compact city policies are well positioned to support such a playground.

In fact, the distinctiveness of compact city policies (among other policies focused on sustainable urban development) is neither the reference to a model of a compact city nor even the aim of looking for urban compactness as an urbanization trend. It is rather the fact that, notwithstanding the emerging primacy of processes over form in contemporary urban policies and planning approaches, spatial form shall still be a reference issue. If, on the one hand, there is no such a thing as a sustainable urban form (evidences show that no conclusions can be taken whether compact urban development is more sustainable than a sprawled urban form), on the other hand spatial criteria shall be determinant on integrated urban approaches.

"Compact city policies offer a comprehensive policy approach that addresses urban sustainability goals by influencing the use of urban space." (OCDE, 2012:51)

Abstract. *In the cities, street system offers the framework of building forms. In macroscopic, streets define the pattern of blocks, and could be identified as building lines of the beginning of “building behaviour” (architecture) in microcosmic. Since lands had been restrained by planning, planned roads are laid and patterns of original settlements had been covered. Therefore, this brings out two layers of urban fabric, the planned and non-planned roads, which are so called “accomplished roads”. Due to the overpopulation post WWII, the accomplished roads conflict to the plan pattern makes blocks far away from the pursuit of satisfying demand of housing through automobile dependent urban planning and zoning. To interpret planning gap caused from accomplished roads, the evolution of building forms follow two perspectives: 1) Building forms follow the management of zoning of the urban plan by the time. 2) The floor area depends on the width of “Face roads” (Oliveira, 2013). According to the investigation, Blocks are heterogeneous of building forms with the accomplished roads exist. The change period of building form follow the rule of the street system by the time building behaviour took place, usually in the term of motionless along accomplished roads while those along planned road reflect the urban plan immediately.*

Key Words: planning gap, accomplished road, building form, Yonghe

Introduction

As the Athens Charter (Charte d’Athènes) manifests the four functions of dwelling, work, recreation and transport, it has become the highest principle of urban planning and development. According to the principle, urban reconstruction after WWII was rational and the overpopulation make the built up area develop rapidly to satisfy the demand of housing (Hall, 1988). In the late 1950s, due to the penetration of vehicles, the automobile oriented planning concept had been developing. Straight and wide geometry pattern became the central idea of road planning. Furthermore, since lands had been restrained by planning, blocks become the basic unit of zoning, no matter whether the goal of urban plan is; the planning based on zoning should be trend to homogeneous. For the perspectives above, the modern urban planning should be rational, geometric and homogeneous.

Nonetheless, such automobile design urban planning shattered the existed urban fabric in built up area. The accomplished roads, which own the characteristic of irregular, bending and heterogeneous, make the vision of blocks somehow different from the expectation and the surface feature will be showed up by building forms.

As street system offers the framework of building forms, the arrangements of buildings have been locked in the frame that the street systems construct. In microcosmic, the street line became building line, which is the beginning of building behaviour. The building line has legal validity and makes the buildings have a corresponding layer of street system. Also, the height of the buildings shall be rendering proportional to the width of streets. Both layers of street systems are thence owns decisive influence on building forms.

Due to the urban built up area will never be blank, the two layers of street system overlap each other make the city face with the fabric neither orderly nor organic (Figure 1). Therefore, according to the evolution of time, how will the forgotten impurities, accomplished roads, give rise to the planning gap from the expectation of urban plan?

Figure 1.The current pattern generated by the cover of original fabric.

Gap between the ideal and reality

Urban form can be understood at different levels of resolution. Commonly, four are recognized, corresponding to the building/lot, the street/block, the city and the region (Moudon, 1977). To interpret the planning gap, rules and tools pursuing ideal urban plan would be elaborated to express the datum and the difference can be count. According to the planning theory post WWII and the progress in technology, the great demand of housing from the overpopulation was tried to settle efficiently and try to become homogeneous, while Acts manage land and building utilization in strict control. The interaction between urban plans and laws plays the rational development role in the cities.

The beginning of gap

About a century ago, Henry Ford founded the mass production line of Ford Model T, the car then produced in great quantity and the vehicles ownership significantly increased. In Asian cities, private car and motorcycle ownerships were rising quickly by the 1970s, especially in the middle-income cities of Malaysia, Thailand and Taiwan. To match the demanded of rising private vehicles, the influence of Western automobile-oriented ideas was spread all over the world. The prestige of the United States tended publicizes highways and cars as the way of the future. The Western consulting firms also influence or conducted the transport or urban planning studies by the early 1970s, and they used the standard urban transport planning (UTP) process that had been developed in and for American automobile-oriented, suburban-style cities, which implement the idea of wide and straight.

"A city made for speed is made for success." (Le Corbusier, 1929). Based on the automobile design urban planning, the planned roads then become straight and wide, the geometric streamlines then provide security and speed passage for vehicles. The planned roads not only provide the service of transport but also segment the city into grids which are called blocks.

The Post-World War II baby boom and political immigrants make the explosion population crowd into the cities and suburban area. Buildings were rapidly duplicated in the blocks to fulfil the demand of housing comply the arrangements of street systems before the very first urban plan. The overpopulation is uninterruptible in decades and makes the urban planning necessary to control the development. Planning based on zoning is then become the universal principle.

Zoning, the device of land-use planning, separates one set of land uses from another. Early zoning practices were occurred in New York in 1916. In 1930s, Asian cities try to westernization and the zoning method start to restrain the land use of plots, based on the minimum unit, blocks. The management was only on the plane but gradually changing to

control the volume and height of buildings. Hence, the development under the same zoning management should approach to the homogenous (Litman, 2009).

While zoning and planned roads were laid on the original pattern and make complex circumstances in the blocks. The negligence of original pattern become two layers of street system, *planned roads* and *accomplished roads*.

Characteristic of street systems

The ground plan is the component most resistant to change, rejecting a major capital investment, particularly in the case of the street plan (Conzen, 1960). Street systems define the pattern of blocks and offer the framework of building forms. Moreover, street systems offer the beginning of building behaviour (Architecture).

As the beginning of building behaviour, street system offers the building line of building base to make sure the demarcation of land use. In compliance under the provisions, the building behaviour is then allowed to take place. (Talen, 2011) These also strengthen the fixity of street system of the original land use. Ratio of building height to street width is another management from street system in microcosmic. The ratio is positive correlation. The wider the street system is, the higher the buildings can be built up. The height of *Face road* is the element decides the building height by Acts. Buildings along the two layers of street system should be able to predict from the principles above.

At last, when the street system is laid and confirms the use of being public passage, the streets only broaden and increase by the urban plan. The street systems are barely removed that after the first urban plan the accomplished roads are sometimes being broadened and extend and the planned roads are laid on the prime lands.

The impurities and gap

In the ideal state, the result or transition of urban plan should be estimated by street system (planned roads) and the management of zoning.

$Y = \alpha X_1 + \beta X_2$ the ideal state

Y = The result of urban plan

X_1 = Street system

X_2 = Zoning

Actually there are still other factors in the model which output the real urban morphology. The planning gap is cause from the factors that we ignored, and accomplished road is one of kind (Pissourios, 2013). The accomplished roads are not irregular and own the same right as planned roads under the management of Acts. The characteristics of accomplished roads make the actual state unable to achieve the purpose and maximum benefit the urban plans expectation. Therefore, the factor was seen as impurities which interfere in the operation of the ideal state which cause the planning gap.

$Y = \alpha X_1 + \beta X_2 + \gamma X_3 + \varepsilon$ the actual state

X_3 = Accomplished road

ε = Planning gap

The less of cognition of planning gap makes the new urban plans carried out harder and harder. The circle become vicious and causes real estate market failure and development costs were waste.

Accomplished roads are the trace of human activity and exist all over the world. In a highly competitive between cities, the less of planning gap will enhance the competitiveness.

Model

Restriction

From the point of views above, accomplished roads would be certainly discussed and the influence would be confirmed by a model investigate the buildings evolution along different layers of street systems.

In the model of evolution of building based on street systems, there are two restrictions to eliminate the influence of other factors.

First, the zoning of study area must be the same. The construction of land use, building coverage ratio and floor area ratio are equal in a single block, which make the building utilization and the maximum development intensity of each building base under the same construction. The purpose of the restriction is to confirm the homogeneous of blocks from the vision of urban planning.

Second, there was neither major facility in nor near the study area. If there were major facilities around, the service level of public facilities will be evidently different. Due to the gain in benefit of redevelopment, the possibility to bring out the urban renewal will be arising. If the urban renewal occurs, the change period of buildings will not only follow the characteristic of street systems and the development will be implemented by big area beside the regular rule of one by one reconstruction.

In summary, the usage of the following model will be operated in the study area which under the same zoning control and without major facilities. In the situation, the impurities factor from street system will be show of.

The evolution of building form based on street systems

Due to the fact that street systems influence the buildings in both macro and micro scale, there are some components in the model of the evolution rule. According to the advance of time, the factors will evolve through the time line. The three components are street system, building and urban plan: (i) Street system: There are planned road and accomplished road in the street system. Owning the same right on law to construct the development of buildings. The accomplished roads exist from the beginning of the model and the planned roads were laid after the first urban plan.; (ii) Building: The city has always been characterized largely by the individual dwelling (Rossi, 1966). The building form changes from the technology and value of the time, and the floor areas grow because of the demand of housing increase and under the management of urban planning. (iii) Urban plan: The very first urban plan occurred because of the demand of housing reach the standard. When more and more people gathered into the area, the demand change and the new urban plan come to relieve arrange the demand of housing.

The building component depends on the street system because of the framework and the right on law. The street system and building depend on urban plan from its management while the plan is try to fulfill and properly configure the demand of housing. Thus urban plan realize the demand of housing when it reach a standard or become saturation. All the components above alert by time. The relationships between the components are shown below.

Due to the components on the model, there will be accomplished roads and buildings along them, the forms of the building will be low in height and with little floor area.

When the demand of housing rise to reach the standard, the very first urban occurred and the planned roads are then laid. During the period of time, the buildings along accomplished might changes by the time, following the first urban plan's management. Along the planned roads, buildings are higher and the floor area would be larger due to the width of planned roads are much longer.

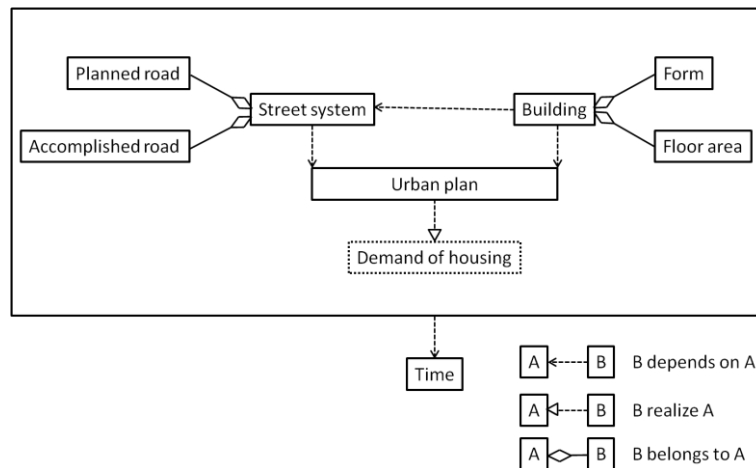

Figure 2. The relationships of the model components.

When the demand of housing are again full and the floor areas are no longer afford it, a new urban plan try to use the land more efficiently and offer more floor area. According to the ordinance of new plan, the buildings along planned roads are getting higher and the floor area would increase. Otherwise, the buildings along the accomplished roads limited to the shape of accomplished roads that are hard to expand and the shorter street width, the capability of offer floor area is low that make the buildings hard to renew then maintain their original form. The buildings between the accomplished roads and planned roads might change the Face road of buildings. When the buildings' change to planned roads from accomplished roads, the benefit makes the buildings higher but the floor areas won't be as much as those along the planned road because of the framework obstruct the expand. Thus, there will be three evolution progresses in the model.

Figure 3. The evolution of building form based on street systems.

The evolutions are shown above and the colour level represent the age of the building. The darker the older. The area of the blocks represents the floor area of the building. There are 3 stages of urban plan evolvement: (i) Buildings along accomplished roads: The accomplished roads exist from the beginning and the change period of building forms are slow due to the framework and restriction of height.; (ii) Buildings along planned roads: The planned roads occur from the very first urban plan and the buildings along comply with the management then the height and floor area have high quantity; (iii) Buildings between accomplished roads and planned roads: At the beginning the buildings are along the accomplished road, when the demand of housing is high enough, some buildings change their Face road to the planned road and the building will be as high as those alone the planned roads but the floor area would be less because of the framework of accomplished road to expand.

Case Study

The study area: Yonghe city

Yonghe, a city little settled before WWII, was the country side out of Taipei and the land use are nearly farm land before 20 centuries. The street system then was close to the rivers. After WWII, Yonghe has a great population explosion after the war. According to the proximal location beside the Capital city, the overpopulation influx into the Yonghe area because of political policies and industrialization. There were more than six hundred thousand military and their family move in to Taipei Basin, and had the highest population density in Taiwan and second in the world (after Manila in the Philippines), with over 41,300 people per square.

In 1957, the first urban plan of zoning management was published. The population rapidly increase and went out of control. The government then uninterruptedly published new plans to satisfy the great demand of housing. The planned roads are then laid from the urban plan of different periods. By that time, the original patterns are ignored and covered by the zoning management which surrounded by the planned roads.

In Taiwan, the very first zoning is started from the act of Taiwan City Planning Order in 1937. The act divided lands into seven kinds of zones. The construction management is loose and only restrict the plane extend of buildings. To maintain the public facility service level, the floor area ratio was controlled in 1980s. The maximum building form has been controlled from urban planning and building control acts. The buildings thus being controlled in 3-dimension way, according building coverage ratio, floor area ratio and land use.

According to the Acts, thousands of accomplished roads are identified in Yonghe. There is a main accomplished road which called "Xiulang Road" near the Xindian River from 19 century. The road was the main route to connect the villages and the land use around are farm lands. Although the plan road are laid in turns, the original pattern of Xiulang Road still maintained even the land use of it should be residential use in the urban plan. The pattern even sometimes becomes the base of the new planned roads.

To understand the accomplished road as the impurities in the blocks, three blocks which cover Xiulang Road are selected. The blocks are in same residential use and without major facilities around. The planned roads around the blocks were laid in the different period of time which represents the management from different urban plan. Thus, the buildings in the blocks and along the planned roads are the main object in the paper to be observed.

Experimental result

On the basis of the evolution model, we observe the building components of the building time and the height. The buildings are along the accomplished roads and three planned roads. The street system here was built in different times and width. (Table 1).

Table1. Characteristics of street system.

	Layers of street system	Width(m)	time
Xiulang Rd	Accomplished road	8	19 century
Dehe Rd	Planned road	18	1974
Houde St	Planned road	8	1990
Chenggong Rd	Planned road	18	1995

The investigation shows the characteristic of the buildings and they are separated into 4 clusters by statistics analysis. Figure 4 shows the samples are mostly distinguished in the first two clusters, which means the development of the study area happened in great majority between 1980s to 1990s (Figure 4).

Figure 4. The clusters from the building time and height.

The figure 5 shows the locations of different kinds of clusters. According to the building height and the time, the building forms are similar and try to solve the population problem at that time. (Table 2): Cluster 1: The buildings are before 1978 and the heights are all under 5 floors. Cluster 2: The buildings time is between 1978 and 1989, and the height are 4 to 5 floors. The divergence of cluster 1 and 2 is from the urban plan published in 1976 and the floor management is loosened. The new bridges connect to the Taipei city make the study area having another period of population explosion and 5-floors apartment were commonly use in the solution copy in a huge amount.

Cluster 3: The buildings time is between 1988 and 1999, and the height are 6 to 7 floors. The buildings follow the urban plan published in 1985. After 1988, the floor area ratio was controlled and building behaviours are then shrinking.

Cluster 4: The buildings time is in 1998 and the height are 14 to 15 floors. The buildings follow the urban plan published in 1997. Near the 21 century, it is prevalent to build apartments higher than 10 floors, citizens living in the small residential unit.

Table2. Characteristics of clusters.

Cluster	Building time	Building height(floor)
1	Before 1978	<5
2	Between 1978 to 1989	4~5
3	Between 1988 to 1999	6~7
4	1998	14~15

The composition of building clusters is diverse in a single block. According to the proportional analysis, Cluster1 and 2 accounted for the largest proportion which means buildings in the study are over 30 years and lower than 6 floors. As a densely populated area, new urban plans try to release population pressure but the situation still exists (Table 3).

The figure 6 show the comparison with model of evolution of building based on street systems, the figure shows all kinds of progress in the study area. Buildings along accomplished roads: Before the very first urban plan, build up area is few and scattered in the study area. Lands along Xiulang Rd were little settled and were in agricultural use. Buildings along Xiulang

Rd are almost classified into cluster 1 and 2. Buildings of cluster 1 were settled before the blocks were designated. When overpopulation took place, buildings of cluster 2 were stuffed in the blocks with the period of planned road were laid, and the buildings forms were mostly attached apartments. Buildings along planned roads: Buildings along Chenggong Rd are almost classified into cluster 3 and 4. Buildings of cluster 3 were settled with the period of Chenggong Rd were laid, and the buildings forms were mostly attached apartments with elevators. Buildings of cluster 4 were settled with the new urban plan published and the building forms are apartments more than 10 floors which are in the shape of big area squares. Buildings between accomplished roads and planned roads: there are all 4 clusters of buildings between Xiulang Rd and Chenggong Rd. The buildings were replaced through time and follow the management from urban plan of the time. The different of the buildings from cluster 1 & 2 to 3 & 4 is that the buildings transfer the building line from accomplished road to planned road. The wider the road is the higher the building can build to get more floor area. Hence, the buildings of cluster 4 in the ribbon are narrower or in the shape of column compare with those along Chenggong Rd ascribe to the slender building base.

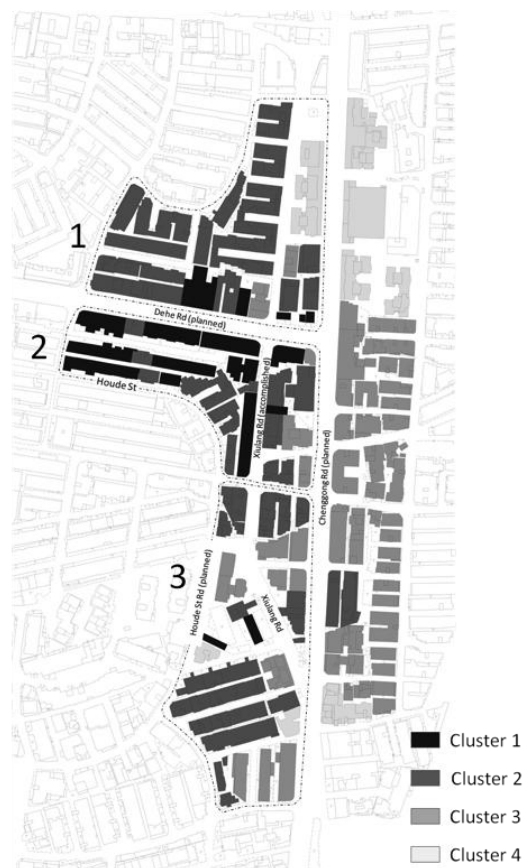

Figure 5. The arrangement of the clusters.

Table 3. Proportion of clusters in a single block

	Cluster1	Cluster2	Cluster3	Cluster4
Block 1	21%	61%	7%	11%
Block 2	41%	48%	7%	0%
Block 3	25%	59%	8%	8%

Figure 6. Building forms of each cluster.

According to the clusters distribution, the buildings arrangements are truly following the framework of street systems. In the micro observation, though the building behaviour follows the building line and width of street, there were no obviously relationship between them and nor the cluster characteristic. The R-squared of building line and the clusters is only 0.22, and the R-squared of road width and the clusters is only 0.31. Actually, the effect from street system to building is not isometric. The open up period of road and the process interaction might have more significant influence of the change period of building form.

Figure 7. The aerial photograph in 1974 and the cluster arrangement along Dehe Rd.

Towards the investigation and analysis, there were two spatial deformation circumstances. As figure 7 shows, even Dehe Rd is a planned road; there are still many buildings of cluster 1 along it. Before the urban plan, there was an important branch of Xiulang Rd. After being broadened and became the planned road in 1957, the buildings are still root along the road. The buildings here are in the shape of strip and complex in the proprietorship which make them hard

to be renewal. Therefore, we can tell that the attraction of development chance of planned road is hard to resist the fixity of accomplished roads.

Figure 8. The aerial photograph in 1974 and the cluster arrangement along Dehe Rd.

In block 3, there were a building of cluster 4 which strangely surrounded by the narrow alleys. The building base is triangle and the streets are all less than 7 meters. Under the normal circumstances, building start the building behaviour from the building line in front of the building base and the Face road should be the accomplished road or planned road attach the building base. According to Building Technical Regulations, the building can make the Face road become Chengong Rd, due to the narrow streets and no road wide enough attaching the building base, which makes it much higher than other buildings around (Figure 8).

Conclusion

In the pursuit of orderly and efficiently of land utilization, urban planning tries to make the city rational, straight and homogeneous. Zoning and automobile oriented planning are the tool and concept to fulfil the value. The negligence of the original pattern fixity shatter the original pattern then causes gap that is hard to be forecasted. The accomplished road irregularly cutting the blocks and limit not only expand of building base but also change periods of building renewal.

View as the impurities in blocks, the accomplished road effect the homogenous balance and bring out the planning gap. When architecture is viewed as the city, buildings can represent the actual results of operations from urban planning. Building forms and floor area depends on street system from the control of law. Both of components rely on the urban plan when the demand of housing isn't satisfied. The evolution model is then verified by the case study and can be sum up as the following consequences.

- 1) From the distribution of clusters in the study area, buildings in a single block with existence of ancient accomplished roads are obviously diverse and far from homogenous.
- 2) The buildings along accomplished roads maintain the very first building form, while those along planned roads reflect the urban plan in fast change period. Besides, buildings between the two layers of roads are in a great variety of forms which reflect the demand of housing partly.
- 3) As the transformation of the model, planned road which was broadened and extend from accomplished will maintained the building forms before the planned road was laid. The forms were depending on the characteristic of the original accomplished road. We can say that the evolution of building will follow the rule of the street system by the time building behaviour took place.

According to the investigation, Blocks are heterogeneous of building forms with the accomplished roads exist. The change period of building form follow the rule of the street system by the time building behaviour took place, usually in the term of motionless along accomplished roads while those along planned road reflect the urban plan immediately.

Since accomplished roads were sure to be one of the factors bring out the planning gap, the coefficient of the factor can tell the degree of heterogeneous in blocks. In addition, the continual exploration of planning gap can be interpreted the ownerships and real estate market.

Events-driven morphological process – A case study of Auckland's waterfront

Toby Shephard, Luke Gibson

University of Auckland, New Zealand.

E-mail: tobyshephard@windowslive.com, lgib022@aucklanduni.ac.nz

Abstract. *In order to contribute to international literature concerning the process of morphological change, this paper focuses on a study of the city centre waterfront in Auckland, New Zealand. A Conzenian analysis of the space, with reference to historical economic and cultural contexts, is used to derive a narrative explaining of urban modifications of the waterfront fringe belt. Auckland waterfront has undergone redevelopment across a 200 year period. Beginning with the morphologically invisible culture of aboriginal Māori occupation to the maritime industry of the 20th century and to recent modern regeneration, the waterfront has changed from a low-density fringe belt to one pocketed with commercial and residential intensification. This is particularly true of the western side of the city's waterfront. Our research finds that much of the recent urban regeneration of the last 15-20 years is the result of preparation for the hosting of major international events. These include the America's Cup 2000 and 2003 and the Rugby World Cup 2011. We find that major events have accelerated urban form change on Auckland's waterfront and thus might provide noticeable contrasts between planning units. Such building form and layout might then been seen as a physical expression of a sporting culture and tourism based economic necessity. A discussion of the impact of international events upon urban place-making and planning is included with a view to establishing broad morphological periods of development along the Auckland waterfront as well as informing the manner and typology of urban reconfiguration that major international events require.*

Key Words: *urban morphology, event-led development, Auckland, Māori, waterfront redevelopment*

M.R.G. Conzen fathered the urban morphological analysis in the mid 20th century. Conzen's approach to urban examination consists of a consideration of three elements of urban form: the ground plan, building fabric and land use. For Conzen, an analysis of urban morphological form was coupled to an understanding of the historical development of land areas (Whitehand, 2001). This analysis has led to the identification of plan units within the urban structure of cities. Plan units are defined as land areas with a shared history of development, similar ground plan, building form and land use. As such, plan units represent pockets of historical development and their identification aids in an understanding of the underlying principles of urban development and land use.

The Conzenian principle of morphological regionalization has been under represented in international research outside of Europe (Siksna, 2006; Gu, 2010). However the work of Gu (2010; 2013) has provided valuable insight into the organisation of one city in particular, Auckland, New Zealand, using the Conzenian approach. Gu (2010) describes the present day plan units expressed on the Auckland waterfront. The waterfront itself is identified as a fringe belt, a broad subcategory of urban form first identified by Herbert Louis (Whitehand, 1988). Gu (2013) has investigated the application of this concept to the New Zealand examples of waterfront redevelopment. This paper seeks to add to the analysis presented in Gu (2010) by critiquing the driving force behind the modification of Auckland's waterfront fringe belt area.

Fringe belts are defined as low-density stretches of urban land, which usually contains transport facilities, parks, public utilities, cemeteries, and institutional land uses (Whitehand, 1988). These broad sections of the city are located on the fringe of more dense development, including the CBD, and often constitute public open spaces and include prominent public amenities (Whitehand, 1988). Ports and their surrounding areas are identifiable as expressions

of fringe belt land use in the Conzenian morphological analysis (Whitehand, 2001). Fringe belts are characterised by low density, public or institutional land use with large, irregular lot sizes and building footprints (Whitehand, 2001). As such they can be imagined as a 'breathing space' for the CBD: in that they have the capacity to support the growth of commercial and residential activities within the CBD.

Research objectives

Waterfronts globally are undergoing post-industrial redevelopment (Gordon, 1996; Breen & Rigby, 1994; Oakley & Johnson, 2013). As these spaces are developed and plan units modified, cities face challenges establishing new waterfront identities. Oakley and Johnson (2013) in particular have presented a fascinating post-colonial reading of the Port Adelaide and Melbourne's Docklands; in their paper they find that colonial powers, intent on extracting the economic value of a waterfront via ports and industry, transformed the aboriginal understanding and use of the waterfront space entirely. We find that such a reading, informed by a Conzenian understanding of urban plan units, is valuable in Auckland, New Zealand.

The identification of plan units on the Auckland waterfront has led to the documentation of the fringe belt area around Auckland's CBD by Gu (2010). In recent years development within the waterfront fringe belt zone has been characterised by the reappropriation of land plots for higher density land uses on smaller plots. On the Auckland waterfront the Princes wharf and Viaduct Harbour are such examples where high-density residential and commercial land use has become established in areas previously associated with marine and shipping industries (Gu, 2010; Gu, 2013). This process is known as the alienation of the fringe belt. As fringe belt alienation continues, the historical information held within the built form, land use and urban fabric of a plan unit is similarly modified. To what extent can modification erase cultural histories along Auckland's waterfront? And what is the driver for said alienation upon the Auckland waterfront?

This research paper aims to establish plan units along the Auckland waterfront at three points in time in order to demonstrate the morphological evolution of the space. These are pre-colonial Māori occupation of the area in 1840, the height of port and marine operations in 1940s and the present day waterfront. Progressive shoreline reclamation is also depicted to illustrate the modification of the original pre-European occupation waterfront over time.

This paper has been structured first to include a discussion of colonial appropriation of the Māori occupied Auckland waterfront, which is then analysed using a Conzenian lens of urban morphology to illustrate how modern development is rewriting the colonial waterfront in much the same way. The paper is divided into the three broad morphological periods identified through this research. These are pre-contact Māori occupation, colonial reclamation and modern redevelopment centered on the economic stimulus of international events.

The objective is to understand that tangible changes to the waterfront are expressed as the result of economic, institutional and social forces (Moudon, 1997). These being the economic realities of development and social attitudes towards waterfront use. Each broad period is found to be clearly paired with the economic realities of its era in so far as built structure and land use reflect profitable and realistic uses and sit within commonly held worldviews of that time. In recent years the driver for urban change on the Auckland waterfront, the driver for alienation of the fringe belt, is identified as both the reduction of port activities and subsequent release of port land; and the real and potential economic stimulus of the hosting of international events.

Event-driven urban redevelopment is not an uncommon development strategy (Chalkley and Essex, 1999). Event-led development helps to 'fast-track' urban development/regeneration because of economic stimulus. This is undoubtedly true in New Zealand. Benefits include improving transport, cultural facilities and global recognition and prestige (Chalkley and Essex, 1999). The Olympic games are clear global examples of event-led development and their legacies are clear in the infrastructure and built form of cities such as London, Beijing and

Sydney. These include airport capacity, hotel accommodation, public transport, water and sewage systems and urban landscaping; all are needed to cope with the capacity these events demand (Chalkley and Essex, 1999; Ritchie, 1984). As a city begins to acquire said infrastructure and capacity, the city attains a reputation for holding events, which increases the likelihood of hosting further events in the future (Chalkley and Essex, 1999). This indicates that Auckland could expect to hold more of these events as it begins to gain a reputation and begins to construct the type of infrastructure that is needed to facilitate these events. This has already been shown by the 2011 construction of 'The Cloud' for the Rugby World Cup on Queen's wharf – an events facility for public screenings.

The legacies of event-led development extend far wider than transport infrastructure and stadiums. The Eiffel Tower is a legacy of the Paris Exposition in 1889 and the Royal Festival Hall in London is a legacy of the festival of Britain held in 1951 (Chalkley and Essex, 1999). While these physical legacies are now tourism boons in their own right, event-led development can also lead to social and economic hangovers. A magazine in Canada in 1994 polled locals for their estimation of the legacy of the 1994 Victoria Commonwealth Games; the most common answers were increased taxes, increased real-estate prices, a new pool, debt and increased tourism (McCaw, 1994). These insightful answers clearly speak to the largely short term economic benefits that characterise an international event. How well has Auckland fared following the hosting of the two large international events: America's Cup yachting competition in both 2000 and 2003 and the Rugby World Cup 2011? To what extent does the modification of land use for these events within the fringe belt erase the history of colonial maritime waterfront use? How does this echo the impact of colonial modification of the pre-colonial Māori occupied waterfront?

From a morphological perspective, the short and long term economic benefits of event-led development must be weighed against the lasting urban form that such events create. In Auckland, events such as the America's Cup 2000 and 2003 and the Rugby World Cup 2011 have produced dramatic urban fringe development along the waterfront – will their legacies prove beneficial to Auckland? The reality is that event-led development has the potential to produce poorly distributed outcomes, chiefly because of the spatial specificity of the events themselves and the potential lack of valuable public participation due to the speed at which the project is implemented (Coakley and Souza, 2013).

It is argued that such development is beginning to overwrite the history of the waterfront space in the same manner as European occupation and development was stamped on top of aboriginal Māori history in the study area. It is argued that a detailed morphological reading of the space, concerned only with the building form, fabric and ground plan, has the potential to dismiss the erased history of a site and render it invisible. To this end a consideration of colonial modification to the unmodified waterfront is included. As redevelopment takes place, particularly in locations where societies do not have a built form legacy, what is the effect on the history of that space?

Methodology

A morphological analysis of the evolving and existing Auckland waterfront study area is undertaken. Historical land use maps, photographs and newspapers have been consulted alongside literature and the authors' own observations of the present day Auckland waterfront to produce an analysis of plan units on the Auckland waterfront. Plan units are mapped spatially in order to group land use and built form along the waterfront. Plan unit diagrams have been constructed which show the Auckland waterfront at three intervals: 1840 (none due to the nature of Māori occupation); 1939 (eight); and 2014 (twelve).

Auckland

Auckland is a city of 1.4 million in a country of 4 million. Auckland's economic prosperity has been linked both publically and in reality to recent investment in the waterfront area. After unifying district and regional councils in 2010, Auckland Council created the Auckland Waterfront Agency to oversee the further development of the space, recognising the economic importance of waterfront redevelopment.

Initial colonial development (including vast reclamation schemes in the Waitemata harbour) was driven by the economic stimulus of the marine and shipping industries. In contrast, present development on the waterfront is conceived as primarily driven by the economic stimulus of international events hosted in Auckland. Just as the colonial reclamation of the 19th and 20th centuries ousted Māori land use patterns, modern redevelopment is alienating the morphological patterns of marine and shipping industry. As a result, Auckland is experiencing redevelopment aimed at creating a consumer waterfront for international tourism and the elite residential market that is in the process of erasing the morphological history of the study site.

Pre-European contact Māori occupation

Pre-European contact tribal occupation within the Auckland isthmus has been fluid since the Māori people first landed in New Zealand some 1000 years ago. Most recent rights of *ahi ka* (traditional occupation) are held by the Ngati Whatua iwi (tribe). Ngati Whatua operated farming, horticulture and fishing operations about the entire isthmus pre-European contact (Ngati Whatua o Orakei Maori Trust Board 2003). The tribe was denied access to the land and so cut off from their cultural practices. This had profound impacts on the people of Ngati Whatua as their culture derived *mana* (respect and authority) from their role as *kaitiakitanga* (resource guardians). The ensuing reclamations in the Waitemata harbour engulfed landmarks of cultural importance to the Māori people such as Te Ngahuwera Pa (a military fortification) at the foot of present day Queen Street and Te Rerenga Ora Iti at the site of present day Britomart, where a great military victory was won over rival tribes (Auckland City Council 2004).

In 1840 Te Kawau of Ngati Whatua made 3,000 acres available to Governor Hobson in order to strengthen ties between the government and his people following the signing of the Treaty of Waitangi (New Zealand's founding document) (Ward 1999). He believed the two peoples would live together in this land. The area contained the 1840 waterfront and central business district, upon which the reclaimed present-day waterfront situated. Upon securing a new location for his capital, Governor Hobson immediately began development of the waterfront so that it be made fit for European occupation.

Figure 1 shows the shoreline as at 1840, prior to modification. The modern waterfront ground plan is also shown. The difference between the two is striking. Colonial occupation and modification of the Auckland waterfront, Auckland treaty settlements, is a matter for others (see Durie, 1998; Ward 1999). From a morphological perspective, as at 1840, there were no plan units recognisable by the Conzenian analysis of built form, urban fabric or plot size. This is precisely because the Māori culture did not build in this manner nor recognise an individual ownership model. For these reasons, the Conzenian morphological regionalisation approach is an incomplete method of capturing a comprehensive understanding of the history of urban form development. This is an important caveat to the method and is all the more noticeable in a location such as Auckland with such a limited history of European occupation as opposed to the long urban histories of England where Conzen developed his thinking (Conzen, M.R.G. & Conzen M.P. eds, 2004).

The development of natural and physical effect can have a deleterious effect on the link between cultural heritage and living cultural expressions of status and authority. Colonial industry development on the Auckland waterfront established new expressions of the authority of a new culture in place of the existing aboriginal Māori occupation. Land uses (fishing and

port activity), as well as landmarks, were erased by colonial modification. For instance, the mining of Point Britomart demolished the significance of the place for Māori. The British flag was first raised on this landmass on 16 September 1840 after a preliminary agreement for the sale of Auckland had been signed (McClure, 2012). It represented an important landmark in Maori history and geography, by the turn of the 20th century it was gone. The colonial experience dominated indigenous culture both socially and physically through how they built their city. It is likely that an invisible indigenous culture in the city morphology is an unconscious by-product of the way colonisation occurs through active oppression of that culture.

Figure 1. pre-1840 Auckland Waterfront Plan Units (zero).

The reading presented here contributes to the invisibility of the Māori population to a modern audience. Colonial powers have successfully rewritten the history of the space by inscribing new meaning through urban form. This inscription can be primarily expressed through a modification of the waterfront edge itself via reclamation for new land use. Colonial occupation through modification of the shoreline and private land titles represents the original privatisation of the waterfront. Recent residential and commercial development is arguably having the same effect by replacing the presence of the Auckland Harbour Board and POAL on the waterfront with elitist apartments and hotels.

Colonial reclamation and waterfront modification

Extensive reclamations began almost immediately following Hobson's decision to move the capital from the Bay of Islands (to the Auckland site Te Kawau made available) (Ward, 1999). The move yielded positive economic results for the new city. The deep Auckland harbour was an ideal port location and successive dredge and fill techniques both deepened the harbour and brought the wharves and associated land to the deeper waters.

Reclamations began with provincial government land tips pre 1859 and continued in force throughout the 20th century (Engineer's Department Auckland Harbour Board 1973). The most active period of reclamation was 1910-1916 in accordance with the Hamer scheme (Engineer's Department Auckland Harbour Board 1973). The waterfront still contains many examples of wharf buildings constructed in the Edwardian and classical revival styles including the ferry terminal, wharf police, post office. Each are examples of reclaimed land that has been vested in public ownership for public works, characteristic of fringe belts.

The reclamations from 1840 onwards dramatically altered the shoreline of the Auckland isthmus. Figure 2 shows the progressive reclamations from 1859-1972. The original shoreline and its associated activities were erased by this new morphology in just 170 years. Landfill cut

off headlands and filled in gullies to create a flat waterfront conducive to port and transport activities, thus fulfilling the role of CBD support common of fringe belts: the Māori occupation of this land left no trace that could endure the colonial reclamation modifications.

Figure 2. Reclamation on Auckland's waterfront 1840-1972 (Constructed by author from Auckland City Council, 2014).

Plan units have been identified using a 1939 land use map in Auckland City Archives. These are shown in figure 3. Attention should be focused on the large port (8) and Wynyard Quarter (1) units at the East and West ends of the waterfront as well as the viaduct harbour unit (3). All three locations are dramatically different in modern times. In 1939 they were examples of vast expanses of marine and shipping industry land use; today these activities are dramatically smaller, with new higher density developments on surplus land.

Figure 3. Planning units on Auckland's waterfront 1939.

Table 1. Plan units

Plan Unit	Unifying characteristics
1. Wynyard marine industry unit	Marine industrial land use: large plots on reclaimed land. High impervious surface percentage and an absence of vegetation. Vast clusters of chemical tanks dominate the land use.
2. Victoria Park unit	Large singular plot: reclaimed public open space, bordered by streets on all sides.
3. Viaduct Harbour unit	Dilapidated marine industry site.
4. Viaduct public facilities unit	Community pools and City market; large, public buildings.
5. Central area unit	Medium-rise commercial buildings forming the waterfront border of the CBD.
6. Transport unit	Auckland station; Edwardian terminal.
7. Ferry transport unit	Edwardian-baroque ferry terminal, nestled inside port land use.
8. Port unit	Extremely large plot size accommodating many storage sheds for port use.

Colonial occupation established new land uses across the isthmus and in particular along the waterfront. Headlands and gullies became shipping yards fit for port activities. Not only was the physical landscape changing but the political as well. A colonial governmentality was imposed a “colonial-based articulation of power” in New Zealand (Certoma 2013, 9). Maori lost the opportunity to engage in power relationships, to resist and to have real impact on planning matters. British Parliament passed the New Zealand Constitution Act (1852) which conceded administration of all matter relating to land to European settlers. New Zealand parliament was established without iwi representation because only men with claim to land with a single title could vote and participate. Iwi power was revoked and Maori were removed from the planning sphere in one clean stroke. The New Zealand parliament defined a new planning reality that permitted no meaningful opposition.

The newly established New Zealand parliament recognised individual title only: land sales were transfers of the right to exclusive possession. Prior to European occupation land ownership was tribal and ongoing (Blair 2002). This is an expression of Flyvberg’s proposition that power defines reality (1998). In real terms, the *definition* of land ownership asserted and defended by the British-based legal system facilitated a grave asymmetry between the settlers and Maori. Backed by the power of knowledge creation and the ability to legitimise their definition, the settlers created a new planning reality for Maori in New Zealand that they could not engage in

effectively. As a result, Ngati Whatua iwi experienced a 82,000 acre land loss. Without their turangawaewae (home place) the cultural, spiritual, economic, social and environmental wellbeing of the tribe was destroyed.

Modern Auckland

The Auckland waterfront stands in contrast to the geometric uniformity of the central business area and clearly encloses the expansion of the central city. It is an area of low-lying reclaimed land protruding into the Waitemata harbour, characterised by sweeping roads which previously followed the coastline and jutting finger wharves built for the shipping industry.

Alienation occurs within the fringe belt as redevelopment of land constitutes a move from historic land use towards smaller, privatised uses. In Auckland the Viaduct Harbour, developed for the 2000 defence of the America's Cup, and the Princes Wharf are examples of fringe belt alienation. Previously sites of marine industry, both sites have been transformed into high-density residential and commercial properties. These conversions largely ignore historical land use characteristics, and therefore epitomise alienation.

On the Auckland waterfront the authors find the following plan units shown in figure 4. The delineation used is largely based on the analysis found in Gu 2013 however some plan units have been added. These are the division of Wynyard point into two units (Wynyard marine industry and Wynyard quarter units) so as to reflect recent developments of the Wynyard quarter including North Wharf restaurant area and innovation centre. The Viaduct Harbour unit presented in Gu 2013 has also been redefined as two units (Viaduct harbour and Viaduct commercial). The multitude of plan units present on the modern Auckland waterfront speaks to the difficulty in presenting a coherent whole.

Figure 4. Planning units on Auckland's waterfront 2014.

Upon comparing the plan units of 2014 in figure 4 with those in figures 3 and 1, it is immediately clear that the number of units along the waterfront has increased over time. This speaks to the fragmentation and alienation of the space in that there are many planning units and this hinders cohesive development. In recent years units 2, 4, 6 and 10 have been heavily invested in and have undergone substantial redevelopment. Units 4 and 6 (Viaduct Harbour and Princes wharf) have done so as a direct result of international events preparation. In particular contrast to the 1939 image shown, the open space near viaduct has been built up into elitist apartment dwellings.

Table 2. Plan units

Plan Unit	Unifying characteristics
1. Wynyard marine industry unit	Marine industrial land use: large plots on reclaimed land. High impervious surface percentage and an absence of vegetation. Low-rise commercial buildings organised in a through street pattern.
2. Wynyard quarter unit	Auckland's recently successful public waterfront space. Low-rise commercial buildings and medium-sized public open space connected along a pedestrian route.
3. Victoria Park unit	Large singular plot: reclaimed public open space, bordered by streets on all sides.
4. Viaduct Harbour unit	Heavily redeveloped in the 1990s, this residential area consists of much smaller parcels than the historic marine land use previously located here. Irregular through streets. There is a strong coherence of built form across the space, which consists of mid-rise modern residential buildings.
5. Viaduct commercial unit	Prominent mid-rise commercial land use around a major regional transport route. Poor pedestrian infrastructure.
6. Princes Wharf unit	A high-density hotel development privatises the wharf space and alienates it from the fringe belt. Built form resembles a cruise ship, which references the maritime legacy of the harbour.
7. Central area unit	Large lot sizes occupied by high-density, high-rise structures. A six-lane street dominates the street level.
8. Ferry transport unit	Edwardian-baroque ferry terminal (restored in the 1980s) alongside modern additions to the capacity of the transport terminal.
9. Queens wharf unit	Currently occupied by temporary structures, the land is now surplus to port requirements. The space is still fronted by the historic (and protected) red wharf fence, deterring public use.
10. Britomart transport unit	Grid street layout: The area is a commercial and transport hub developed in response to regional transport strategy. Northern edge fronted by historic wharf buildings including the wharf police, northern steamship and union fish company buildings.
11. Port unit	Large singular plot: expansive private open space, used exclusively for port activities. The area is fenced off to the public but offers a glimpse into the working waterfront of Auckland. This large area bordered by a major regional transport corridor.
12. Quay park unit	Medium sized irregular plots: this area is largely of mixed modern design, including both residential and commercial land use. Irregular, curving streets throughout.

The Modern Auckland waterfront is undeniably the result of land release by Ports of Auckland. Most notably, the focus of port operations have shifted Eastwards in the last 20 years and have made the Viaduct harbour and surrounding land as well as Princes wharf available. Between 1989 and 2013 72 hectares of waterfront land has been released from the Port of Auckland, allowing space for future event-led development (Ports of Auckland, 2013a). Present day port operations now occupy approximately half the land area of the waterfront.

Princes wharf, now the site of the Hilton Hotel, is one example of land release and subsequent fringe belt alienation along the waterfront. Princes wharf sold for NZ\$25.75 million in 1997 and the Hilton Hotel built on it promptly to take advantage of the international tourists associated with large events. The development is a controversial one in light of private appropriation of the prominent waterfront location. The public street that previously ran the length of the wharf now operates as a car park for hotel guests and taxis.

The poor planning outcomes on Princes wharf were the direct result of the fragmentation of District and Regional councils in Auckland. In 1988 the Auckland Regional Council dealt with the application since it was on water, not land. This meant that the Auckland District Council isthmus plan had no jurisdiction, despite the building clearly having urban design and traffic implications (Cayford, 2009). Because district planning issues did not need to be addressed, the development proceeded without public consultation in 1998. The result was a poor planning outcome for the public and a privatised, alienated section of the fringe belt without opposition from the public.

The reduction of port operations as a stimuli for redevelopment is a common reality for many urban waterfronts such as London, Melbourne and Boston (Gordon, 1996). In Auckland another element was in the mix: international events were coming to Auckland like never before.

The history of event-led development in Auckland began as early as the late 1980s when New Zealand's yacht team 'Team New Zealand' seemed poised to bring the America's Cup home in 1989. The event had real impact on the political climate of planning process in New Zealand. At this time Mike Moore, a newly created Minister for America's Cup, pushed for an America's Cup planning bill that would speed planning applications. The position and planning reform was deemed appropriate in light of the potential for international tourists coming to a future America's Cup defence. The 1992-93 Whitbread round the world ocean race was also recognised as a stimulus for tourists; the event would bring 800,000 people to the Viaduct (Basset, 2014).

However the new planning bill and Minister were not needed as the Team NZ did not come away with the 1989 win. And so, apart from some dredging for the Whitbread race, the Viaduct remained unchanged when Team NZ did eventually lift the America's Cup in San Diego in May 1995. By August Auckland Council had authorised a development committee following submissions by eager developers. Pacific Development Investment Corporation suggested commercial and residential space and further dredging in the Viaduct harbour (Basset, 2014). The fringe belt was poised for the alienation process.

As noted in the introduction, event-led development has the capacity to produce poor planning outcomes chiefly because those outcomes are geographically concentrated expressions of public investment. Investment that is derived from the wider rates base both locally and nationally. In New Zealand, sport events have become synonymous with national pride and with notions of healthy communities, making plans for their propagation extremely difficult to argue against. Public opinion can so easily swayed when plans are justified by national sporting pride (Hall, 2006). This reality allows politicians to capitalise on planning contributions that will make their city more globally competitive, despite the fact that these outcomes are concentrated spatially and economically as was the case with the Viaduct development (Hall, 2006). The uneven spatial distribution of development within a city and can further entrench the power of the elites (Jones, 2001).

The Viaduct harbour is one example of spatial concentration of planning outcomes as a result of event-led development in Auckland. In 1996 Viaduct Harbour Holdings Ltd. bought the Viaduct and its surrounds from POAL for NZ\$75 million. The land had been for sale since 1995 as POAL shifted East. In 1998 stormwater and wastewater were realigned and the harbour widened and deepened so as to improve the water quality. It's important here to note that the port activities, the fringe belt, restricted the growth of the CBD up until its removal. As sections such as the Viaduct were sold, residential and commercial land uses encroached upon the fringe belt and alienated the Viaduct Harbour from their historical uses. Figure 5 and 6 show the

viaduct harbour in 1940 and today. The comparison is a dramatic example of waterfront redevelopment, with cast harbour land reclamation occupied by medium-rise residential and commercial buildings eliminating the historic marine industry land uses of the area.

Figure 5. Auckland's Viaduct Harbour 1939.

Figure 6. Auckland's Viaduct Harbour 2014.

In 1999 Auckland hosted the successful defence of the America's Cup. This was an economic benefit to Auckland like none before it and signalled enormous economic activity, injected into waterfront redevelopment. The net expenditure of the America's Cup 2000, according to Market economics, was \$474 million with a total value of \$640 million added to the New Zealand economy. This event created the equivalent of 10,620 full time jobs.

In 2003 Auckland hosted the America's Cup again and generated, according to Market Economics, a total of \$523 million net expenditure and the equivalent of 9,320 full time jobs between 2000-2003 (Market economic Ltd, 2003). Most of the impact was in the 2002-2003 year. The majority (70-85%) of the economic impacts of both yachting events were concentrated in the Auckland region due to the restricted spatiality of the event. The legacy of America's Cup is its boost to the New Zealand's marine industry, which is now worth NZD\$1.7 billion; the sector NZD\$642 million had worth of exports in the year 2012 (Forbes, 2013).

In 2005 New Zealand was selected to host the 2011 RWC. In 2008 Auckland Council pledged NZ\$211 million to the redevelopment of the Wynyard quarter and a further NZ\$88 million by 2010 in preparation for the event (IRB.com 2011). The Queens wharf sheds were

redeveloped and the 'Cloud' installed to allow the public screenings of the games and host events on the waterfront. The RWC2011 resulted in \$512 million additional expenditure in Auckland across the period between 2006 and 2012, split amongst property, construction, manufacturing, transport, storage, finance and communications (IRB.com 2011). The New Zealand Economy grew by \$573 million as a result of additional expenditure during the Rugby World Cup, and the tournament sustained 22,890 jobs for the duration of one year (Ministry of Business, Innovation and Employment, 2012).

These figures show that international events represent large injections of overseas capital to the country and are thus desired by local and national authorities. The economic stimulus has become the driving force of urban renewal just as port activity once served as a driver for modification to the pre-European occupation shoreline. Investments in international events during this period reflect council philosophy. Auckland Mayor Len Brown is quoted as claiming that "events should be the drivers of economic growth and they have certainly delivered for Auckland" (RWC 2015, 2012). Events-led development has strong positive connotations in Auckland as a result: "it has only been a few months since Auckland was the hub of Rugby World Cup 2011, but our region has been transformed forever" – Doug McKay (Auckland Council, 2011, pg i). Ultimately Auckland's City Council and tourism agencies are trying to achieve economic growth through these events. This pursuit of growth through events shapes the pattern of urban development as they become integrated into the strategies of urban renewal (Hall 2006).

These events illustrate the optimism for new development that international events can stimulate. Particularly in areas of public space such as waterfronts. We saw this excitement again in 2013 when Team NZ seemed assured of victory in San Francisco, spending much of the regatta with only one point needed for victory. Planners and politicians alike were teeming with excitement for new developments in Auckland. As the nation watched the victory slowly slip from Team NZ's grasp, planners felt the very real blow to future development.

Conclusion

Historical land use maps, photographs and newspapers and the authors' own observations have produced an analysis of plan units on the Auckland waterfront. Plan unit diagrams have been constructed which show the Auckland waterfront at three intervals: 1840 (none due to the nature of Māori occupation); 1939 (eight); and 2014 (twelve).

This research paper demonstrates that Auckland's pre-European occupation shoreline has undergone two broad eras of modification. The first being the colonial reclamation of the waterfront to accommodate port activities. This resulted in the filling and levelling of valleys and streams outside the heart of the newly establish Auckland CBD. Plot sizes were large and housed public and industrial land use, which is common for fringe belt zones in the city (Whitehand, 1988; Gu, 2010). The second era of waterfront modification began with the reduction of port activity along the industrial waterfront in the 1990s. This period signalled the densification of the working waterfront recognisable as a process termed alienation. This most recent period of modification, which has brought residential and commercial land use to the fringe belt, has been driven in part by an eagerness to make Auckland ready for international events including the America's Cup 2000 and 2003, Whitbread round the world ocean race and Rugby World Cup 2011.

It is postulated that the first broad period of development, that being the colonial modification of the waterfront driven by the economic reality of port orientated city. Urban form constructed during this time has left visible marks on the urban landscape that may be read by an analysis using the Conzenian morphological regionalisation. These are the built form (where it survives), plot sizes and street layouts. Contrastingly, this visible legacy is not found for the Māori occupation of this area prior to 1840. Māori used the waterfront and indeed the wider isthmus to practice fishing, horticulture and farming. The landscape was inscribed with a cultural history

that was retained orally and not in the edifices of urban form. Thus, once the landscape itself was completely modified beyond recognition and a completely new ownership model established, Māori history was erased.

The second period of urban development within the study site has been shown to be in part driven by the economic stimulus of international events held in Auckland. This period of development is really one of *redevelopment* in that the existing legacy of colonial modification, as we have termed it, is present. This fringe belt legacy informs modern construction of urban form along the waterfront. Primarily through the release of port land for residential and commercial densification. Land that is of a large plot size and open space.

Event-led development itself has its positive and negative implications. Event-led urban development has a focus on infrastructure for people with improvements around public transport and public space. It can be a serious driver of short to medium term economic improvements with increases in jobs and tourist expenditure. Events-led development can provide certainty for urban development, through local and national investment programs, allowing significant investment in infrastructure. This was demonstrated in the case of the NZ\$211 million investment in infrastructure for the Rugby World Cup in 2008 from the Auckland Council. This investment is less likely to occur if there is no event to leverage against financial costs.

Due to spatiality of events infrastructure, event-led development has the potential to eliminate connections between planning units and fragment existing units as select areas are developed. For example, in response to the America's Cup 2000 and 2003 and the Rugby World Cup, only select areas of Auckland's waterfront underwent development. These were the Viaduct and Princes wharves. As was the case in Auckland, when development is staged over time in correlation with numerous events, there can be a lack of continuity and cohesion between planning outcomes, which make up the modern plan units on the waterfront. In Auckland this is best expressed by the low pedestrian permeability of the waterfront space as a whole; and the lack of cohesion between plan units 4, 7 and 2 in particular. The resulting waterfront is a difficult one to navigate for a pedestrian. The task is made all the more imposing because the public space is bordered by the exclusive Viaduct and Princes wharf developments which encroach onto the public pathway and contribute to a feeling that the public user does not belong. A better understanding of the existing plan units could contribute to a more holistic conceptualisation of the space and the connections between units. The Royal Commission on Auckland Governance 2009 expresses this view and bemoans the lack of coherent management and development of the waterfront space. The report recommends a master plan approach to the waterfront and city centre areas to enhance public and private investment in the area (Report of the Royal Commission, 2009).

Considerations for development in the future should consider the alienation process as a reinscribing of meaning onto the urban landscape. This definition has been proven apt in the example of Auckland's waterfront as 'Māori history' was replaced through waterfront modification to become 'colonial port history.' That history is now slowly succumbing to the new economic reality of event-led development, which brings with it new plot sizes, street layouts, urban form and levels of density.

To summarise, this paper has examined the Auckland waterfront using the lens of an urban morphological analysis grounded in an understanding of the fringe belt concept. Modern redevelopment along the waterfront is found to be erasing the 170-year history of colonial occupation and port reclamation in much the same way that the reclamation erased Māori land use in the area. However in contrast to the modifications of the 19th and early 20th centuries, modern redevelopment is intensifying land use within the layouts of the historical industrial waterfront and in doing contributing to the alienation of the fringe belt through private appropriation of public open space. Consequently, recent developments are establishing a new cultural authority over the space: that of international tourism associated with sporting events hosted in Auckland city. This raises questions of equity as to the land uses permitted and supported using public resources in the waterfront space.

If future planning and urban redevelopment takes place ignorant of the plan unit concept, there is potential for future development to overwrite the history of the waterfront, create disconnected plan units and dominate potentially important public spaces without a recognition of its past land use. However this paper has shown that there are limitations to this solely morphological understanding of urban space in that the history contained within a plan unit analysis can omit invisible cultures such as Māori occupation in this example.

Abstract. *The evolution of the urban form has always been affected by numerous factors. This article aims to discern to what extent the governing schools of thought have determined the form of the cities. From the emergence of Islam to the contemporary period and before the start of information age, we have categorized three distinctive systems of thought: Islamic approach, the colonial period often with a modernist essence and the contemporary period (mainly after the independence of the country and bearing upon modernist and post-modernist views). Each of these systems has affected the form of the city in general and also its components. Studies in Tehran, Damascus and Cairo indicate that in the Islamic period the changes made to the form are mostly limited to single buildings contributing to emphasizing the presence of Islam in the city or as a manifest to the power of the caliph, however the general form of the city has mainly stayed untouched in compliance with the local social and environmental requirements. In contrast, the colonial period is coupled with vast changes and modification to both the general form and its components due to the technological advances and the mass production trends. The changes in the contemporary period are however built upon the challenges that the modernist approach brought about and therefore take a more moderate route.*

Key Words: *Urban form, governing schools of thought, Islam, colonial period, modernism, post-modernism*

Introduction

For most researchers in urban morphology urban form mean the form of urban fabrics (Levy, 1999). However urban morphology is also used as a source of ideas about spatial elements which can be used in the construction of proximal spatial models of cities (O'Sullivan, 2000).

This article aims to assess the effect of one dimension of the socio-political aspect of the city on its form, namely the governing thoughts. In order to avoid generalization three cities were chosen for this purpose; Damascus, Cairo and Tehran based on the similarities of their history. There is of course much to be discussed about what the term governing thoughts entails and how it can be categorized, however the authors have discerned four main periods in the history of the mentioned cities: emergence, Islamic period, colonial period and contemporary period. These periods sometime overlap as for instance the emergence takes place in the Islamic period and sometimes a city does not go through all the periods as is the case of Tehran which does not have a clearly defined colonial period, although its form has been influenced by its allies at the time.

As this article seeks to compare the form of city and its elements in the mentioned periods, it does not research the cause of the events of each period in depth and focuses more on the differences and similarities of the changes in different eras in target cities. In order to so first a brief description of what aspects of urban form is being studied and the different periods is given. Then the changes the cities go through in each period are introduced and finally there is a concluding comparison between the effects of each governing thought on the form of these three cities.

Urban form

The definitions of urban form vary to a great extent in the literature. While some authors solely rely on land use/land cover to measure urban form in terms of the physical structure of a city, others also include socioeconomic aspects such as population number or density. Furthermore, the question of whether the sheer size of a city is one aspect of urban form or an independent indicator is still open. However, urban form itself is mainly referred to as a property of a city and therefore static for a given point in time, while urban growth is a dynamic process that alters urban form. (Schwarz, 2010)

Urban form, or urban structure, refers to the land use patterns, transport infrastructure, water and energy infrastructure, and physical form of developments that facilitate human activities and their interactions. It is a product of the social and economic activity patterns of the city, its culture and its technology and is the outcome of physical planning practices, both in infrastructure development and in regulation.

Urban form reveals the relationship between a single city and its rural hinterland as well as the impact of human actions on the environment within and around a city. This also relates to transportation patterns (Schwarz, 2010).

Considering what was mentioned this article mainly focuses on two aspect of urban form in its research; the urban fabric, also referred to general form consisting of streets, infrastructure structure and etc, and also architectural elements and components.

Certain periods of time can be discerned in target cities regarding the governing thoughts. Regardless of how Cairo, Damascus and Tehran emerged, they have gone through different periods such as Islamic, colonial and modern periods. Like any other macro-scale change in the socio-political dynamics of a place, Islam also sought to announce its presence through various means in cities. Since Islam is considered to be an “Urban Religion which favors communal practice...it is widely accepted that most of Islam’s teachings are best practiced in an urban setting. It is not surprising that Islam made particular emphasis on the form and design of the city ... (Saoud, 2002)”

Besides the Islamic period most of the cities have also gone through a colonial phase which has vastly affected them, not only in terms of physical conditions but also cultural, social and etc. This period can be a somewhat clear example of how far an outsider system of thought would go to dictate changes in the context it is now governing.

There is also a time period in which the cities have declared independence or are being governed with a more modernistic school of thought which “was evident in the city’s physical appearance through what is called standardization of urban systems, as the width of roads, heights of buildings, zoning and segregation of use and etc (Abou El-Ela, 2003)”.

Currently the new communication system and the use of (ICTs) have increased the capacity to absorb all kinds of cultural, social and political articulation, in a digital globe that is electronically communicated and managed. They are modifying all aspects of the life of cities, political, economic and cultural and consequently affect the urban form as well (Abou El-Ela, 2003). Although these changes can be categorized as another period of a governing thought in cities, this research does not focus on this era.

Survey

Damascus - Emergence

The history of the Damascus is defined by usage of water. The original oasis was a central meeting point and a sustainable settlement which through time became the longest permanently inhabited city. The initial structure of the city as one of Aramaneans governing centers was formed in 11 century BC and had a western feel to it. In the year 46 BC Romans occupied the city and an orthogonal settlement was formed near the Aramanean city with straight streets,

forum, stadium and Hellenistic residential areas. Romans built a fort around the Aramanean and Hellenistic neighborhoods. After the Byzantine empire, Arabs entered the city in 635 AD (Coeno, 2003), (Chang & Lienert, The Oasis City, 2009)

Figure 1. Hellenistic Damascus (Burns, 2011).

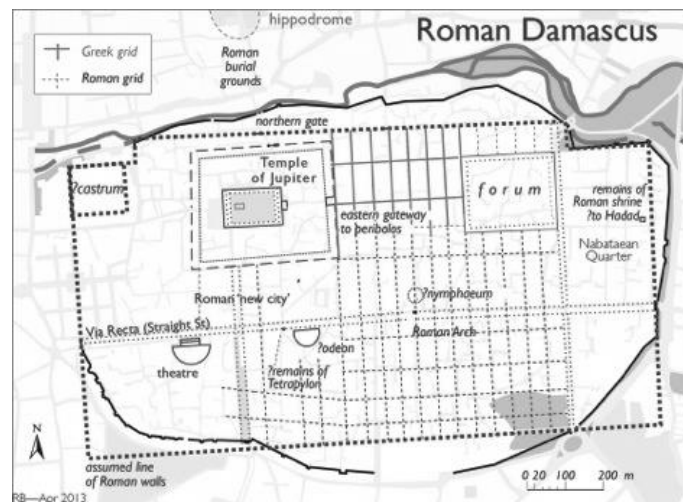

Figure 2. Roman Damascus (Burns, 2011).

Islamic period

Damascus had become mainly a settlement for the wealthy Arabs and the Umayyad Caliphate decided to build a mosque for all the Muslims of the world. Such a building required significant financial power along with exceptional design and organization so the Caliphate invited architects from Syria, Byzantine, Iran and Constantinople. The walls of the mosque illustrated utopian cities and gardens (Coeno, 2003) In the “Everyday life of Damascenes” the neighbors are described to have close relations and shared interests and ceremonies in the Islamic period. The shop owners would control the presence of strangers in the neighborhood. The narrow and winding alleys would preserve women from the eyes of strangers (Ghazaf, 1988).

But how did the Arabs, who were converted to Islam, apply the concepts in establishing new settlements and in adapting existing towns and cities, such as the case of Damascus. The organic

Islamic city began in the Byzantine Empire. The Greek and Roman city followed strong geometric patterns and straight lines (Wifstrand, 2009). Therefore the street network in the older parts of the city is based on the canals built by Aramaneans, Semitic nomads from Mesopotamia, and also based on later orthogonal network of Romans and Umayyads.

Figure 3. Street network in the old part of Damascus (Wild & Stokhammer, 2009).

The strong ritualized living patterns of Islam made formal institutions unnecessary and so open spaces like forum disappeared over time. This transformation from straight Roman street grid with large open spaces into Islamic narrow street-cities happened slowly taking many centuries to form.

The entrance of Arabs is not associated with drastic changes in the form of the city and the changes are limited to the construction of a mosque and a palace for the Caliphate. However after the city became the capital of the Umayyads, gradually other public centers were formed near the primary establishments: Judiciary building, entertainment center, stables, numerous bazaars and indoor trade complex for valuable goods. But the growth of the city took place in accordance with the historic water distribution system (Coeno, 2003).

Colonial period

With the introduction of pipelines through The French, the old system of the canals and sabils was not needed anymore therefore the streets which were formed based on the placement of canals could also be changed. The result of these changes in one of the western neighborhoods of the city can be seen in figure 4.

The last 60 years of the Ottoman Empire was a time of administrated reform and modernization, influenced by Europe. The new urbanism and this was before any French mandate master plan, that developed was based on three principles. (i) Widening of streets and roads. (ii) The design of new suburbs with geometric patterns. (iii) Construct in stone instead of wood (Wifstrand, 2009).

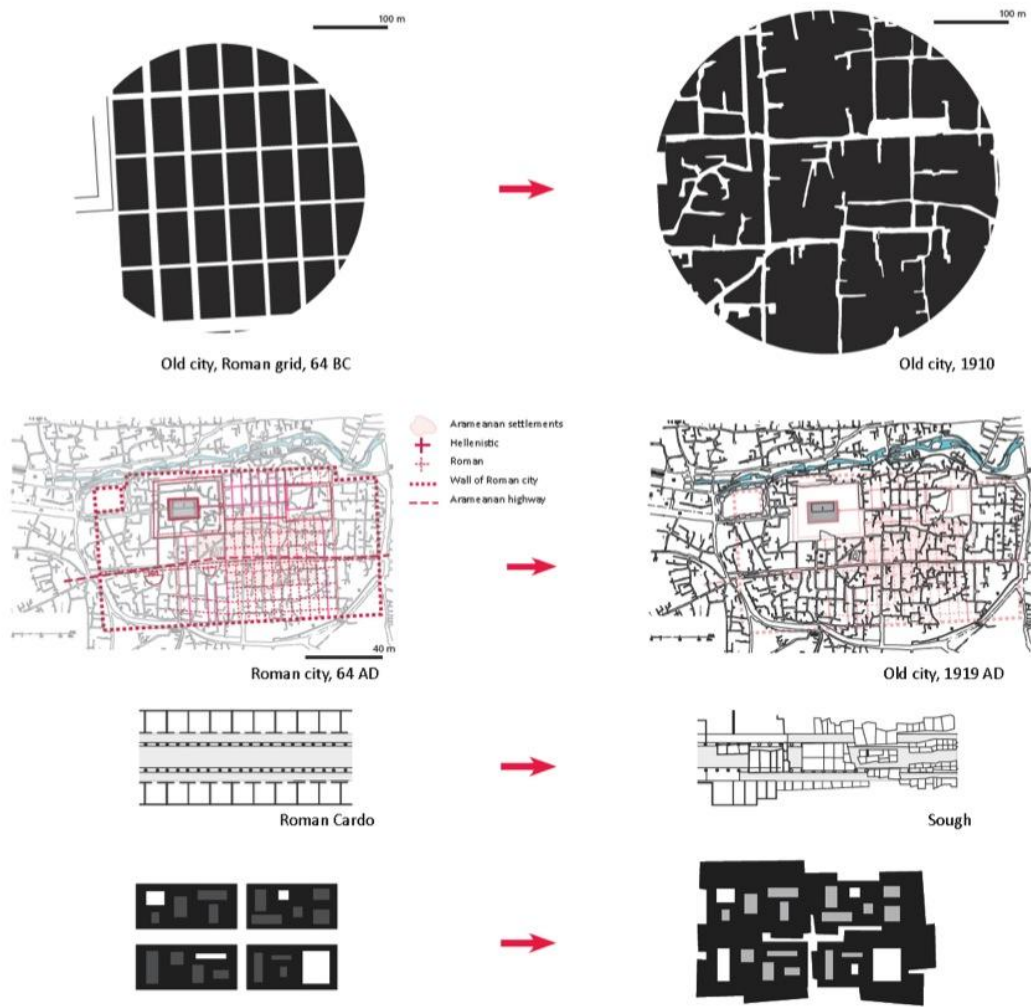

Figure 4. Morphological evolution from the Roman city to Islamic city in Damascus (Wifstrand, 2009).

Figure 5. Area of Baghdad Street in Damascus, Designed by the French (Wild & Stokhammer, 2009).

Another point which affected the form of the cities especially in the old city was the outward movement of wealthier population to modern suburbs and abandonment of old city. This exodus from the old city left it to be inhabited by the poor and in neglect (Wifstrand, 2009).

French Mandate continued the urban development which the Ottomans started in the 19th century. The first master plan for Damascus totally ignoring the local tradition and neglecting the old city, faced a lot of resistance from a city which has grown organically for a thousand years. Danger and Ecochard presented a new road system, creating a ring road around the old town to ease congestion but also to “show off” the cultural heritage of the old city (Wifstrand, 2009).

Figure 6. First French master plan for Damascus and surroundings: the Danger plan developed between 1925 and 1937. A recognizable grid shows the first French urban interventions (Wild & Stokhammer, 2009).

Architectural components of form

One of the important monuments of the city is the Umayyad mosque. The French proposed a plan to separate this mosque from the urban fabric in 1984 in which there is a road for vehicles around the mosque.

All architectural interfaces as the smallest piece of an urban fabric are very much part of the development of Middle Eastern city, especially Damascus. The smallest elements like the fountain, the tale' or the canals are influencing and determining the whole city structure. From the roman orthogonal canal grid to the hamams as urban nodes, the sabils as public meeting points and representative architectural elements to the courtyard fountain as the end of a whole chain of division and separation processes. The fountain again is defining the size of a courtyard and so also the proportion of a house, which is part of the urban fabric of a neighborhood and the whole city. All these elements formed urban fabric and are only working by a system of ancient pipelines and the natural gravity. The symbolic meaning of water is also given, because there is a strong bonding between architecture and infrastructure which is not separable because none of it is possible to exist without the other one (Chang & Lienert, The Oasis City, 2009). Although sabils have now lost their original function with the use of a modern water distribution system, there has been attempts in some parts to preserve them from an urban heritage viewpoint.

It can be assumed that most of the city parts developed out of a canal grid. So at the urban fabric of the city the history is still visible. The agricultural field which is strongly connected to traditions and heritage could also use the water of these canals. The original field was probably a square or rectangle and was in possession of one farmer. The ownership allowed him to use the canal with a certain amount of water for a specific time during the week. In every village or

city-neighborhood was a person in charge of the time schedule (Chang & Lienert, *The Oasis City*, 2009).

Figure 7. Water-related architectural components in old Damascus (Sabils, Fountains, Water reserves, orthogonal grids, etc).

Often buildings were built along main street, which was built along the main canal. So the canal had to be redirected around the building areas to the fields. Over time the fields got less important and the canals dried out or got abandoned and streets were built on top of it. A block structure evolved. The third step is that a total urbanization of the agricultural area happened. Most parts of the city were at a status of change. Only the main city and its areas around are completely evolved. Midan is an example for a perfect change from agriculture to a central urban neighborhood. Therefore between the 1870s and 1920s, it is assumed that irrigation system heavily influenced the urban morphology of Damascus (Chang & Lienert, *The Oasis City*, 2009). The following pictures illustrate this influence.

Figure 8. Water canals (simple line: Canals for the city, dotted line: canals for agricultural lands) (Chang & Lienert, *The Oasis City*, 2009).

Housing

Visible in the buildings of the French Mandate era is that the courtyard disappeared completely. The first time that it was possible to create apartments on one level, stacked onto each other. The building became a closed volume and the private exteriors changed from courtyard to balconies. The private exterior got minimized but there started to be a collective exterior in the form of public parks (Chang & Lienert, *The Oasis City*, 2009).

Gardens

A second step after decoupling of water from architecture was introducing a different understanding of gardens, coming along with the French mandate. The garden became something collective and shared a social meeting pot. It is something totally new in the understanding of public space in city, since the garden or also a “private exterior” used to always be clearly defined in terms of who it belonged to (Chang & Lienert, *The Oasis City*, 2009).

Figure 9. Pattern of modern (left) and traditional (right) houses in Damascus (Chang & Lienert, The Oasis City, 2009) (wifstrand & Jila, 2009).

Figure 10. Evolution of Gardens in Damascus (Chang & Lienert, The Oasis City, 2009).

In summary after the French came into the city, there was a change in the structure of the social and architectural life in the city. The main inventions and developments of the city which made Damascus the longest permanently inhabited city were made since the Neolithic era until 1920s. This period is of course very wide-spread but the infrastructure system did not change much in it. Canalization happened at the beginning of this period and then Romans connected the city with a pipe system to the spring water. Later on the Sabils were built in the city and generally there was a coupling of water and architecture. However after the installation of modern pipe system the decoupling of water from architecture started and continued by the French master plan by Ecochard which changed the cityscape from Damascus totally (Chang & Lienert, The Oasis City, 2009).

The main characteristics of this period can be categorized as follows: master plans, immigrations, socialism and neglect of the old city

Contemporary Period

In the contemporary period there is a selection of ideas which is mainly affecting the form of the city. Some of which include: garden city as a new take on the idea of an oasis set up in the desert, socialist city which targets mass housing as a strategy to move out the surplus inhabitants of Damascus, and gated communities which have mostly been formed for the more wealthy citizens but are changing the form of the city nonetheless.

Cairo

Islamic period

The emergence of Cairo occurs mainly with the entrance of Islam to the area which was consisted of disprsd settlements. The city of Fustat near the remains of Babylonian fortress was the first Muslim settlement. After that settlements as Al-Askar of the Abbasids and later Al Qatai of Ahmed and Tulun were built further north. In 969 the Shii'te Fatimid Caliphate conquered Egypt and developed a first plan (rectangular grid) for their city on a new site (Al-Qahira) (Mélanie & Nathalie , 2011).

In the early years Fatimid city was only a royal and military refuge city which had two palaces in its center. The main street was called Bayn al Qasrayn which means between the palaces. There was also a north to south corridor (Mélanie & Nathalie , 2011) & (Coeno, 2003).

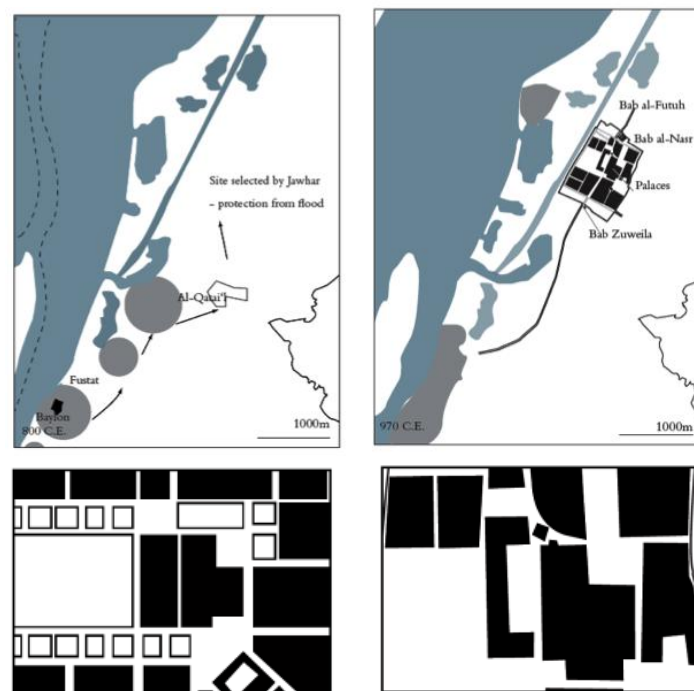

Figure 11. First Muslim Settlements (left), Fatimid Dynasty (right) (Mélanie & Nathalie , 2011).

As the Ayyubids came to power Salah-al-Din, principle ruler, built a gigantic wall encircling Fustat and Al-Qahira. He opened the former princely city to the public who began to build in its spaces and gardens, changing the function and structure of the Fatimid's city. The city then was consisted of very dense pattern of houses that formed narrow streets. Cairo developed from a military camp to a religious place. During the period of the Mamluks Cairo experienced a great growth. It was during al Nasir's reign that Cairo experienced its greatest

change and the western development was encouraged. Mamluks were famous for their wealth and ambitious building activity of madrasas, mosques, sabils etc (Mélanie & Nathalie , 2011).

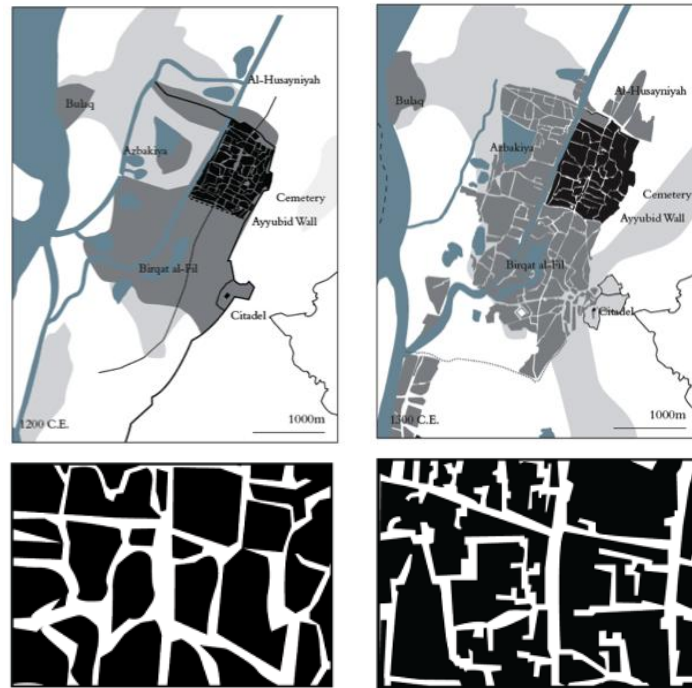

Figure 12. Ayyubid Dynasty (left) Mamluk Dynasty (right) (Mélanie & Nathalie , 2011).

Although there was many constructions in Ottoman period, the constructions were not very organized, monuments and open spaces were built in close proximity and densely especially in the old part of city, corridors were occupied by retailers who would block the traffic, and winding streets and unrelated and abnormal buildings cleared out the wide streets of the Fatimid (Coeno, 2003).

Figure 13. Ottoman Cairo (Mélanie & Nathalie , 2011).

Considering the changes in this period, the desire to integrate the architectural elements resulted from the local traditions with the capabilities and potential of a new context, is quite interesting. The loyalty to the local traditions which is manifested in the official buildings is evident (Raymond, 2002).

Colonial period

The modernization of Egypt and its capital began under Mehemet 'Ali (c. 1769–1849), often called the "father of modern Egypt," who ruled the country for nearly half a century beginning in 1805, modernizing and strengthening it, and expanding its borders. Modernization of Cairo began in 1830, but the period of greatest progress occurred during the reign of Ismail Pasha (r. 1863-79). Pasha undertook a major modernization of the city modeled on the renovation of Paris under Napoleon III (1808–1873). To the west of the older, medieval part of Cairo (now called Islamic Cairo); a newer section of the city boasted wide avenues laid out around circular plazas in the style of a European city. The development of this area was also influenced by the growth of French and British colonial power in Egypt (Cairo, 2008). The interventions went so far that the term “Paris along the Nile” is sometimes used to describe Cairo in those years.

Figure 14. Map of Cairo in colonial period (Elshahed, 2011).

Contemporary Period

Considering the significant growth of Cairo in recent years, new neighborhoods have formed and are being formed. Since the implementation of decentralization policies, the Islamic part of the city is declining. Although there are plans for conservation of heritage, the surrounding residential areas are mainly neglected. However there are bright planning spots as well, like the Al-Azhar Park.

During the 20th century the trend of restoring single monuments was converted into a new ideology. Many heritage and conservations plans were set for the city. But one can summarize that all the plans intended to create a monument corridor with touristic infrastructure that has the character of an open-air museum. There is no clear and specific building law for city parts which makes the development even more unpredictable and confusing.

Tehran

Emergence

Decline of Rey was the advent point of Tehran development. Rhythm of development of this city became faster in Saffavid Dynasty. When Ghazvin was chosen as capital, Tehran became subject of attention for authorities due to its good location and weather.

Figure 15. Current Cairo and the location of old city (Mélania & Nathalie , 2011).

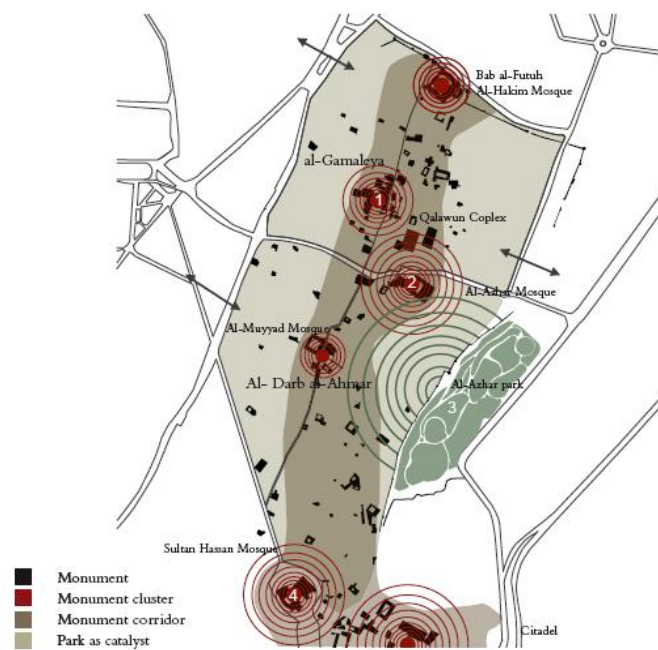

Figure 16. A sample of heritage and conservation plans (Mélania & Nathalie , 2011)

Figure 17. Rey and Tehran (Hamidi, 1997).

Islamic period (beginning of Ghajar dynasty to Nasereddin Shah)

In 1200 Mohammad Khan, king of Ghajar chose Tehran as capital of Iran. This new role of the city changed its form and landscape. However the changes in this period were limited to establishment of new buildings and walls and later on development of new communities and inner growth of market (Hamidi, 1997:19). Indeed, evolution of urban structure was the main change in the city during Mohammad Khan's reign.

The king after him, led the growth of city outwards by building mosques, markets, communities, palaces and gardens out of the city boundaries (Hamidi,1997:20). This approach was modeled after the changes in Paris regarding Versailles. Generally, at this stage development of the main structure adhered to linear-branch and linear- central patterns (Hamidi,1997:22).

Architectural elements of urban form including mosques, schools and formal and official buildings especially in new urban centers; have bigger lots and open spaces at this stage, but still adhere to introvert pattern. The texture is still continuous and integrated which conforms to the existing linear-branch pattern (Hamidi,1997:22).

Introduction of Modernism (from Naserddin Shah Ghajar to Islamic Revolution)

Vast urban growth occurred in Naserddin Shah Ghajar reign which was the second stage of development in Ghajar dynasty. In this period many new buildings and gardens were built in Tehran and the city expanded significantly. However main elements of urban form remained untouched.

Amirkabir was one of the men who had a major role in the development of Tehran. In this period compact and dense texture of the city, and narrow non-geometrical streets were regenerated (Hamidi, 1997: 24-28).

Although the city development occurred in all directions, the quality and quantity was not the same. The growth was more concentrated in the north of the city because of the location of king's palace.

Figure 18. Emergence of wide and semi-orthogonal streets in Tehran and concentration of growth in north (Hamidi,1997).

This period is characterized by gradual and integrated growth of the previous pattern which also in some places is starting to show the first steps towards the fundamental changes in the next period (Hamidi,1997:31).

The changes to the structure were mainly the result of the construction of new streets, squares and buildings which changes the nature of the structure from linear-central to a grid pattern. This new grid pattern could also accommodate new urban elements which subsequently further changed the form of the city.

Architectural and urban elements which were built in big plots were surrounded by great open spaces as well. Therefore the space-mass ratio shows a significant increase (Hamidi,1997:32). The wide streets and squares subsequently led the development of the structure towards the outer regions.

Another major change in this stage was the pattern of urban façades and monuments. For the first time great attention was paid to the design of exterior facades of the buildings and also the placement of monuments and signs. Shamsolmareh is a good example of this change.

Another indicator of visual characteristic of this period is the construction of important buildings specially Ghajar palaces in strategic topographical points outside the city. One of these examples was Doshan Tappeh palace. (Hamidi,1997:34-372).

Figure 19. Great open urban spaces and Ghajar palaces in strategic topographical points outside the city (Hamidi,1997).

Two sets of internal and external factors contributed to neoclassic or neo-traditional styles in Ghajar dynasty. The most important internal reason was Ghajar's tendency to associate themselves with the powerful Safavid dynasty. And one of the major external agents was the attempt to define a new identity for country in relation to the new world which was very important for the Ghajar government. This definition of identity led to total and fundamental change in urbanism and architecture. In this approach city was considered as a new interpretation of the old city with different time- space concepts (Habibi, 2004). The emergence of Tehran style occurred in this era but achieving the real concept of this style needed two historical event; 1-reformal practices of Amirkabir in creating new official systems and 2- presence of European teachers and engineers in Darolfonoon school as the first professional school in Iran (Habibi, 2004). Tehran style in general avoided interfering with the old parts of city but tried to changes some functions and elements which in some cases resulted in social movements, for example moving the city center from Sabzeh Meidan to Toopkhaneh square.

Pahlavi

This period was accompanied by changes of the main structure of the city in the official and legal frame of Baladiye (municipality). In which one of the first action was demolition and renewal of traditional old neighborhoods of city center. In addition construction of wide streets, new governmental and cultural buildings were other actions occurred in regard to this official frame, these changes formed the basis for further development of main the structure (Hamidi,1997:42-43).

The orthogonal grid pattern of streets directed the growth of the city to the north- south and east-west directions. New elements and functions were shaped in the north and south of the city. Indeed, this period can be considered as a start for the separation of main component of city structure or change of continual pattern of structure growth to the disconnected pattern. Tehran University and The Central Train station are some of the examples. Therefore streets role as linear elements strengthened in this era (Habibi, 2004).

Introvert growth of Tehran occurred through changing the function of gardens and palaces into public functions or through construction in open spaces. In contrast, the construction of new street network and formation of functional centers along them along with architectural elements built separately in other parts of the city resulted in a simultaneous extrovert growth (Figure 20).

Figure 20. Extrovert and introvert growth pattern of Tehran (Hamidi,1997).

In summary physical structure of the city changed in this period and the city has hybrid structure: A center which is shaped after the traditional structure of the city and an orthogonal street network branching out from this center in all direction with small dispersed centers around them.

Architectural elements

In the Tehran style squares had a different organization in terms of concept, function and structure in comparison with the traditional midans. Toopkhaneh square and Baharestan were formal and symbolic representations of this change. In these squares instead of school, mosque, bazaar and palace, new components were located such as banks, municipality and post office. Bazaar was confronted with strong rivals such as cinemas and hotels which changed the form of the city with their new functions. Streets had nor the traditional role of recreation neither the contemporary role of traffic, but they found a new role as livable urban spaces.

In this style confrontation of old and new, contemporary and traditional, vernacular and foreign exhibits their first spatial and formal effects on the city. As a result streets and squares, with their new components, became places of gathering for “modern” people and Bazaar became a place for general public who still lived based on traditional lifestyle (Habibi, 2004).

Evolution of the city in Pahlavy dynasty was under the influence of modernism international movement. Haussmann inspired spatial and physical organization of cities occurred in Tehran as

well. The straight and wide streets of the 19th century Europe formed the foundation of future developments of Tehran.

Figure 21. Expansion of the city –Hamidi (1997).

Summary

The changes the form of Damascus, Cairo and Tehran went through are summarized in the following table.

Table 1. Summary of the changes in form in Damascus, Cairo and Tehran

City	Emergence	Islamic Period	Colonial/ Modernism period	Contemporary Period
Damascus	<ul style="list-style-type: none"> • Water distribution systems/ Canals • Infrastructure • Greek and Roman orthogonal grid 	<ul style="list-style-type: none"> • Formation of single buildings • Decline of orthogonal grid • Decline of public arenas • Formation of organic grid through time • Private gardens 	<ul style="list-style-type: none"> • Straight and wide streets • Disregard of the canals and existing infrastructure • Geometric patterns in new developments • Material change (from wood to stone) • Disregard of context and traditions 	<ul style="list-style-type: none"> • Using development ideas such as garden city, socialist city and gated communities • Public and shared gardens • Decline of old parts
Cairo	<ul style="list-style-type: none"> • 	<ul style="list-style-type: none"> • Rectangular grid • Royal and military use • Construction of walls around the city • Conversion of rectangular grid to organic pattern through time 	<ul style="list-style-type: none"> • Modernization modeled on renovation of Paris • Wide avenues around circular plazas • Paris along the Nile 	<ul style="list-style-type: none"> • Decentralization policies • Decline and Abandonment of old parts • Conservation and preservation plans for specific sites disregarding the surroundings
Tehran	<ul style="list-style-type: none"> • Good location and weather • Small existing settlement 	<ul style="list-style-type: none"> • Establishment of new buildings and walls • Organic grid/ narrow streets • Linear pattern of structure with important buildings surrounding it • Outward orientation of development though construction of mosques, bazaars and communities outside of the city boundaries 	<ul style="list-style-type: none"> • Construction of new buildings and gardens • Regeneration of texture and streets • Orthogonal street network in new developments • Continuation of organic grid in older parts • Formation of squares • Construction of new buildings in bigger plots with large open spaces surrounding them • Attention to the design of facades • Use of urban buildings to demonstrate power and create identity • Demolition and renewal of old parts • Dominant official buildings 	

Conclusion

Indeed, there are many factors contributing to the form of urban fabric and its elements, such as geographical, social and economic factors, this article attempted to single out one contributing

factor and tried to illustrate to what extent the governing thoughts of a city can influence the form and process of change in the city. For this purpose the form of the city, consisted of the urban fabric and architectural elements, was assessed in different periods: Islamic, Colonial, Modernism and contemporary.

Cases in this article demonstrated despite the similarities between each period in the cities, there is a great difference between the changes the form goes through in Islamic, modernism or colonial periods. The main point in the Cairo and Damascus was that the governing Islamic thought has changed the face of the city gradually and with respect to vernacular factors. Whereas in Colonial period the modernist approach has changed the form totally and rapidly through vast interventions.

Studies also indicate that in the Islamic period the changes made to the form are mostly limited to single buildings contributing to emphasizing the presence of Islam in the city or as a manifest to the power of the caliph; however the general form of the city has mainly stayed untouched in compliance with the local social and environmental requirements. In contrast, the colonial period is coupled with vast changes and modification to both the general form and its components due to the technological advances and the mass production trends. The changes in the contemporary period are however built upon the challenges that the modernist approach brought about and therefore take a more moderate route.

It is also noticeable that the scale of changes in each case in all three periods is different due to their unique situation. Definitely Tehran is somehow different because it has never officially been a colony. However it does not mean that the governing thought was not affected with international dominant trends. This led to new hybrid styles of traditional and new ones.

Finally, it should be considered that this research barely scratched the surface and there should be more extensive research on how the governing thoughts can and will influence the form of cities.

The evolution of neighborhood models as a manifestation of political regime shift: a case study of Cairo - Egypt

Islam Ghonimi, Ibrahim Ghonimi

Faculty of Engineering - Benha University

E-mail: islam.ghonimi@feng.bu.edu.eg, islamghonimi@yahoo.com.

Abstract. *Through history, Cairo witnessed different political regimes that caused consequential different neighborhoods models with varying socio-spatial characteristics. The research is to tackle the effect of Political regime on cities first in terms of their impacts on development manifesto, the role of development actors, and planning theory, then their impacts on the Evolving and declining neighborhood models. The paper will track Cairo development through history by Linking between the adopted political regime with development policy and their analogous impacts on Evolving and Declining patterns of urban development. This will pave the way to predict the future of neighborhood model form as manifestation of current and future political regime paradigm shift, especially after 25 Jan. revolution. In Order to achieve this goal, the paper based on a case study of 5 different neighborhood models at different chronological ages, an empirical analysis based on three steps: First, to document aspects of political regime and their impacts on development actors and planning method. Secondly, to measure the common socio-spatial patterns of evolving neighborhood model in three level analysis micro community, adjacent community, and macro community. Thirdly, to examine the correlation between the socio-spatial patterns of neighborhood models and the Political regime aspects.*

Key Words: Political regime, Islamic, Imperial, Socialism, Capitalism, Post-Capitalism, neighborhood

Theorizing the impacts of political regime on neighborhood models

This part of the research intends to theorize the impact of political regime on neighborhood models. Through three interlocking parts, the political regime, the impact of political regime on design and planning method, and finally tracing neighborhood models as a manifestation of planning method on political regime. This analysis method is used later on to test different political regimes and their impacts on evolving and declining neighborhood models.

Political regime

The political regime is a set of political structures that make up a state and determine who has access to political power. And it ranges from single to public involvement in decision making Fishman, R. (1990). Political regime can be classified under different headings based on democratic versus authoritarian, Van den Bosch defined three types of political regimes based on type of government; the single, aristocratic, and democratic (Van den Bosch, J. - 2013):

i) Autocracy (Dictator-Single) Regime

In this regime, government is carried by an absolute ruler, in which a supreme power is concentrated in the hands of one person, whose decisions are subject to neither external legal restraints nor regularized mechanisms of popular control when other states call the head of state dictator, that state is called dictatorship (Gordon 1987).

ii) Anocracy (Aristocratic-Elite) Regime

In this regime, government is carried by a group or class considered superior to others. is a regime-type where power is not vested in public institutions but spread amongst elite groups who are constantly competing with each other for power .

iii) Democracy (Public) Regime

In this regime, government is carried by representative are elected by citizens to make political decision for the people, a doctrine of or belief in social equality or the right of all people to participate equally in politics.

The relation between politics and urban form always exist, but it was much clear in large political paradigm shifts. There are different causes of politics paradigm shift. It could be based on religion shift, just like the shift from Aton religion into Ekhnaton religion, and the shift from the sunny into shea. It could be based on an economic shift, just like the political shift from communism into capitalism (Fatma, 2013). On the other hand the political paradigm shift should have consequences on the society structure and methods of production, and of course on architecture and urbanism.

The impact of political regime on urban planning method

The type of political regime could impacts urban planning methods; it also impacts the role that different development actors play in the political decision making and design methodology. It also impacts the degree and power of intervention of each group. For example in the dictator governance, the emperor is the only one who can take the decision. On the other hand, in the aristocratic governance, the elite benefit group even they were politically, socially, politically elites or they were ethnic groups. On the other hand, in the democratic governance, the public have great impacts on decision making.

Role of development actors

Authority, developer, planner, community and interest groups are actors that are sharing with varying values in decision making in urban development. According to the type of political regime, the type and degree of the role that each of these actors play in urban development are defined, and consequently impact the process and methodology of producing urbanism. This role ranges between complete controls, partial involvement, and complete neglecting in decision making. Beside, defining the primary and secondary role in urban development represented in regulator, developer, and builder:

- (i) State Role, represent the state political manifesto. According to political regime, its primary and secondary role ranges between being regulator, developer, and builder.
- (ii) Private sector Role, that works to achieve money capital benefits. According to political regime, its primary and secondary role ranges between being developer or reduced to be builder.
- (iii) Planner Role represents the technical role; According to the political regime, the planner works for the state to achieve public benefits, or work for the developer to achieve private
- (iv) Community member, who benefit of architecture and urbanism, and the only affected with the political decisions.

According to the political regime, the Regulation role ranges between Common regulations that carried by the people themselves, or intended written regulations that carried by the state with strong governmental legislation framework, or unwritten regulations that carried by the developer with New-private legislation framework instead of the weakness of the authorities legislation framework.

Planning methodology

According to the role of development actors involved in planning and decision making, three types of planning method are used:

- i) Central/comprehensive/holistic Model: A central planning method is used for the complete control on decision making, take place in dectator governments. Planning is considered as a scientific-technical process without any involvement of the public (Kinyashi 2000). Where the planner work for the dictator to achieve their trends, and develop a master plan.

ii) Incremental/advocacy/ participatory Model: An involvement of the public in planning methods, the planner work for the public in planning method, the planner obeys strategic plan, where all interest groups should permit the plan.

iii) Market oriented planning model: It is used with incremental strategy to meet market needs, most commonly used in capitalist communities, where the market controls the incremental modification of the plan. Depending on the regulation role of government, It can operate in two ways, the first with weak legislation role of the government, the monopoly take place and the customer (private sector) controls with monopoly all development aspects to achieve his benefits, the second, with strong legislation framework, the incremental modification take place for the benefits of the consumer.

Tracing the impacts of political shift on urban form

Neighborhood Models have witnessed a large shift as a result of the Political shift. To test this hypothesis, a previously developed spatial analysis tools are used to trace the ways in which political regime impacts the social and spatial fabric of cities (Ghonimi et.al, 2011).

In order to achieve this aim, the research depends on three levels analysis. First, the way political regime impacts spatial and social fabric of micro community is traced. Second, the ways in which these socio-spatial features change the continuity and relationship with adjacent community and consequently impact the social and spatial fabric of adjacent community is deduced. Third, the way in which these communities collectively impact the social and spatial fabric of macro community is deduced (Ghonimi et al, 2011).

Figure 1. Three level analyses.

Neighbourhood socio-spatial characteristics

Street network pattern, land use pattern, and housing pattern are socio-spatial characteristics of neighborhood model, that are used to manifest political regime (Ghonimi et.al, 2011).

Street network pattern ranges between grid, loop, and tree patterns their spatial structure can be classified under heading of type of street, Linear feet of streets, number of blocks, number of intersections, number of access point, number of cul-de-sacs, percentage of streets area.

Figure 2. Alternative street network pattern (Carmona, 2003: 73).

Land use pattern can be classified under heading of landuse type, variation and density. The (dividing vs. connecting) line between different landuses represent the mixed vs. separation of landuse as a manifestation of political regime (Ghonimi et al, 2011).

Figure 3. Alternative land use patterns (Ghonimi, 2011).

Housing pattern can be classified under heading of landuse type, variation and density, they can be measured using the (dividing vs. connecting) line between housing types. It represents the exclusion vs. segregation of housing types as a manifestation of political regime (Ghonimi et.al, 2010).

For the social governments this line is called connecting line (not dividing) it increases social benfits through creating a relation between different social groups, according to Butman it creates much more social capital. For the post capitalist governments this line is called dividing line (not connecting) it reduces capital benfits through creating a relation between different social groups, it reduces the mony capital of the developers (Ghonimi et.al, 2010).

Figure 4. Alternative housing patterns (Ghonimi, 2011).

Adjacent Community socio-spatial characteristics

Micro Community socio-spatial pattern constitute the way neighborhood models create it's relation with external social-spatial fabric, and determine how to encourage or discourage connectivity, accessibility and interaction with its adjacent neighbors and with its boarder city. The relation between the new development and its existing context determines its way of social, economic, political, and functional interaction.

Spatial Fabric: The (dividing vs. connecting) line neighbourhood and adjacent community, represent the type and degree of inclusion vs exclusion of the neighbourhood model. It can be measured through No. of egress, No. of continued streets, Parameter, type of parameter, Length of parameter.

Social fabric: The (dividing vs. connecting) line between neighbourhood housing type and adjacent community housing type, represent the type and degree of social inclusion vs social exclusion of the neighbourhood model. It can be measured through length of line between Micro to macro housing type, variation, and difference.

City socio-spatial characteristics

The type of the relation between micro community with adjacent community constitute the pattern of the city, which Visualizes the ways in which these socio-spatial features are collectively reshaped the socio-spatial fabric of public and private realms of the city.

The case study of Cairo

The following part will examine the impact of political regime in term of (development actors, development methodology) on the evolution of neighborhood models. The field study will go through four stages to achieve these goals. First: Case study selection: 5 case study areas are selected. Second: Data Gathering with defining methods, and tools, of collecting. Third: Data Classification including the documentation and measurements of the variables. Finally: Data analysis: undertaken to test the hypotheses of the research to reach the results.

Cairo is exposed to different changes of political regime starting from the origin islamic, Impiral, Socialism, Capitalism, and post Capitalism. Thus undergoing a dramatic shift on neighbourhood models and city form. The case study of Cairo will be investigated through describing the effect of changing political regime on urban legislation, planning proceeds and role of development actors. Then describing the resulted changes on the urban form. The data related to socio-spatial characteristics were measured using different measurement tools and their scores are presented in table (1,2).

Cairo's political changes and the urban form

To understand the changes that took place in Cairo, first a portrait will be drawn of the original political and urban form of the traditional city followed by its steps towards current states.

The Islamic Cairo (the impacts of Basic principles of Islam on urban form)

Cairo under Islamic governance, passed through different political regimes, with different government types, it ranges between the public and the aristocratic governance depending on different factors:

- i) The religion versus mundane tendency;

ii) The type and degree of dependency as an Emara depend on the Caliphate, or independency as in Tolon and Fatimid;

iii) The fundamentalism versus multi-nationality and the degree of foreign intervention.

Starting with Rightly Guided Caliphs, Muslim authority were adheres with the religious tendency. Fustat was established by Arab military commander 'Amr ibn al-'As to be the first Islamic capital of Egypt. The Doctrinal base of No damage or harm in Arabic "La Darar nor drar", was a guiding role in shaping urban form. This was reflected on the city form (Fostat):

i) street network pattern: A Central and radial street network pattern is used to link all city with the mosque as the central element of the city.

ii) land use pattern: Land use are characterized by variety of deferent types of uses, Starting from the mosque as the center of the city, and to be the authority place at the same time, it was partially surrounding the central mosque by different layers of interconnected markets (suqs), Ending with residential and commercial uses, all land uses were mixed with each other, except the crafts that cause harm to residents, is excluded out the city, respecting the Doctrinal of "La Darar wala drar".

iii) housing type: Fustat was mainly characterized by its intermixture where the poor and the rich inhabit the same alley (hara). This caused homogeneity in social fabric; there was no social division between the rich and the poor.

Moving Egypt to Abbasid Caliphate, Al-Askr was established as the new Abbasid capital of Egypt. Abbasid Caliphs used foreign Persian elements, they shift the governance from public democratic into aristocratic governance that bring with them the luxury life style and bring the stratigraphic trend, also this caused a reduction of religious tendency and instead increased mundane tendency. This was reflected on the city form (Asker) with following patterns:

i) street network pattern: A Central and radial street network pattern still used to link all city with the mosque as the central element of the city, with filling the spaces between the fingers.

ii) land use pattern: The mosque was removed from the city center and replaced with governmental palace and princes palaces attached to the center.

iii) housing pattern: Fundamentalism to multiple nationalities, a social division between the aristocratic foreigner governors and the public poor exist. The city become composed of consecutive rings the center is the authority palace, the mosque and commercial areas, the next ring locate princes houses and the next ring high level governmental employees, and the outer ring the public poor residents.

Moving Egypt to Tulunid Emara. The Turkish Ahmed Ibn Tolon, accounted for the authority for himself. He shifts the governance from aristocratic into single governance. Ahmad ibn Tulun established Al-Qatta'i as the new Tulunid capital of Egypt. It was founded with a change in the governance from emara depend to the khelafa into an independent entity. This was reflected on the city form (Al-Qatta'i) with following patterns:

i) street network pattern: A Central and radial street network pattern still used to link all city with the mosque as the central element of the city, with filling the spaces between the fingers.

ii) land use pattern: The role of the mosque is reduced and replaced with the governing palace, mosque, commercial area that are placed at the center of the city.

iii) housing type: Apartheid regime is growing where a layer of who is closer to the governor, were dwelling near the central layer and excluding the poor in the outer layer. So a social division exists between the rich and the poor.

Moving Egypt to Fatimid Caliphate. It was a Shia caliphate, They originated Fatimid Cairo, al-Qāhira (Cairo), to the north of Fustat, When Al-Mu'izz ordered Jawhar Al Sikilli (the Sicilian) in 973 to build the Fatimid new capital in Egypt. They worked to encourage Egyptians to turn from sunni to shai, in order to achieve this goal they built the city with following patterns:

i) street network pattern: A linear street network pattern started to be used to accommodate a multifunctional core connecting the city two mosques.

ii) land use patterns: a multifunctional mixed land use core connecting structure enveloping between the two mosques Al-Azhar and Al-Hakim to publish the shai doctrine, they built two palaces at the middle of the core, for the caliph and for his heir, opposite and facing each other, to practice different celebrations in order to extract Egyptians to Shia. The two mosques, in addition of being the place of prayer, their courtyards serve as the primary public open space of the city.

iii) housing type: the turn from Fundamentalism to multiple nationalities caused a social division between the aristocratic foreigner governors and the public poor. The city become composed of consecutive rings the center is the authority palace, the mosque and commercial areas, the next ring locate prince's houses and the next ring high level governmental employees, and the outer ring the public poor residents.

Moving Egypt to Aube Caliphate. It was combined with two political shifts, the first is to eliminate the impacts of Shea doctrine and to encourage the shift from Shea to Sunni Doctrine, and the other is to face the external potentialities of the crusade and Tatar invasion. In order to achieve this aim they made some political strategies that are reflected on urban form:

i) street network pattern: A multifunctional core still exists, with increasing development areas and controls the development with fences and walls.

ii) land use pattern: They incorporated new building types inside urban fabric named schools, to fight the Shea doctrine and publish the Sunni four Doctrines. They moved the government palace from the center of the city in to a place far to the east over a higher hill and built fences and gates around Cairo, they build a defensible urbanism.

iii) housing pattern: Due to moving the governmental palace from city center to the castle, the house of the governor and his lords and mukluks are moved to the citadel, the matter that caused a separation between governor's elites and the public. Accordingly, the city become much more homogeneous and the streets still contain different housing types in the same alley.

Moving Egypt to Mamluk political regime aimed to two shifts; a repeated shift from Fundamentalism to multiple nationalities, and the insertion of feudal system, where the lords give ownership of lands to the senior statesmen. In order to achieve this aim they made some political strategies that are reflected on urban form:

i) street network pattern: Keeping the linear street network with increasing extension areas.

ii) land use pattern: new patterns of multiuse buildings that contain schools, hospitals and shrine.

iii) housing pattern: Multi-nationality and Feudalism become tools that caused an extreme social gap between the rich and the poor and caused a social division and segregation. It was reflected on the housing pattern variation, and separation of housing types.

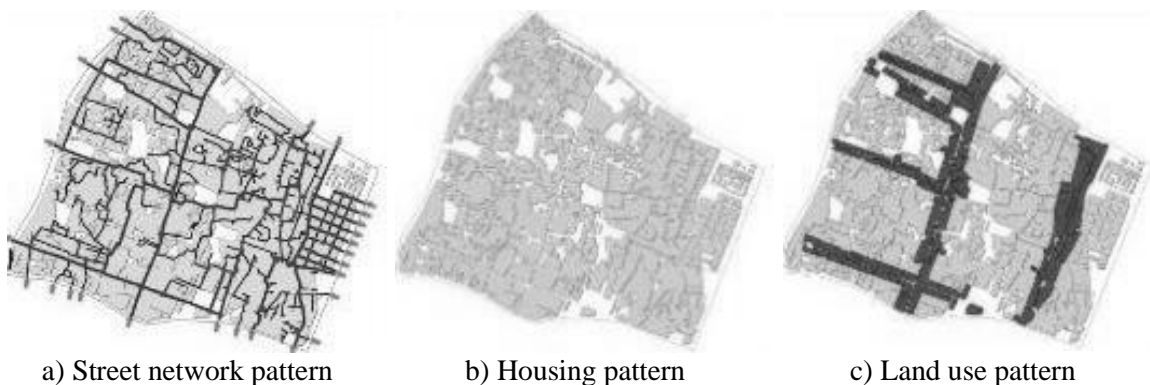

Figure 6. Spatial analysis of Islamic Cairo neighbourhood model.

Neighborhood manifestation of Islamic political regime

Micro community socio-spatial patterns:

i) street network pattern: At that era movement system was still depending on pedestrian, so an organic and spontaneous street network was used, their form was a reflection of the inhabitant's beliefs and neighbourhood right. Street is called (SHAREA) where the place that manage the social relation between community members, the Doctrinal base of No damage or harm in Arabic "La Darar Wala drar", was a guiding role in shaping their form. And this doctrine created the unique Islamic regime with homogeneous urban form.

ii) land use pattern: the Land use pattern was focused on mixed and multifunctional land use core structure enveloping, at least partially surrounding the central mosque by different layers of interconnected markets. Specialization of neighborhoods of the city which housed workers, craftsmen, religious and governmental officials sprung up around the centralized structures. Commonly the land use pattern were ranges between residential and other service uses, mosque, governmental palace; but mostly they were mixed with long connecting line between different land use, unless a hard factories or harm crafts that are excluded out the residential area. Beside it is mostly based on high density development.

iii) housing pattern: Housing pattern was focused on variation, diversity and intermix of housing types, Except some foreign Persian elements that are brought by Abbasid Caliphs, Created some elites' residences were located around lakes e.g. Birkat Al Fil or on the borders of the Birkat Azbakya, make social segregation between aristocratic foreigner governors and the public Egyptian residents. Cairo residents most commonly are distributed in a wide range of housing types, but it was mainly characterized by its intermixture (social mix) where the poor and the rich inhabit the same alley (hara) (Abo El Ela, M., 2003). A long connecting line between different housing groups was enough to create social inclusion based on common appropriation and transformation of public space by the various social groups.

Macro socio-spatial fabric:

i) relation between neighborhood and the city: In this period, micro urban forms of cities were seen as integrated urban settlements with neighborhoods as divisions of the city, integrated and linked organically and structurally to its existing city structure, its center, and the main civic functions. It showed a connection to the city, the large urban environment, and the community life surrounding it. It does not miss the basic function and nature of being an entity of a larger urban area; it cannot lose its role in the life of the city. In addition, it was not a standalone cell rather it was an interconnected reality. Neighborhoods were permeable communities that regularly interact both communally and on an individual basis with the whole urban community and larger sociopolitical structures.

ii) social fabric: The long connecting line between different housing groups in micro scale creates homogeneity on macro social fabric, and the social fabric of old Cairo gives a feeling of socio-spatial continuity (Bianca, 2000).

iii) community life: The civic life of the city was its focal point and was usually organized along a central point the mosque and sometimes along a linear scheme commercial axes. This relationship between the neighborhood and the town by means of its principle streets. Neighborhood activities stretched out from the crossroad intersection along the main street in either direction (Lott, 2004), and were connected to the center of the city that resemble the link to city life (Duggan, 2007: p.24).

iv) loyalties: It tends to create public loyalties between the neighborhood and town. It seems to create a large integrated society within a large community context.

The Imperial Cairo

Imperial Cairo was ruled under governance of French expedition (1798- 1801), Muhammad Ali and his successors (1801-1882), and British Colonialism (1882-1956), passed through different

political regimes, with the same target of the process of Cairo's westernization, and not modernisation¹. Westernization as apolitical orientation creates the role of development actors and accordingly development method:

The westernization of Cairo was not truly under way until the reigns of Muhammad Ali's successors during the second half of the century, (Abu Lughod, (1971) and Bianca, (2000)). The westernization of Cairo was catalyzed in Khedive Isma'il reign. The British colonial occupied Egypt for about 70 years, they continued the line of westernization (Stewart, J. 1999).

Wide Westernization steps took place through, the construction of European-style urban form, in addition to a proliferation of private foreign communities; Ismael depended on foreign architects and planners to build Cairo according to European plans, and the British colonial brought foreigner private developers, who started to contribute in the urban development, different new settlements in different locations, just like Heliopolis, Maadi, Garden city, Zamalek, and Roda.

The role of Development Actors

The aristocratic governance of Cairo due to the process of westernization and private sector intervention in development, a new change in the role of development actors, where the state lost its role in development, in the other hand the foreign developer's role is increased to be the developer and the regulator. The urban planner works for the developer, and private domain.

Figure 7. Spatial Analysis of Imperial Cairo neighbourhood Model.

Neighborhood manifestation of Imperial political regime

Micro community Pattern

ii) street network pattern: the applied European style in the urban form and buildings of the new part of Cairo was characterized with transition to radial patterns of development which caused the wide spread of urban form. This impact the intensive connectivity, where the paths and nodes are combined to create the common visual image of the city (Abo El Ela, M., 2003).

ii) social pattern: a low quantity of dividing lines between different housing types exist, that reflects a continuous homogeneity of foreigners and elite Egyptians with exclusion of others public poor Egyptians.

iii) land use pattern: a high quantity of connecting lines between residential and other commercial uses, that reflects expanded transit commercial axis which combines different vertical mixed uses, residential with commercial in ground floor.

Micro to Macro Relationship

i) spatial fabric: in this period the city was designed as connected neighborhoods which are connected in an organic way that resemble neo-traditional developments in their modified radial connected street networks, high density, moderate accessibility to bus stops, and ample

multi-family residential uses. Also, encourage of commercial uses and the neighborhoods engagement from the rest of the region. , and the public life was an important aspects with its radial streets and nodes. , and the public life was an important aspects with its radial streets and nodes.

ii) social fabric: a high quantity of connecting lines indicates social exclusion, were designed according to the European plans, especially on the model of British Garden city, which started to show a process of socio-spatial segregation, foreigners and upper-class Egyptian share the same life style. Their planning was mainly based on having separate residential districts, with their services clustered on main corridors. The colonialism introduced an alien cultural system and did not favor a smooth integration.

Macro community socio-spatial model

i) spatial fabric: in this period, micro urban forms of cities based on TOD, were seen as integrated urban settlements with neighborhoods as integrated and linked organically and structurally to each other, its center, and the main civic functions. It showed a connection to the city, the large urban environment, and the community life surrounding it. It was an entity of a larger urban area; it revealed its role in the life of the city. In addition, it was an interconnected reality. Neighborhoods were permeable communities that regularly interact both communally and on an individual basis with the whole urban community and larger sociopolitical structures.

ii) social fabric: the wide range in social structure of Egypt starting from the king family, authorities,, and foreigners that constitute the high economic level social group, to the mid economic level Egyptian residents, to the low economic level of the public residents of workers and farmers. This variation composes a wide range of housing types, but they were commonly excluded from each other, creating a wide gap between the rich and the poor exist.

iii) community life: the civic life of the city was its focal point and was usually organized along a central point the mosque and sometimes along a linear scheme commercial axes. This relationship between the neighborhood and the town by means of its principle streets. Neighborhood activities stretched out from the crossroad intersection along the main street in either direction (Lott, 2004), and were connected to the center of the city that resemble the link to city life (Duggan, 2007: p.24).

iv) loyalties: it tends to create public loyalties between the neighborhood and town. It seems to create a large integrated society within a large community context.

Cairo under socialism (Revolution and Republic) (1952-70)

Moving Egypt to Socialism, Egypt has been ruled by Abdel Nasr. In this time, Egypt, through revolutionary action, managed to establish its independence. This period had witnessed an accelerating move towards Egytianisation, Revivalism, and Socialism in various aspects, that put the poor and the rich in the same interst, the state take the role of development e.g. Nasr City.. Under Socialism, A public governance is used, where a doctrine of social equality to participate in politics. The Political shift from Imperial to Socialism has narrowed the gap between the rich and the poor and settled the doctrine of social justice, equity, equality.

The role of Development Actors

The shift to socialism is reflected on the role that public sector, developers, and planner play in urban development. The authority put the poor and the rich in the same interest, the state take the role of development, in search for social justice and equity. The authorities take public responsibilities. The private real estate developer, Authority role means the existence of little or no private sector intervention upon economic issues, their role was reduced to be builders. The urban planner works for the state, and public domain.

Planning Method

A central planning method take place, Central/comprehensive/holistic Model: it concerned the complete control on decision making, there is no right solution as time, money, information and mental capabilities of the planners are not sufficient (Kinyashi 2006; Mitchell 2002). Planning is considered as a scientific-technical process without any involvement of the public (Kinyashi 2000).

Neighborhood manifestation of Socialism political regime

A new trend toward process of Egyptianization, Revivalism, and Socialism; that put the poor and the rich in the same interest, the state take the role of development e.g. Nasr City.

Figure 8. Spatial Analysis of Socialist Cairo neighbourhood Model

Under a political orientation, western neighborhood unit is adopted, and used in Egypt development. Socialism political regime based on a Neighborhood patterns, that are drawn from western, but until now and according to the socialism Philosophy it encourage the social justice, social equity, equal distribution of resources and benefits, and inclusion, on the other hand it encourages inclusion of others, all have wright to benefit urban life, services, urban spaces, and all facilities. In order to achieve this aim it takes different patterns as follow:

Micro community pattern

i) street network pattern: Socialism search for social equity of accessibility so it centered plan on Grid network plan connected to each other and enable continuous connected outward oriented growth to enable the connection between different parts of the city and facilitate accessible bus services and alternative transportation options.

ii) land use pattern: the authority responsibility to provide services make it use different types of land use as services area for education, medical, administrative, cultural, entertainment and sport, commercial services, with respecting to make all these services and facilities accessible for all community residents.

iii) housing pattern: in dealing with a number of demographic problems due to the rising population and the migration of residents of the canal cities, And according to socialism it tends to narrow the gap between social groups, so it aims to standardize housing types with little variation between housing groups. A standardized cooperative housing residential building were constructed (Nasr City, muhandseen). So it is characterized with little variation, High social mix, High density,

iv) community life: centering the plan on public domain, make it compatible with the character of urban life, mobility, diversity, the desire for choices, and the need for larger areas for social interaction, which are aims of socialism.

v) loyalties: it tends to create public loyalties between the neighborhood and town. It seems to create a large integrated society within a large community context.

Macro community pattern

i) spatial fabric: The micro community pattern is spatially connected to each other, they are part of a continuous fine-grained pattern. They encourage community, connectedness and integration, focusing on public realm. Whereas, in macro level enable accessibility, permeability and continuity in the overall urban fabric.

ii) social fabric: The narrow gap between community residents eliminate the social exclusion, and achieved social homogeneity in social fabric.

Cairo under Capitalism (The adoption of the open door policy) (1971-1980)

Moving Egypt to capitalism, Egypt has been ruled by Sadat. In this time, Egypt like many other countries in the world has been drawn in to a dramatic economic and social change, a change in the adopted Egyptian socio-political regime from the societal ideology to the capitalism ideology, it is followed by the economic restructuring and the transition towards open door policy (Bayoumi, 2009). The first legislative step towards the open door policy appeared with the Law 65 of foreign investment, which paved the way for a vast market for investment and commercial banking, (Yousry, Abu-Zekry and Yousry, (1998)). Its chief purpose was to attract Arab and foreign investment capital under highly favorable conditions.

Open door policy make two shifts in development policy and social structure of the community. The shift in system of organization and governance and consequently adopted policies that have reshaped development tools and methodologies and directed the trend of development toward the market privatization, and development through private sector developers. The socio-economic gap has widened between the fixed-income earners and a new capitalist class who gained from the new economic dependency.

Large personal investments took place to serve the upper and high-middle class of Cairenes through the establishment of non-governmental private uses. On the other hand, the government was more directed to solve the pressing problem of the boorst and concentration of population through the creation of new urban centres with new economic activities and better facilities in an attempt to attract people to a better life. Under Capitalism strength of the state regulating role still exists, that is required in a market economy. The strong governmental legislation framework, enable the state to regulate urban form in a suitable manner.

The role of Development Actors

The change from social economy into free economy leads to a change in the role of development actors: The state role is reduced to be just the regulator of development. A strong governmental legislation framework, the state can control and regulate urban development in a suitable manner, with an explicit written known regulation. The developer role has transformed from being the builder to be the developer and impact regulation. The planner role also has been transformed; he does not work for the state hopefully to take part in the state development for the public, rather the planner works for developers that make earn more money at the top of their priorities.

Planning Method

An Incremental planning method take place, market oriented model: it concerned the market controls the incremental modification of the plan. It operated with strong legislation framework, the incremental modification take place for the benefits of the consumer.

Neighborhood manifestation of Capitalist political regime

Under a political orientation, western neighborhood unit is still adopted and used in new town wave of Egypt development. Capitalism political regime based on Neighborhood patterns that are drawn from western, it started using strong legislative framework to encourage the social justice, social equity, equal distribution of resources and benefits, and inclusion, on the other hand it encourages exclusion of other. In order to achieve this aim it takes different patterns as follow:

Figure 9. Spatial Analysis of Capitalist Cairo neighbourhood Model

Micro community Pattern:

i) street network pattern: capitalism under strong legislative framework can still achieve social equity of accessibility so it centered plan on the use of loop systems, to achieve safety and reduce car penetration without losing benefits of Grid network plan that is connected to each other and enable continuous connected outward oriented growth to enable the connection between different parts of the city and facilitate accessible bus services and alternative transportation options.

ii) land use pattern: The authority responsibility to provide services make it use different types of land use as services area for educational, medical, administrative, cultural, entertainment and sport, commercial services, with respecting to make all these services and facilities accessible for all community residents and at equal distance from community members.

iii) housing pattern: To face the wide gap between the rich and the poor and according to capitalism tends, so it aims to provide housing for different housing types with wide range. New community wave were constructed (as in first community and fifth community at East Cairo and second and third community at West Cairo) to inhabit wide range of social groups. But still the state intervention and strong governmental legislation framework used to achieve social justice and intermix between different social groups. It is characterized with little variation, High social mix, High density.

iv) community life: Starting to shift centering the plan from public domain to private domain, make it in compatible with the character of urban life, mobility, diversity, the desire for choices, and the need for larger areas for social interaction.

v) loyalties: it tends to create public loyalties between the neighborhood and town. It seems to create a large integrated society within a large community context.

Macro community Pattern:

i) spatial fabric: The micro community pattern is spatially semi connected to each other and to context hence, they are part of a continuous fine-grained pattern. They discourage

connectedness and integration, focusing on private realm. It reduces accessibility, permeability and continuity in the overall urban fabric.

ii) social fabric: A high quantity of connecting lines indicates social inclusion, and mostly heterogeneous housing type. They are connected to their context, so they are socio-spatial inclusionary pattern, which strive for gathering different housing types, and different parts of the city.

Cairo under Post-Capitalism (1980-2011)

Moving Egypt to post-capitalism, Egypt has been ruled by Mubarak, his policy worked to achieve the liberalization of Egypt's economy. From 1991, Mubarak undertook an ambitious domestic economic reform program to reduce the size of the public sector and expand the role of the private sector. In order to achieve this goal the state regulating role is changed. A shift in the nature of contemporary "Economic-Political Ideology" reflects a shift from capitalism to post-capitalism, a shift from free market economy to monopoly of market, a shift from keynzian policy that assume that the developers need control and strict strong legislations in to liberal policy that freed private sector of any control and follow the deregulation policy. In other words, it reflects the change from Fordism that depends on written explicit known regulation to Post-Fordism that depends on oral implicit unknown regulations (Csfalvay, 2009). The government may not yet play the strong regulatory role as before, so the weakness of the authorities legislation framework cause the emergence of New-private legislation framework with new standards, (Abdel Khalek, 2009).

An Extreme economic-Political Shift cause a social shift, that widen the gap between the rich and the poor, the laissez - faire deregulation public legislations, and the new private legislations all are factors influenced the process of development. These factors are reflected on various development actors which can be explained as following: the first actor is wide gap between the rich and the poor. As a result the rich seek for exclusivity, protection and lifestyle inside Gated Communities. Besides, the public sector bureaucratic make the state fail to provide better environment that is suitable for the high class residents, the matter that make them search for enhanced built environment, this is exactly what the private developer succeeded in achieving inside a gated privatized area. The private real-estate developers have more efficiency than the public sector, therefore private developers gained large acceptance in real estate development especially from high class residents. One should argue that private sector is not completely new, but its role to impact and shape urban fabric and hence shape their role in development, was always related to what the authorities permit and regulates to them through development control. The third actor is the state; the shift to open door policy is reflected in the role that private sector developers play in urban development. The authorities aimed to evade public responsibilities, even its role in regulation, reduced with adopted laissez faire deregulation policy.

The role of Development Actors

Bayoumi (2009) argued that the doctrine of the laissez faire ideology is based on three concepts. First, developers see regulations as an infringement of their freedom, even when regulations are about issues such as preserving or at least slowing down the rate of environmental destruction (Henry 2008). Second, it is wise to protect the property and privilege of the wealthy and powerful assets for the benefits of the whole national economy (Waller, 2006). Third, it relies on enabling the well-specified property rights and the activities of the free market enterprise to reflect the beneficiaries' real interests (Aune, 2001).

The state adopted laissez - faire deregulation policy, that means the existence of little or no state intervention and controls upon economic issues (Holmes 1976 & Waller 2007), on the form of free markets, minimal taxes, minimal regulations, and assuring the private ownership of property. The role that private sector developers play in development has changed where the

developers put forward their new-private legislation framework and design principles (Abd el khalek, 2009), and begin to contribute to the production of urban form and space.

The role of state under the adopted *laissez-faire* deregulation policy started to diminish and restrict to just being an observer of development. It became weak enough to leave the arena of development in the hands of private sector developers permitting them to take decisions according to their commercial interests. The state obeyed developers requests, letting them act and make changes in the spatial development of urban form.

The case of GCR shows how decisions taken by municipal public sector, in most cases, permit developers to take decisions according to their commercial interests. Municipal urban legislation, in most cases, has been changing all the time in order to meet private interests, without consideration about effects over these local boundaries, it is easier to accept developer's decisions. The state in most cases fulfills developers' requests, letting them act and make changes in the spatial development of urban form. The government produced private oriented legislation because of a political decision and the developers' stresses. The state role is blind in not taking in mind the macro public responsibility.

In the meantime the privatization theory revolves around the argument contend with its ability to save money and seeks for fast sales, benefiting a small group of people who have the affordability to pay, with detriment of the majority of the population and consequently affecting public actions.

Indeed, high class residents seek for exclusivity, homogeneity and protection; private actors contribute to the production of space (social selection of residents, control management of total gated area); local public authorities have key strategies (*Laissez-faire* policy, development without bearing public responsibility, deregulation policy); and publicly-owned and managed areas tend to disappear, yielding to a private-owned and managed Gated Communities. The consequences and systemic impacts of these strategies, that built or restrict the public space, produce social selection of residents, impose externalities over the neighbors (implications on property values, on fiscal equalization, on segregation...). These strategies contribute to define the ability of public authorities to regulate the allocation of public space and to control urban planning processes.

Planning Method

An Incremental planning method take place, market oriented model: it concerned the market controls the incremental modification of the plan. It operated with weak legislation role of the government, the monopoly take place and the customer (private sector) controls with monopoly all development aspects to achieve his benefits.

Neighborhood Manifestation of post-Capitalist political regime

Urban form manifests the political shift it manifest the emergence of new patterns of private urban governance (Gated Communities). Gated Communities reflect the state adopted *laissez-faire* economic policy that reduces any state intervention against private sector control on urban development. The Egyptian context of post-modernism, revealed a continuation in the process of globalized, American westernization, new Gated Communities model become the dominant pattern for development in Egypt which relatively borrowed from the westernized, American model (Denis, 2003).

The expansion of Gated Communities in GCR began since the mid-1990s, become a mass trend in new town urban developments on the outskirts of the Greater Cairo Region when the government started to sell land in The new satellite cities around Greater Cairo, for developers to construct Gated Communities. They contribute to reshape the suburban landscape of GCR's new towns (Meyer 2000).

Figure 10. Spatial Analysis of Post-Capitalist Cairo neighbourhood Model.

Post-Capitalism manifested a Postmodern neighborhood models, an important change in the concept of neighborhood to be a more independent and self-contained unit that are characterized by:

Micro community socio-spatial characteristics(Ghonimi et al, 2011):

- i) street network pattern: Centering to be cellular model with inward oriented, intently and totally separated from the city, make it depends mainly on its own resources, and exclude others who are not engaged.
- ii) land use pattern: Centering the plan on a single facility and use, mostly residential, no mixed or varied or compact use.
- iii) housing pattern: Capitalism enhances micro social exclusion and macro social segregation. Centering the plan on single housing type, seems to be designed only for high class families, no mixed interconnected or varied diverse or compact social group.
- iv) community life: Centering the plan on private domain and neglecting the public domain, make it incompatible with the character of urban life, mobility, diversity, the desire for choices, and the need for larger areas for social interaction.
- v) loyalties: Gated Communities tends to create a division of loyalties between the neighborhood and town. It seems to create a small somewhat separated society within a large community context.

Micro to Macro Relationship

i) spatial fabric: Gated Communities are inward oriented Street network, with physical barriers that blend with adjacent network, and splintering them out from their context, hence they are physically excluding their adjacent area and segregating themselves from each other and from the overall image of the city, they creates inaccessible bockets, super blocks and islands inside urban fabric, that cut the continuity of urban fabric.

ii) social fabric: Gated Communities are closed area with homogenous social group that are closed of the entire spatial and social fabric of the city. This impact social fabric in two ways, firstly, it breaks the connection with adjacent Gated and Non-Gated areas even they were of different or the same housing type, secondly, it widens the gap between different social groups, which could weekend the socio-spatial fabric of the city. The spatial and socio-spatial exclusion of Gated Communities for its external urban fabric caused a dramatic impact on the social fabric of the city. The process of social exclusion and segregation exist, this could have its relevant impact on both micro restricted private community and macro excluded and segregated adjacent public community, which will be discussed and criticized in the next section.

Macro community socio-spatial characteristics

This shift cause many subdivisions to be built without reference or link to the city. Community life become much more limited to this subdivisions, and moved from totally focused on city public life to be totally focused on private domain. Gated Communities become the main development pattern in contemporary Egyptian city, which extends the concept of separation between micro and macro urban form in the city.

This process of privatization and orientation to private urban governance has begun to contribute to the production of urban form making its permanent impacts on the urban form and structure of greater Cairo region, that have been affected by the emergence and proliferation of gated residential developments.

A process of change on patterns of urban development from public spaces and open patterns to post public space and gated privatized pattern; this has cause the emergence of newly urbanized areas, an important change relating to these spatial outcomes is the construction of physical barriers that constrict connections within and between community members, via the deployment of gates and other design barriers around units of accommodation.

Splintering large public areas of micro urban form and isolating them out from macro urban form of the city, cause that publicly-owned and managed areas tend to disappear, yielding to a private urbanism in which planned unit developments (and Gated Communities and other forms of private urban governance) are key features. A housing consumption patterns can result in segregated areas a new phenomenon in micro scale known as enclaves, and in macro scale known as a Divided City.

This phenomenon has reshaped the face of urban life and has a great influence on the evolution of metropolitan area in term of its form and structure, which necessitates revisionist view for its impacts on urban development. Soja (1989) in "post-metropolis: critical studies of cities and regions", argued that these trends in urban development signify a major transformation in the physical characteristics of cities. Low (1996) in "Imaging and theorizing the city", conceptualized the impact of these patterns on the emergence of "Divided city", and "Fortressed city". Graham and Marvin (2002) in "splintering urbanism" argued that these trends impact the physical fabric of many cities across the world starting to fragment into giant cellular clusters (Ghonimi et al, 2011).

Conclusion

An analysis of Cairo neighborhood models, gives a great understanding of the impact of political regime shift on the evolution of neighborhood models, as follow:

The political regime impacts planning method and role of development actors as follow:

In single governance, a central comprehensive planning is used and the state primary role as the regulator, the developer and the builder, their regulatory role based on a written intended regulation with strong regulation framework. In aristocratic governance, an incremental, pecimal method is used, the state role is restricted to be the regulator as in capitalism with written strong regulations framework, and sometimes it loses its regulatory role as in post-capitalism based on unwritten regulations that carried by the developer with New-private legislation framework, and the developer role become much more stronger. In public governance, a spontaneous method is used, the people put common regulation framework.

The impacts of political regime are reflected on urban form as follow:

Street network pattern: Single and Aristocratic Governance tends to have division of loyalties, so it mostly use treed street network, in the other hand public governance tends to create equal access to urbanism so it mostly use grid street network pattern.

	Sakiya	Cen	Sakiya	Cen	Sakiya
Street Network pattern	Proposed public fine grain street network and public urban fabric. Fine grained: Free large number of entrances, No borders, continuous fabric, Overlapping and interweaving. The pedestrian transportation web. The predominantly pedestrian city was built over time -- with continuous incremental additions.		Implicitly Proposed public fine grain road network. Implicitly controlled Restricted Limited low number of Entrances, Arterial roads, Arterial roads as borders modern car city which cannot turn into a pedestrian city, that it is anti-fractal city.		Private super block road network and private urban fabric. Intentionally explicitly controlled restricted limited low number of Entrances, walls and Barriers as borders postmodern car city which cannot turn into a pedestrian city, that it is anti-fractal city.
Boundaries	Blurring boundaries: the neighborhoods' engagement with the rest of the region.		Outer Ring neighborhoods are distinct in Arterial streets. The neighborhoods' disengagement from the rest of the region.		Outer Ring neighborhoods are distinct in their physical barriers. The neighborhoods' disengagement from the rest of the region.
Housing pattern	Inclusionary of others, oriented toward the public domain and human dimension. Heterogeneity and ample multi-family residential uses.		Exclusionary of other, Socially restricted. Homogeneity in housing fabric		Exclusionary of other, Socially restricted. Homogeneity in housing fabric
Land use type	Public domain		Private -public domain		Private domain
	Macro Community				
					
	Al-Darb EL Ahmar	Talat Harb	Nasr City, Cairo	Al-Hal- ElMotamiz	Lyan, New Cairo
Street network	Connected fine grained public City Fine grained Transit oriented street network		Connected fine grained public urban form Fine grained Transit oriented street network	Divided Super block public urban form Super block Inward oriented street network	(B): Divided Super block public urban form Super block Treed inward oriented Development
Land use Pattern	A mathematical semi lattice model. Fractal, connected, regional city model. A series of interlinked compact nodes or neighborhoods		Anti-fractal, tree, divided model. A series of Super block divided cells		Spatially Segregated. Eliminate uses from public life
Housing Pattern	Socially inclusionary of connected between different housing types		Discontinuity through housing		Socially Segregation of diverse housing types
urban form	Public	Public	Private -public		Post public

Housing Pattern: Single governance tends to create homogeneity on micro scale and social exclusion and segregation macro scale, as in Mamluks, post-capitalism, and imperial governance, so it tends to create low quantity or no dividing lines between different social groups.

Democratic Public governance seek contact, social justice and democracy, so they work to involve different social groups in the same neighborhood; to be inclusionary of different social groups and macro social homogeneity, so it commonly tends to increase the connection line between different social groups.

Aristocratic governance tends to create division, segregation, and neglect public space aiming for post public space the matter that reduce residents opportunities for democratic participation. Aristocratic governance depends on replacing public spaces with post public spaces, in which diversity and freedom are lost, where segregation, social inequality, and disintegration of society are promoted, and ethics of deconstruction, exclusivity and individualism. A shift from space that reflects democratic participation and social resistance, into a space that is controlled without any permitted public response.

Power, ideology and space re-generation: Istanbul case

Pelin Pınar Özden

Istanbul University, Faculty of Political Science, Department of Public Administration, Urbanization and Environmental Problems Branch. E-mail: pinozden@istanbul.edu.tr

Abstract. *The role and desire of Power in shaping the urban space has always been existent throughout history. The urban space is a plane that is generated parallel to the ideology of Power. It is also a tool that transmits the existence and the ideology of Power to the society, and legitimizes the Governments. Power realizes this via reconstruction activities. Urban space is a kind of stage where these activities take place. Governments offer their ideology to the society in different ways so that the society is forced to live in an urban space that is shaped by Power's wishes and its rules. The situation in Turkey also is not different. During the urbanization process from the Ottoman Empire to the present, what shapes the urban space is largely the Power and its ideologies. Urban space has been regenerated with the symbols of Power, with the references to the past or with the rejecting spatial policies the past. In this study, the relationship between Power, ideology and space will be analyzed based on periods of Istanbul's urbanization process. Especially in the process after 2000's, the background of the increasing capability of Power and how it is constructed with through the European Court of Human Rights judgments, lawsuits, council decisions will be discussed.*

Key Words: power, ideology, capability, urban space, regeneration

Introduction

Throughout history, the power, the ideology and capability of State have always been the primary factor in space regeneration. State is the power that shapes, develops and regenerates the space, and the ideology behind this regeneration is its flag. The equipments that the State utilizes in the regeneration of space have become versatile through time. Spatial policies, and legal and institutional regulations are known as the essential tools used in the regeneration of space. The State has applied its ideologic goals firstly on Ankara with its spatial decisions. In Istanbul, this process has not been different. Space in Istanbul, with the turning points in each decade, has been produced over and over again with the ideology of the State.

The process of legal or institutional reconstruction that supports this process has gone through a difficult path. This study aims to analyse the influence of the State ideology on space through Istanbul experience, since the foundation of Republic of Turkey.

The role of power ideology at the space regeneration: theoretical perspective

One of the fields where the technological-economical and political ideologic process that started with capitalism and became clear with the Industrial Revolution was the city. (Ökmen, Parlak, 2008). The city and its spaces was the stage for the ideologic transfers.

Space is where the State strengthened and produced its physical and symbolic sovereignty. Foucault (1997) consolidated this claim by saying the space was also an area of the authority struggle. Dicle (2012) defines space as a tool that naturalizes and justifies the State and transfers the State's existence to the society. According to Castells (1997), the planned structure of city space was the tool of the political control, whereas the monumental buildings, monuments and squares transferred the ideologic structure.

Tuncer (2013) defines space as the combat area of those who regulate and discipline, those who live and coexist. In his opinion, the power that has the State tools determine the actions and

thoughts of the society. So, it makes its hegemony over social and spacial areas. Just like the State's plot of space with castles and churches, today there are different dynamics who shape the organization of the State in space. This organization, as Öztürk (2012) says, is the "political language of space". Lefebvre (1973) supports this idea as well. To him, "Space is not an ideology nor a substance cleaned from politics, it has always been political and strategic. The space is indeed shaped by the natural and historical dynamics, however this process itself was a political process."

At this point, the State gains importance. Uzbek and Dinçer (2009) summarize this process as the following table (table 1).

In this study, while the process in Istanbul experience will be separated into periods, the situation of the State will be discussed as well.

Table 1. Situation of the State According to Paradigms

	Pluralist- paradigm	Governing paradigm	Class-centered paradigm
Situation of the State	The State is not a power nor a verdict maker by itself, it stays equidistant to every group, it arbitrates. Policies are determined by the negotiations in groups.	The State is a power and a verdict center all by itself, In this context, it liberates itself from all the external social powers.	The State is under the determination of the sovereign class, Approaches why the State is capitalist: materialistic ve structuralist görüşler

Istanbul case

Throughout history, Istanbul, with its tangible and intangible values, has undertaken a mission of a world city. The ideology of the State has always been a great influence on the regeneration of this important city. Parallel to the change of the State, space has also kept this pace and transformed. This transformation can be analysed in many dimensions of different time periods of Istanbul. The process of spatial development of the city will be analysed starting from the frame of the study, Republic period, and then will be separated into periodical sections.

From the early Republic to 1980's

The regeneration of space parallel to the ideology started in 1920's with the Ankara experience. New Republic had to be the symbol of a modern and a western society. Without a doubt, it is not a coincidence that Ankara was selected to be the capital, with the foundation of the Republic. For the first time, the continuous "only big city" role of Istanbul, which had the experience of being a capital, has been shared with Ankara for one time only in the early years of the Republic. Besides the goal of security and easy access from all over the country, this small village in the middle of Anatolia both symbolized a victory against Bizantian and Ottoman, and also created an opportunity to render a city that symbolized the modern, new Republic. Space was the essential tool to construct a new society by regenerating it. Thus, it was necessary for the space to regenerate quickly.

This radical modernity project was put in progress by the hands of the State itself.

The way to socialization was possible by creating spaces to let them interact. This goal was aimed to reach with three urban dynamics: train stations, squares and public buildings.¹¹⁵ Relate to the conservative structure of the society, there was very limited squares in the Ottoman Empire.

Ankara was assigned to foreign masters, and the planning studies were started rapidly. Big boulevards and large and geometric squares for ceremonies were necessary not only for socialization and involvement of women in public spaces, but also for announcing the voice and the power of new Turkey. (Figure 1, Figure 2).

Figure 1. Ankara Güvenpark Kızılay Square 1942 (source:<http://v3.arkitera.com/h56692-gecmisin-modern-mimarligi-10-ankara---3.htm>).

Figure 2. Ankara Train Station.

The majestic public buildings that filled Ankara created a strong city image, and symbolized the city as a Capital and a officer city.

Planning was the most important tool in the urban regeneration. The first plan made in 1924 was the Lörchr Plan. Parallel to this plan, there was 198 houses made in 1925 as the first attempt to solve the housing problems of the officers.

In 1927, the municipality of Ankara brought three planners by sending a comitee to Europe, and assigned the planners to make a city plan, framed by the municipality. Harmen Jansen and two

¹¹⁵ In Istanbul, the entertainment areas will be tools as well; in fact, in the last periods of Ottoman Empire, some big steps were made to become a western society. The number of these western spaces that were founded in Ottoman augmented in the Republic times. Theatres, opera buildings, ball saloons of hotels started to take place in the city. Ankara followed this process more slowly because it was designed more like a city of officers.

names that he suggested commenced the planning studies. The plan also designed a “workers neighborhood” in the Northwestern city, in a partially muddy area, close to industry. (Figure 3).

Figure 3. Ankara Workers District (source: Yavuz F., Başkent Ankara ve Jansen, *O.D.T.Ü. Mimarlık Fakültesi Dergisi* , Cilt 7, Sayı 1, Bahar 1981, 25-33).

Although Ankara was transformed essentially into an officer city with Lörcher and Jansen plans, the worker and the officer spaces were the proof of the social class difference in this regeneration.

Modernist project also aimed to create a systematic development plan by praising the villager and the rusticity, and by focusing on education in the rustic areas. In this context, Ideal Republic Village project took place in the modern village space and the village life was plotted. Adorned with the necessities of modern life such as conference room, hotel, reading room etc., a modern village area was designed. Public houses and village institutes were important areas of the rural development.

Starting from 1930's, Istanbul has taken its role back from Ankara. Prost plans were made and applied between 1930's and 1950's. Space created a new Istanbul by transforming quickly. It is possible to classify this big regeneration in Istanbul under several titles:

Large scaled destructions, evacuation of history and disappearance of symbols

Destructions were the most important activities that regenerated the urban space. To modernize the city, particularly historical sections of the city were destroyed. The head of the Municipality and former governor Lütfi Kırdar, who established his housing policies with the statement: “The way to reconstruct Istanbul goes through mattock.”, demolished many historic buildings such as mosques, hamams and military barracks according to the plans of the famous urban planner Henri Prost. The great regeneration has started in the city in these years. In the same location as Gezi Park in today's Taksim Square, Topçu Kışlası (a military barrack) who is known for uprisings in history, was demolished according to the Prost's plan in order to build a park. In this way, a military symbol was also abolished. (Figure.4, Figure 5).

Prost plans created a high devastation on Istanbul and removed many historical values. Destructions abolished many artifacts that were proofs of the past. (Figure 6, Figure 7, Figure 8).

Figure 4. Topçu Barracks.

Figure 5 After the destruction.

Figure 7. Anterior of the Historical Valens Arch (source: İAM Archieve).

Figure 8. Destruction of Dolmabahçe Palace Barns (source: İAM Archieve).

In 1956-1957, Istanbul Governor Fahrettin Kerim Gökay played a huge role in the transformation of Istanbul in the destructions, particularly in Zeytinburnu and Kazlıçeşme in terms of industry-dependent urbanization process.

In 1967, the first shopping mall of the Republic of Turkey, Manifaturacılar Bazaar, was opened after the expropriation of hundreds of parcels. The area of the Bazaar, in front of historical Valens arch, possessed many examples of civil architecture. (Figure 9).

Figure 9. Construction of İstanbul Drapers Bazaar (source: İAM Archive).

In the early periods of the Republic, it can be said that the ideologies of the new and the old States have observable differences, in terms of the regeneration of urban space. The buildings that symbolized the history were started to be utilized for cultural or administrative purposes.

When Sultanahmet Mosque was turned into an art gallery, Hagiasofia was turned into a museum and the Street names who carried the names of the Ottoman Sultans were changed, this separation between two ideologies were clear.

Looking for a New and Unique Architecture

While the buildings and the functions that represent history regenerated, public and cultural buildings, public houses, large and geometric formed square shaped the new cities of new Turkey. The rational, pozitivist ideology of the Republic guided the regeneration of space.

A search for a nationalist formed architecture was apparent, which the masters strongly supported. Behçet and Bedrettin (1933) stated this approach as the following: "...Turkish territory now expects to have masterpieces of itself. We are not thrilled by the foreign and decieving buildings that do not fit in our territory. They seem artificial. If it is possible to differentiate a German from a Turk today, it is necessary to separate a Vienna architecture from an Istanbul architecture, from a France architecture, and even a Istanbul building from an Ankara building... Turkish reform architecture will be something different than the old Ottoman architecture. The dome, the angled window of that architecture are now a history with all its shape. There is no turning back in the road to progress. With the experience of the past, old elements, Seljuk and Ottoman motives are seemed to be inconvenient for today.

Similarly, Abdullah Ziya (1932) says: "The real artifact is not the immitation of the past nor obeying it. The real artist is that who sees the tastes of the society and creates them. The immitated 19th century architecture is dead."

Industry-dependent urbanization and squatting

Since the beginning, industry has been a tool that promotes urbanization and that transforms urban space, in the hands of the statist policies. As a regional policy, especially in small and medium sized cities, the factories opened by the government triggered population accumulation. However none of these cities was able to compete with the magnetizing power of Istanbul. Particularly in 1950's, two basic aspects were effective on the regeneration of space: One was the industry-dependent immigration to Istanbul and that the strengthening of highways. The other one was the squatter's houses of the working class. These aspects chose their places in space by following the Industry Plans, which were applied after Second World War. All of the masters who participated in the process of the planning of Istanbul marked Haliç as an industrial area. In this way, Haliç, which was started to be industrialized since Ottoman times, transformed into an industrial area in the Republic times with the influence of Prost plan.

The special zoning relief for Ankara, which was issued in 1947, spreaded to the country after a year. Populist policies expedited the transformation of cities to shanty-towns. This arbitrary policy of the State is told by Saran (1972) in his article as the following:

“Here (Zeytinburnu), the first shanties were constructed on the side of the roads. At first, the gendarme was a little bit confused towards this issue, but later on, as the number of these buildings augmented, they had to interfere. First, the prefect and then the governor was informed. Although the governor had an attempt to demolish the constructions, he was not successful. Still, the shanty neighborhood was surrounded with the order of the governor and there was not even left water to drink. 1947 was full of fights between the gendarmes and the crowd. In 1948, it was announced to the crowd both in text and in audio, that all the shanties would be demolished on Sunday. The crowd was terrified. While the crowd was looking for a consult, administration of a newspaper advised them to go to Büyük Millet Meclisi Reisi (The Head of the Council of Nation, which was then in Istanbul. A council consisted by the preeminent figures of the shanties went to the Head’s house to convince him to visit the area. The crowd welcomed the Head of the council who went to Zeytinburnu, crying and miserable. The car of the Head did not go into the area really, because it was very muddy then. The Head promised the crowd to not destruct the houses, and a couple of days later the news were official and announced on the radio.”

In Turkey, one of the main problems about shanties is the ignorance of public institutions when approaching the problems thoroughly. In 1964, The National Council of Turkey Republic was proposed a law, regarding the development of shanties under the control of public. In this proposal, it was foreseen that on the lands belong to municipalities, immigrants in the city would build shanties under the control of the technical staff of municipality. In this way, they hoped that the housing problems of people with low income would be solved, and the State would be prevented from losing prestige because of demolishing the shanties. However, this proposal did not regarded positively by the parliament. Members of the Parliaments did not like the idea of labeling people as squatters. (Heper, 1978). Actually, as well as the country did not have an obvious immigration policy, it did not have an experience of shanties neither. In fact, the Minister of Interior found it “positive” that the poor people were solving their own housing problems by themselves. He said “with time, these people will be shown new places and get out of shanties, and in this way they will clean the aspects that disturb the aesthetics of the city, but for now the shanties provided a need.” (Şenyapılı, 2006).

To sustain its political existence, Democratic Party kept supporting the agricultural regions, which put the city workers in difficulty. This bottleneck of city economy was in the core of the plan of development policies. After the *coup d’état* in 1960, during the imported substitution industrialization process between 1960-1980, Development Plans were an important base for the State to plot its ideology over space. The number of 78 thousand shanties in 1962 augmented to 195 thousands after 10 years. At the same year, 40% of the population consisted of squatters. The Shanty Law, which aimed to regulate this process was issued in 1966. In 1970’s, besides those on the treasury lands, people started to build shanties with title deeds in the agricultural areas outside the municipality lands, away from any kind of regulation.

However, a strong authority over the shanty areas was not established for many years. When the rapidly urbanizing rural areas started to be insufficient to provide the needs of the poor, the State, who was incapable of obtaining authority over a stable city, decided to embrace a strategy that limited the State with a national frame, by leaving the town a little bit. (Tekeli, 1998) Besides the rapid on-going squatting, another reality that changed the shaping of space was the apartments in the planned areas. (Figure 10, Figure 11).

Highway centered regeneration

The social class basis of the Democratic Party, which was in authority in 1950, was the alliance of the mercantile bourgeois and the large land owners. (Oktar, Varlı, 2010). In fact, Menderes trusted in this alliance so much that he once said: “*As long as the peasants are with us, how much are the ideas of Istanbul intellectuals worth?*” (S.P Huntington and J.K Dominguez, transferred by: Oktar, Varlı, 2010). Furthermore, the Head of the Democratic Party Adnan Menderes, who embraced the idea of a liberal and externally open economy, focused more on

highways as a response to the incoming Marshall helps. He also interpreted metro as “*It’s a wasteful investment under the ground.*” Highway policies of Menderes evacuated the old city patterns and created new, rigid spaces. (Figure 12, Figure 13, Figure 14).

One of the most important progresses in the regeneration of Istanbul is the construction of Bosphorus Bridge. The bridge shaped the city macroform by being the spine of the town (Figure 15).

Figure 14: The construction of Vatan Street (source: İAM Archieve).

Figure 15. Construction of Bosphoros Bridge (source: mimdap.org).

Mass Housing Projects:

In 1950's, there were two important mass housing project experiences, regulated by the State. Real Estate and Credit Bank was the main character of the process. Koşuyolu, Levent and Ataköy were the first modern regions of the mass housing projects, created for the low middle class. Koşuyolu Houses were built by Real Estate and Credit Banks in 1946-1962 (Figure 16).

Consisted by the 400 houses, the first part of the houses were started to be built in 1947. In 1950 1. Levent was completed (Figure 17).

Ataköy Houses, started on the expropriated area on London Asphalt by Real Estate and Credit Bank, was finished in 1955. (Figure 18, Figure 19).

Local elections in 1973, a right-wing Party in the center for the first time, left-wing Parties in big cities, and interference in city space weakened the impact of the center. While utilizing guiding aspects, the social democrat municipality that came out of this experience started to regard these innovations and the decisions of the development of city, as tools. The guiding and encouraging understanding of municipality that embraced simultaneously with the rest of the world, also brought regulation function of the municipalities in 1970's. This regulative understanding gave birth to Fordist approach of municipalities. Innovations of the municipalities in first mass housing were a big step in terms of the interference of local, instead of central in the cities, and also symbolized an innovative local experience, which gained power against the central authority. In short, with the new Republic, the State who made a big impact on city space and its regeneration in early times changed its approach, and –for some time- agreed to stay behind the local. However, the slogan “we need rice not plans” hinted the special policies of the State in 80's.

Neoliberal period

The process of postmodern organization caused Turkey to embrace a new urbanization policy. One progress that created the basis of this policy was the *coup d'état* in 1980. After the coup

d'état, 1982 constitution came into force. In 1983, a new Cabinet that fit the privatization trend of Europe and America was created in 1983. Then, basic laws that created the basis for the regeneration of city space came into force one after another.

Figure 16. Koşuyolu Houses (source: wowTURKEY.com).

Figure17. Levent 1. Stage Houses (source: wowTURKEY.com).

After the 1. Stage, 2. Levent in 1951, 3. Levent in 1952 and 4. Levent in 1960 was made.

Figure 18. Construction of Ataköy (source: wowTURKEY.com).

Figure 19. Ataköy Houses (source: wowTURKEY.com).

Although 80's were the years in which the basic laws of the city were written, those laws needed approximately 10 years to be applied by transforming the space. Even though policies were embraced simultaneously with the rest of the world, it was going to take time to realise the observable effects of the legal reconstruction. Anavatan Party, with its Liberal-conservative policy, opened the way for city innovations and the transformation of resources of center into investment. After the cities became the center of the capital accumulation and the rent became important for the capital accumulation, private capital started to participate in its direct sanctions on the space (Sancar, www.ozgurlukdunyasi.org).

The way to work with outside capital was opened in those times. Welfare policies left its place to innovative and operator municipalities with the augmenting liberal values.

As it is in the West, 1980's were the years in which the decentralization became more popular and the local government gained power in Turkey as well. The reason for that is mostly the convenience of the negotiation and sharing on an area with local government. In this period, in which the 17 zoning relieves were in progress, the space generation in Istanbul, like in other cities, occurred as the shanties transformed into apartments. The city lost its empty lands quickly. In mid-80's, when Beyoğlu Municipality did not give license for the Gökkafes project planned to be made in Dolmabahçe, central government gave housing permission to Ministry of Public Works, and in one night the border of the strict of Gökkafes was changed and transferred to Sisli Municipality.

In 1989, with the construction of 2. Bosphorus Bridge, and with the neighbor roads opened to service, the shanties were transformed into apartments in first Hasköy, Kağıthane, Caglayan, Gultepe, Ortabayir, and then Sarigazi, Samandira and Sultanbeyli (Figure 20).

In 1980's, Head of the Municipality, Bedrettin Dalan, used the slogan "I'm going to make Haliç as blue as my eyes." to promise the crowd to clean Haliç, which was highly polluted because of industrialization. Indeed, he both worked for the deindustrialization of Haliç by cleansing and rendering Haliç to be used for recreational purposes, and for the Istanbul traffic by making a "scalpel operation." In historical Taksim district, he opened Tarlabası Boulevard, which was a very controversial project for demolishing numerous civil architecture artifacts. In that period, the cases of the profession chambers were lost due to the "superior public interest" verdict. Whereas, Haliç shore was cleansed from industrialization and there was a green corridor created along the shore (Figure 21, Figure 22, Figure 23).

Figure 23. Tarlabası Destruction (source: www.arkitera.com).

In early and mid-80's, the difference between the two development plan, the difference between the perspectives of welfare State and neo-liberal State on space could be seen clearly. 4. Five Years Development Plan covers the years 1979-1983 says: "City lands were subjects of the private ownership. Thus, all special regulation attempts that involve the solutions of the problems in housing plans, which is one of the basic tools of urbanization policy, are insufficient. 5. Plan covers the years 1985-1989 was concentrated on current illegal constructions and services for shanties, and on improving them.

Post-2000 Period

A situation like the coup d'état and post-coup d'état reconstruction was repeated in 2000's. Justice and Development Party, which was born in the conservative-liberal and had a strong base, gained a success in the central and local governments, and on a large geography since the elections in 1994. The most important dynamics that shaped the period was the increasing demands of the global capital and the Marmara earthquake in 1999. Laws that are issued one after another and attempts for institutional reconstruction made the power of central authority on the regeneration of space clear. Contrary to 80's, the central authority had the control of the negotiations and the important area decisions.

In these times, Istanbul was assigned to foreign investors and strengthening big construction companies. According to the laws that created the basis for regeneration, first the historical areas and then the shanty areas, and then the shore and forest areas took a step through big projects in the regeneration process. 3. Bosphorus Bridge, Sulukule and Tarlabası Renewal Projects, Ataşehir Finance Center Project, Galataport, and other cruise shore area regeneration projects started to re-shape the city. Actors of the process were more compared to those of earlier periods: starting from 1994, NGO's took more roles in the participation mechanisms and the private sector shaped the process more strongly compared to 80's.

In the post-2000's, the role and the capability of local governments gradually reduced. Whereas, the central government transformed into an innovative contractor to reconstruct its content to strengthen its capability, with institutions like Environment and Urbanization Minister and Mass Housing Administration. This reconstruction overlooked all the actual plans and represented a projet-centered mentality –one-man governance-. Kanal İstanbul project, also known as "Crazy Project of the Prime Minister", started by overlooking the agricultural areas, natural registered areas and areas at the risk of natural disasters, and also ignoring the advices of the masters. The effects of such a situation could be seen in many examples. Journalist Necati Doğru mentioned 3. Bridge as the following in one of his articles: "I've asked to the Mayor, Kadir Topbaş; "...the feet and the direction of the third brige, which will affect the city you're governing in many aspects are determined by Ankara who sees the city from a helicopter. Does it sound right?" Kadir Tobaş answered me. "No, it's not." and he claimed: "The direction won't be determined by the helicopter. In the plan that he made for Turkey, the Trasportation Minister developed '3. Brige Project Proposal' for Istanbul. This project developed by the Minister will be evaluated by Istanbul Metropolitan Planning Center in terms of 'compliance and land usage analysis', and then the exact direction will be presented to Istanbul Metropolitan Municipality Council."

The effect of power and the capability was clearly obvious in Taksim Gezi Park events which took place in the world press. Who came face to face with the society were just the Prime Minister and the Governor. 2000's has witnessed that the architectural design has been strengthened by the symbols of power. Ataşehir Mosque and Çamlıca Mosque which is planned to build on the top of Çamlıca the most striking examples of this process (Figure 24, 25).

Figure 24. Ataşehir Mosque (source: www.yapi.com.tr).

Figure 25. Çamlıca Mosque (source: www.yapi.com.tr).

Evaluation

As a result, it is not a new experience for Istanbul to witness the reflections of the ideology of the State on space. Plus, this experience transformed the judgement verdict into applications made by overlooking even the international institutions. Spatial verdicts were made with the “one voice” of the center, and the term planning stayed behind in the regeneration of space. The appearance of political Islam in public space augmented with symbols and signs. In Turkey, the appearance of Islam in public is also a part of a politically organized social attempt to create an Islamic society system to create a middle-class “ethos” (Saktanber, 2007). This process can be summarized with the following chart (Table 2).

Table 2. The role of the State and its ideology in the regeneration of urban space

Period	Policy	Actor	Regeneration of Space	Tools	Situation of the State-Paradigm
From the early Republic periods to 1980's	Rural Policies	Central Authority	İdeal Republican Village Village Institutes, Public Houses	Legal and Institutional Reconstruction Planning Development Plans after 1964	Pluralist - paradigm
	Urban Policies	Central Authority	Transition from Organic Pattern to Rigid Pattern Evacuation of the Past Large Boulevards Ceremony Areas Public Buildings Theatres, Cinemas, etc. Cultural Buildings Squatter areas		
Neoliberal period	Urban Policies	Central and local authority	<u>Before 1990's</u> Squatter areas Unplanned construction Bridges	Military coup d'état Globalization Legal and institutional reconstruction	Class-centered paradigm
		Military between 80-83 Speculators	<u>After 1990's</u> High office buildings Huge shopping centers Mass housing	Development Plans Major Projects Privatization Zoning Relief Earthquake	
2000 sonrası dönem	Rural Policies	Central authority	Transformation of rural areas to urban areas	Legal and Institutional Reconstruction	Governing paradigm
	Urban Policies	Central authority Private sector NGO's	Transformation of urban areas Skyscrapers Huge shopping centers Comprehensive luxury housing projects Icons and symbols of political Islam	Major Projects "Crazy" Projects Privatization

Abstract. *Social and spatial complexity is the most outstanding feature of contemporary Rome (IT) metropolitan core, one of the main touristic destinations in Europe for its touristic attractions and a pluricultural metropolis, one of the main immigration gateways to Western Europe. Space Syntax methods and tools were applied to describe and analyze Rome (IT) spatial network measuring accessibility – connectivity, integration - segregation correlated to movement potential and fluxes probability. Data was empirically collected for Trastevere and Esquilino neighborhoods, providing a configurational explanation for foreigner's locational choices. We target to describe sociospatial practices enabling spatial governance and its impacts on co presence diversification and ethnic centralities. Our hypothesis is that urban grid morphological differences play a main role in fulfilling these users' expectations towards interaction with locals and mobility and can explain social appropriation of space transformations, triggering gentrification and significant co presence processes from which emerge enclaves and interethnic neighborhoods. Our purposes are: (1) to describe and analyze Rome city core spatial street network, applying Space Syntax tools and modeling methods; (2) to correlate route choice probability at local, global and metropolitan scales to immigrant and tourists spatial practices and locational choices; (3) to identify relations between spatial configuration and ethnic groups spatial agency; (4) to analyze users groups sociospatial strategies impact on neighborhoods' spatial lives.*

Key Words: spatial configuration, Rome (IT) city core, spatial governance, neighborhoods transformations; foreigners' routes, significant co presence

Foreword: Rome, the intercultural metropolis shades plural cities

Social meanings for place and space are not uniform and these are old news for the city of Rome (IT), for centuries a pluriethnic city, the earliest Western / Mediterranean Empire Capital. Italy has been an emigration country for about 100 years. From 1970ies on, it became a major *off-CEE* immigration attractor, drawing African, Middle Eastern, East European and Far Eastern steady foreign fluxes. Urban life cultural plurality was enhanced by *brain drain* processes, endogenous migrations (S-N) and tourism intensification. These processes impacted Italian cities strongly, causing the reorganization of local social relations and neighborhoods' spatial lives transformations with impacts on co presence, natural movement and land use patterns related to migration, touristic fluxes, globalization (*grassroots specially*, Appadurai, 2000), European territorial reorganization and contemporary diasporas from which emerge new forms of citizenship and group affiliation. That frame Italian urban planner's concerns on cultural heritage, socioeconomic integration, neighborhoods' transformations and residential segregation

and were summed on MEGARIDE / European Urban Directives Chart (1994¹¹⁶) towards interethnic integration and UNESCO *MOST* meetings (1984) addressing tourism impact on European metropolis. Their concern is that “cities might provide diversified places to fulfill the needs of its citizen’s majority and different ethnic groups, understanding diversity and alterity as a valuable social capital linked to urban development positive standards” (Beguinot, 2009, 30-2), adding that the contemporary interethnic city must be open, equalitarian, intelligible and sustainable, goals drawn from sociospatial qualities.

Rome is exemplary of large scale social processes ignited elsewhere and spread by networks informing foreigner's locational choices which modify urban dynamics, promote selective reconfigurations on interface patterns between local and strangers, movement and co presence, impacting sociospatial integration. Its metropolitan area is a patchwork of self-contained, fragmented, discontinuous and morphologically diverse urban sprawls that challenge its core spatial structure resilience and compacity. These relate to the way in which city core public places are socially appropriated by its *users*.

Space Syntax (Hillier & Hanson, 1984) methods and tools describe space as a system of constraints and potentials which define social interaction patterns through local (inhabitants) or global (strangers) control. Foreigner's collectives diversified co presence or ethnic segmented gathering practices suggest that *strangers* (Hillier & Hanson, 1984; Vaughan, 2007) unfold subcategories that capture the spatial system morphological properties to fulfill their expectations towards socioeconomic integration, interaction with locals and mobility.

Configurational analysis depicts social behavior from spatial patterns inequalities driving movement and co presence potentials. Provides evidences to analyze how foreigners experience the city, where foreigners presence is strong enough to provide places a new identity and attribute meaning for conflictive social relations from the way in which control over spatial structure privilege inhabitants or strangers, enhancing social boundaries or easing their transition from one status to another (Hillier, 1993). These processes drive a selective reconfiguration of land uses and *significant co presence* emergency according to cultural group's autonomy and bordering practices (APPADURAI, 2000). While in site, the group might regulate co presence in the area, a process known as *spatial governance*, reinforcing fluxes to collectively built centralities in a way that can affect other people behavior and assign these places symbolic meanings.

Our targets in describing Rome configuration are to provide sociospatial evidences that explain differences on foreigners' locational choices for gathering and the emergence of specialized centralities leaving for further research the intertwinements between urban sprawl, spatial segregation and these groups social reproduction. We focus on two neighborhoods - *Trastevere* and *Esquilino* - supplying empirical evidence of foreigners' - tourists and immigrants spatial behavior in order to test our hypothesis and analyze the correlation between spatial variables and co presence patterns (Hillier, 1999). We aim to contribute to the discussion on interethnic / pluricultural relations within European metropolis and their changing human landscapes.

We justify our methods by the premises: a) the neighborhoods cluster high land uses and attractors related to foreigners co presence giving emergency to specialized functional centralities that act as *place signifiers* - *Chinatown* (MUDU, 2006), touristic ghetto-, b) "*inassimilable ethnic groups*", even when represent an unexpressive population share (2% Chinese on Rome population), a lot less than the impressive amount of tourists (up to 50% of the city's population) that flood the city every summer, monopolize urban planning debate; c) Tourist herds' definitely impact spatial life locally and ignite long lasting transformation processes such as gentrification ones; d) meanings given to co presence and interaction system based on avoidance / gathering (Holanda, 2010), are driven by subjective values affected by alterity and otherness notions (APPADURAI, 2000).

¹¹⁶ Beguinot, Corrado (ed.) 1995 Carta Di Megaride 94. Città Della Pace-Città Della Scienza. Napoli: Aa.Vv, Napoli.

We focus on immigrant and tourists /short term resident's different goals towards spatial integration, their sociospatial logics and the phenomena described above. Foreigners control over space might relate to mobility, accessibility and functional centralities and the way in which socioeconomic integration is achieved. It might be through individual entrepreneurship and community agency or through stable gathering places where renew and spread supportive networks providing landmarks for shared social and cultural practices and work opportunities information diffusion.

Alessandria (2004) findings on foreign workers gathering practices depict their goals to minimize suburbanization, residential segregation, group spatial dispersion and social marginalization negative integration effects and to face social discrimination through visibility strategies and cultural identity affirmative behavior performed in central public places. Their locational choices contemplate good accessibility to group's main clustering zones and transport / commuting nodes stable references, both vital for social network stability. That is why *betweenness* centralities matter (Hillier, 1999).

For tourists, accessibility, connectivity and straight forward routes to their hotspots explain their locational choices, since becoming local is not among their priorities. Navigating a foreign city where they won't stay long enough matter: through movement and *walking distance* matter. Tourist's information networks produce and are feed by stable spatial references which, in turn, promote functional clustering and specialized centralities.

Our hypothesis is that foreigner's locational strategies are intertwined to the spatial structure, driving the election for gathering places according to collectives' social expectations towards interaction with locals and among themselves and whose regards towards spatial and social integration are built in different ways. For these reasons, addressing foreigner's co presence as a relational byproduct of spatial patterns differentiation grant meaning to their spatial strategies, to Rome spatial syntax.

Rome metropolitan core spatial network: the analysis and its goals

If contemporary social relations are built from and through movement potential rather than territoriality, navigational information depicted from the spatial network might enforce social boundaries, since movement is a *kind* of amorphous and dynamic power driven by potential connectivity and node control. For that we provide a configurational description applying three Space Syntax modeling methods - Axial, Angular and metric Radius (Hillier & Iida, 2005) from which depict the morphological properties that enable us to analyze strangers subcategory (Hillier & Hanson, 1984) - tourists and foreign workers - spatial behavior.

Rome city core was decomposed into a one-dimensional graph, the axial map (Figure 1) depicting its spatial network (Hillier, 2013) modeled using *depthmapX* software© (Varoudis, 2009). The mapping boundaries were established by spatial barriers and urban grid discontinuities surrounding the core: geomorphic barriers (rivers and hills), main *ring roads* and railroads, institutional / archaeological compounds, urban grid discontinuities (Figure 1).

Hillier & Iida (2005) definitions that integration is topological closeness, Choice is bridging or accessibility and Segment Analysis is connectivity potential modulated by cognitive information ponder correlations for foreigners spatial behavior within the city core. If *integration* (R_n , R_3) measures potentials and *choice* probability, we might compare them to empirically collected data on ethnic and tourists clustering and spatial practices (Hillier, 1999).

Axial analysis focuses on topological integration. Urban grids deformation degree is measured by continuity, linearity, connectivity and control potentials between its parts (Hillier & Hanson, 1984). Local and global Integration (HHR_n/R_3) inform the potential for natural movement and co presence within the urban grid. Analysis enable to explain group clustering choices towards interaction with inhabitants and social boundaries emergence through groups' most instrumental exercise of power: control over places. Route choice (HH_{Choice}) depicts the shortest paths providing best accessibility between all parts of the system, attributing the most

probable used routes an iconographic hierarchy ranging from red to blue, allowing to evaluate fluxes probabilities along routes.

Figure 1. Axial map of Rome city core (Andrea Braga, Fabio Zampieri & Daniela Reckziegel) on cartographic shapes mosaic (© Università La Sapienza di Roma, Data Library developed by G. Longo), recomposed by Zampieri. Cartographic source: Lamco S.r.l; Catizzone, A., Regione Lazio, Carta Tecnica Regionale, volo 2002, restituzione, 2005. Costanti di transito da Gauss-Boaga a U.T.M. ED50, Elemento n°37406(1,2,3,4).

Spatial structure ringness strength equals to weak synergy between local and global spatial patterns, differentiating the ways space is socially appropriated (idem) underlying the notion of meaningful co presence (Hillier, 1999a): control and bordering of public spaces, in short spatial governance, for which avoidance and gathering modify the notion of co presence as the “unaware presence of strangers and dwellers in the same convex space”.

Segment modeling transforms axial lines into nodes according to the deflecting angle of its connections to other segments and captures cognitive information implicated in navigation; what is perceived as spatial and visual continuity /along a route (SegInt) modifying deepness topological structure to depict more accurate fluxes probabilities . The analysis consider *betweenness* centrality on different metric radius (SegChoice 500m, 1km, 5Km) to evaluate the role route choice has on the emergence of specialized centralities as a function of local, global or metropolitan movement.

These provided configurational evidence for foreigner's successful exploitation of the urban grid morphological properties according to their different objectives towards integration in correlation to their sociospatial behavior of unexpected centralities “which can only be explained beyond street grid configuration, through navigational patterns” (Hillier & Iida, 2005).

Rome city core configurational description: touristic and immigrant co presence and routes

Axial and Segment modeling's (Figure 2) depict *Corso Italia* (*Cardo – Decumanus* system) as the most integrated axis within the city core, a linear centrality at global and local scales. It stretches from *Piazza Venezia*, the gateway to *Foro Romano*, to the end of *via Flaminia - Foro Italico*, connecting both Ancient Rome ritual centers, defining the main route through the old city core and to its expansions beyond *Tevere* river (W,N), *Pincio*, *Palatino* and *Quirinale* hills (E, S) through two ceremonial plazas – *del Popolo* (N) and *Venezia* (S) both are encircled by main traffic connections.

Axial Choice (HH) depicts quite accurately routes from *Piazza del Popolo* to *Vatican city*, *Castel Sant'Angelo* and *Trastevere* (W), main touristic attractions. *Via Flaminia* (N) stretches *Corso* integration on a single axis towards Imperial archeological sites and newer developments (*Vila Olimpica*, *Parioli*). From *Piazza Venezia* (S), *Vias dei Fori Imperiali* (*Colosseo*) and *Del Teatro di Marcello* enclose archeological monuments (*Foro Romano*, *Palatino*, *Circo Massimo*) connected by *via Appia*.

The *Corso* integration / connectivity robustness turns it into the spatial network central node: it controls routes / touristic paths through the old core (*Pantheon*, *Piazza Navona*, etc.) and to core surroundings. It also contributes to exploring the scenic and picturesque character of the area by providing visual fields which improve navigation while wandering around: *Corso* is a compass for wanderers venturing into the old core allowing strangers to regain control over navigation, out of the labyrinth.

Comparison between axial local / global integration evidenced secondary functional centralities subjected by the *Corso* integration / connectivity robustness which bounds different phases on urban evolution. On its Western side, spatial system is deeper and less intelligible due to strong grid deformation denoting local (inhabitants) control over the whole city core.

Corso (W), *Via del Babuino* (E) and *via Nazionale* (S) form a triangle of shallow, well integrated and connected axes bounded by *Pinchio* hills / *Villa Borghese* (E). Its deformed orthogonal grid has better global integration that grants strangers control over this part of the system. It defines a perimeter for Rome's symbolic and functional centralities and tourists stroll freely from *Piazza di Spagna* to *Fontana di Trevi*, *Campidoglio* and *Quirinale*.

Axial Choice depicts radial axes connecting urban expansions to the *Corso* formed by Ancient Rome roads system that structured its regional territory (*Salara*, *Ostiense*, *Casilina*, *Portuense*, *Tiburtina*) and ritual periphery (*Cimitero Monumentale*) outside the city walls. The longest E-W axis linking *Piazza di Spagna* to the *Tevere* banks / *Castel Sant'Angelo*, across the *Corso* with higher integration measure is *Via Condotti*, a reference for tourists and shoppers.

The triangle stretches south from *Piazza Venezia*, linking *Palatino - Colosseo* / *Colle Oppio* and *XX Settembre / Nomentana* (S) / *Via Cavour* (E) connecting peripheries (E) and 19th century monumental sites. The city's main commuting node, *Termini* train station is the far vortex (E) beyond which global integration fades, bounding the compact city and reinforcing sprawl discontinuities through superimposed spatial barriers.

18th and 19th centuries changes urban grid expansions turning linear functional centralities into distributive through the fusion between orthogonal and radial systems, distributing global integration.

Metropolitan sprawl follows residential segregation patterns for lower or upper classes indistinctively captured better through Segment Analysis. Spatial network global integration (SegInt) is more robust than axial, pondered by connectivity that highlight large scale circulation hierarchies (ring roads) as preferable routes surrounding the city core, outside the walls connected to commuting nodes (train stations radial roads systems). The measure depicts routes from peripheries to the centre and between neighborhoods, around the core forming a ring road system connecting each part of the metropolitan discontinuous sprawl. Their efficiency in taking vehicular movement to the old core perimeter change the ancient centre-

periphery global choice radial structure into a deformed wheel, improving the urban grid ringness which, in turn, improve connectivity and accessibility between system's parts.

Figure 2. Rome axial (HH) and angular (Seg) modeling DepthMap aided by Claudio Ugalde

Changing metric radius to segment choice modeling (Figure 3) enabled to depict the urban grid changes following sociospatial transformations to the city core (500m) spatial patterns such as late medieval segregation between civic (Campidoglio) and religious (Piazza San Pietro), their connection through Corso Vittorio Emmanuele (W) and consequent N-S old core divide into unbalanced halves, that produced a popular, pollute and peripheral southern centrality (Campo di Fiori).

Figure 3. Route Choice system Axial and Segment modeling (Claudio Ugalde). Route from the Old Core to Trastevere is highlighted in red/yellow for 500m radius.

Segment Choice for 1Km radius (Figure 4) highlights the radial system linking the city core to its expansions and another commuting node at the end of *via Flaminia*: *Piazas Mancini and Apollodoro*, both functional and ethnic centralities to immigrant domestic help scattered along upscale neighborhoods (*Parioli*), referential to South Americans gathering practices. Expanding radius to 5km, secondary and local centralities emerge along routes connecting suburbia to the core (E-W) where middle class developments abound. Street markets and immigrant significant co presence on public squares along transportation main routes and commuting nodes evidence their preference for highly accessible and visible gathering practices targeting alterity affirmative behavior as their sociospatial integration strategy and endogenous bond renewal.

Comparing Choice system, axial and angular, we find out coherent morphological boundaries to residential developments provided by main axes capturing both configurational and functional centralities. That indicates that local centralities tend to linearity, shared by more than one neighborhood, what reinforces connection and integration between different socioeconomic clusters. Roman peripheries are highly segregated, but well connected to the core, a possible explanation for tourists keeping their ground near the core and for immigrants choice of gathering places (Figure 4).

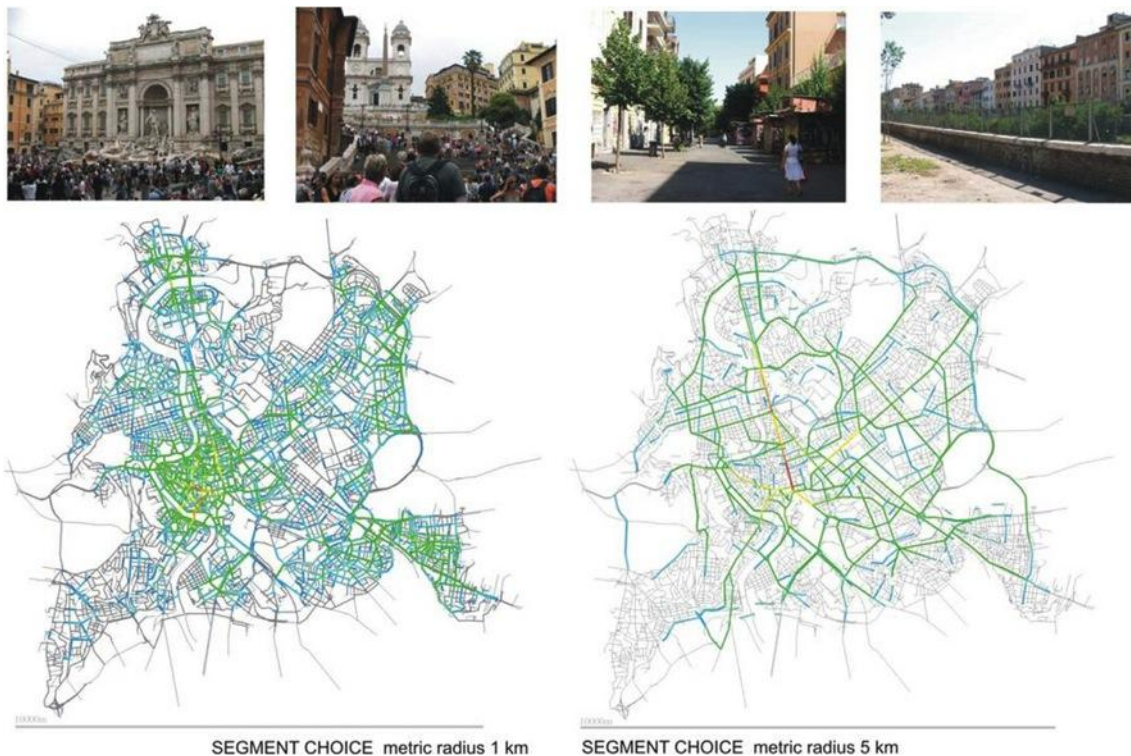

Figure 4. (Above, left) Fontana di Trevi and Piazza di Spagna: two main touristic hotspots located within the Old core higher Axial Segmented Integration area, always full of tourists; Circunvalazione Casilina and via del Pigneto (right), one of c Rome oldest suburbs (SE), going through a gentrification process. Photos: Andrea Braga, 2011. Below: Segment Choice 1 and 5 Km radius (Claudio Ugalde). The short route in orange (W) links Largo Argentina and Campo dei Fiori to Trastevere (right). 5km radius depicts routes linking Termini to SE suburbs. The two main axes (NE) are via Salaria and Viale Libia, enclosing newer residential developments. Lungotevere main vehicular route encircles the old city core. The Corso segment with intenser fluxes cuts the old core.

Strangers in paradise: spatial qualities turned *Trastevere* into a tourists' enclave

Trastevere (W) was one of the earliest Rome urban expansions (13th century). A walled medieval compound built on rural land across the *Tevere*. The spatial system is deep, poorly connected to its surroundings, a quality reinforced by topographical boundaries (W). Large densely built blocks and small scale public spaces produce a series of short axes indicating local inhabitants control and spatial solidarity. In 1980ies it resembled a *typical italian village*: neighbors chattering through open windows and laundry lines crisscrossing narrow streets (Figure 5).

Control over space being one of the main forces driving the organization of social relations, enhance different spatial strategies to fulfill foreigners purposes *locally*, transforming not only these places social lives but also Rome population imaginary over them. Final stop for main touristic routes, *Trastevere* is a gated community since its earliest days, converted successfully into an American *expats* enclave.

The neighborhood gentrification process was anchored by the opening of three USA college branches focusing *study term abroad* that turned long term tourists into short term residents, enabling their local control over space. *Trastevere* social and spatial life is turning into a simulacrum through drastic changes: dwellings converted into short term rental unities / student hostels, local shops replaced by restaurants, cafes, tourist shops, meeting new inhabitant's needs.

SegChoice (radius 500m, 1 Km) fluxes probability is coherent with empirically observed movement and co presence along routes irradiating from *Piazza di Santa Maria in Trastevere* to main hotspots on the old city core, providing strong spatial reasons to become a tourist's enclave. Local control is strong; it is spatially segregated from its surroundings but well connected to points of touristic interest; conforms to *campus lifestyle* with its cafes, restaurants and "student dorms" that enable this *expat* community to experience Rome without being infatuated by metropolitan life.

Retracing the highlighted route choice system back to *Trastevere* (Figure 5) reveal that intense fluxes are more probable along the circuit connecting *Piazza Venezia*, *Largo Argentina*, *Campo di Fiori*, *Ponte Sisto* to *Piazza Santa Maria in Trastevere*. It explains why we were fooled by *Trastevere* axial segregation, when empirical evidence was counterintuitive: shorter and straight routes connecting city core attractions to the neighborhood justify its touristic attractiveness. *Trastevere* is at *walking distance to / through* main Rome touristic attractions.

A group strongest potential mobility might weaken other group's chances towards the same opportunities. Tourists spatial governance empower themselves towards local control over movement and route choice discouraging diversified co presence. We ask ourselves if their spatial behavior weaken Rome inhabitant's ties to such places, changing their identity locally and globally from which emerge new kinds of specific and exclusive centralities.

Tourists tend to limit interaction with inhabitants to a minimum. Axial integration is less important to them than route choice and *betweenness* centrality. Spatial segregation might become an advantage as long as the potential enclave is strategically located and connected to / connecting points of interest. Clustering provides safety and enhances significant co presence in a highly accessible spot. *Trastevere* sums those spatial / instrumental qualities money can buy; therefore Americans spatial governance is noticeable here. No wonder the neighborhood plays a special role on Woody Allen's *To Rome with Love* (2012).

Strangers meet in paradise: spatial reasons that turned Esquilino into an interethnic neighborhood

Esquilino is considered the most globalized, cosmopolitan Rome neighborhood and a successful interethnic community case, even if official data (legal immigrants, 2010) is only 36% of neighborhood population share. Residents major ethnic groups are diversified: Eritreans, Bangalores, Philippines and Romenians are numerically expressive (7,8% to 5,9%). Other

groups subjected to immigration fluxes aren't dwellers (chinese, polish, africans, indians, afganis) either workers / users of services hub give sense to the statement above. Copresence is defined by interethnic relations giving emergency to special forms of sociospatial and economical integration and place image.

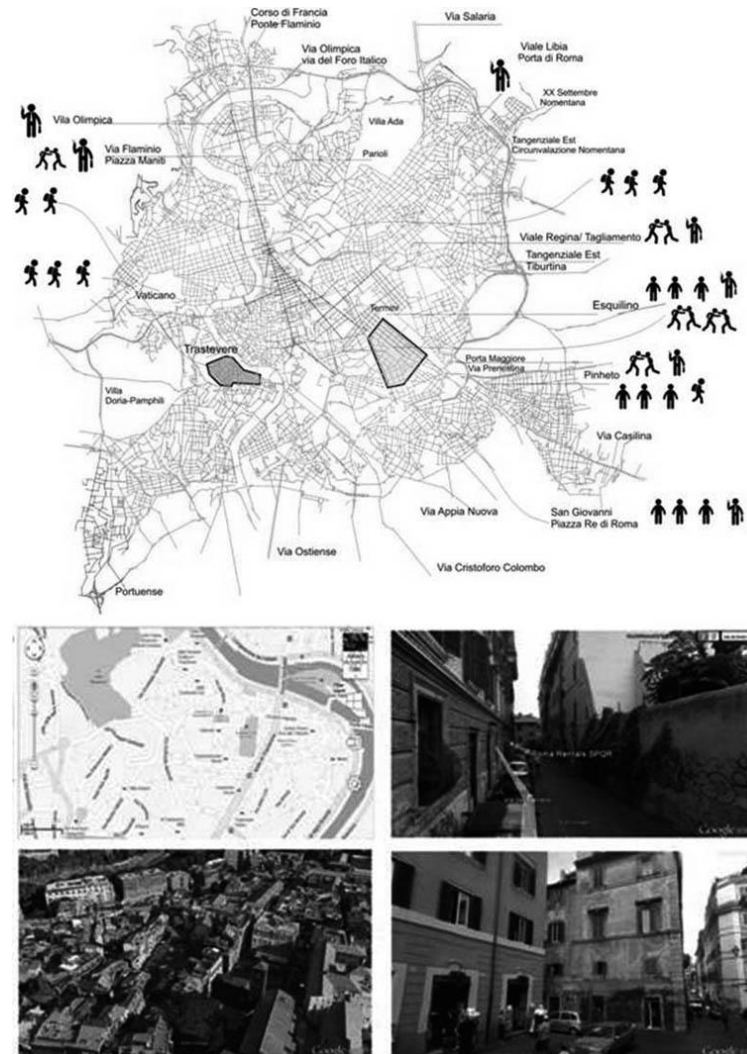

Figure 5. Above HH Integration Rn displaying empirically collected data on tourists (backpack), inhabitants (cell phone) and strong foreign workers movement / gathering (hugging) places (Andrea Braga, 2011). Centre: Trastevere map showing American universities campi and neighborhood landscapes (Google Earth, Street view); Below: Pigneto neighborhood maps and images (images: Google Earth, Street view).

An 18th century urban expansion that changed the city core development E-W along its historical fringes, *Esquilino* orthogonal grid is cut by diagonals spreading from a large scale piazza, *Vittorio Emanuele* (250mx120m) at its geometric centre. Sinergy between local / global integration mesaures distributes control among inhabitants and strangers, symbolic of Italy unification: urban modernization, territorial and sociocultural integration (Aymonino, 1985). Since its once borgeois founding, *Esquilino* is foreigner's territory. Decadent in the eighties, was enrolled on Rome Municipality's *Historical centre renovation plan* (1981-5, SPQR) strategies to ignite socioeconomic changes: *Termini* modernization, urban and environmental

recuperation, street food market (1902-2001) replacement, via GGiolitti extension to *Porta Maggiore* and new functions induction (hotels, culture, education).

Centrality spread easily through the orthogonal grid according to complex dynamics from which an *immigrant centrality* (MUDU, 2006) emerged through ethnic entrepreneurship, grassroots globalization and interactions between sociospatial and political variables and also interfaces between inhabitants /strangers, *italians* / ethnocultural groups, concurrent with italians neglecting the use of public places. Places potential centrality are key in urban transformation processes and to understand appropriation conflicts due to interfaces intensity it encloses, living out of diversification / especialization duality (Hillier, 1999).

Strong spatial reasons lead Esquilino to be known as an immigrant centre (Figure 6), reassigning roles between *local* / *strangers*. Good accessibility and connectivity to immediate periphery potentialize *to* and *through* movement, configuring centrality, in which commercial activity relay, strengthen by monopolist attractors, transport hubs and global integration robustness that meet immigrants objectives towards socioeconomic integration and endogenous - exogenous interface system. Economic variables were low cost real estate; local commerce decay and depopulation that activated ethnic agency promoting complex transformations that unbalanced the once evenly distributed spatial control between inhabitants and strangers, turning the neighborhood into what its shallow spatial structure and its connectivity to peripheral areas allow better: to become a functional centrality, for better or worst. That's why immigrants *occupied* Esquilino.

Figure 6. Top-down left-right: Esquilino and Piazza Vittorio (Andrea Braga, 2011; CRAPSI et al, 2010); Orchestra di Piazza Vittorio (2002): Cultural Hybridism and conviviality in pluriethnic Esquilino (Source: Ethnic newspapers Bellobuono et al. Marino, 2010); Esquilino market (Piccione, 2010); Other images are all by Andrea Braga, 2011.

The context favored ethnic entrepreneurship specialization by branches (LIGHT et al. 2009) summing up to transform the neighborhood's spatial and social lives. Spatial governance emerges from conflictive sociospatial practises and unbalanced control over spatial dynamics attributing meaning to ethnic copresence: Italians seldom gather in public, immigrants do the opposite despite group membership. Ethnicity might be considered spatially built in Esquilino.

Distributive connectedness and accessibility disperse centralities and give way to several gathering places to which groups refer according to their interest, needs and degree of social and economical integration.

Esquilino is a strangers place, its shallowness, accesibility and conectivity attract immigants eager to mingle and integrate themselves into the city's economical and social life. A stable functional centrality confirms its importance in structuring SE urban expansion. Its orthogonal grid provides the fair ground for interaction between locals and strangers. We might risk saying that once in *Esquilino* foreigners feel at home, explaining why the neighborhood is an example of positive sociocultural and economic interethnic integration.

Walking along invisible borderlines: Esquilino spatial configuration, ethnic commerce and plural territorialities

Co presence data collected empirically display main gathering places which support ethnic solidarity networks, enabling us to analyze different spatial strategies operated by immigrants on their locational choices. Addressing foreigner's co presence as a relational byproduct of spatial patterns differentiation provided some evidence to their voluntary clustering at *Esquilino*, appropriated as a metropolitan centrality.

Enclosed by main routes linking *Termini* to Southern suburbs, the area is alive with *to* and *through* movement reinforced by the mere location of this monopolist attractor. Accessibility to the city core, connectivity to surroundings and main metropolitan commuting hubs reinforce its functional centrality and are instrumental to ethnic/cultural groups gathering choices since global integration matters for foreigners. Significant co presence follows criteria related to spatial control: foreign workers might be *inhabitants* if living /working on the neighborhood; or *strangers* who come from afar to socialize or shop. Gathering places vary according to ethnicity, inhabitants / strangers *divide*, integration measures and movement potentials. If the *Corso* axis is where tourists and inhabitant's co presence and movement are evenly distributed, the orthogonal grid integration differences ponder significant co presence (Figure 7).

Via *GGiolliti* / *Piazza Vittorio* Eastside define the perimeter where HHRn is stronger, concentrating most part of ethnic / metropolitan commerce and foreign co presence. HHRn/R3 depicts stronger integration measures on N-S axes. Via *GGiolliti* is the longest and most globally integrated axis connecting to the ring road system (*Circonvallazione Tiburtina, SE*) and captures vehicular movement on the neighborhood periphery. Pedestrian movement is weak beyond *Termini* secondary entrance and ethnic significant co presence is outstanding between *Cattaneo* and *Cappellini* streets, where's a sort of newly *immigrates* service hub (restaurants, call & remittance centers, hostels, DVDs/ newsagents) emerged. The site is easily spotted from *Termini* but secluded from pedestrian movement, on an elevated sidewalk. Around its corners (Capellini /Rattazi) a step deeper, beauty parlors, *International Amnesty* and other legal assistance offices provide refugees / immigrant's social support, services and gathering references, leading us to conclude that this area attracts foreigners *strangers* to the neighborhood, barely venturing far from its boundaries (Figure 5). Co presence is mainly African and masculine and groups are small.

Esquilino food market entrance (*Principe Amedeo*) attracts ethnic restoration and specialized food suppliers to its vicinity, organizing its spatial concentration and spread: Shop management gives sense to ethnic groups gatherings and include travel agencies, call/remittance centers, restoration in the mix. Foreign inhabitant's masculine co presence is high on weekdays, gatherings usually outside small cafes near the market, solidarity built through their trade and gender. Co presence diversification and movement increase on Saturdays, market's grand day, when the whole street turns into a pluricultural and interethnic gathering place. On Sundays, gatherings move to *Piazza Vittorio* where ethnic, gender and age groups have stable meeting points inside and around its limits.

Piazza Fanti vicinity defines the boundary between interethnic *Esquilino* and touristic Rome; from there until via *Cavour* there are almost exclusively hotels, B&B, guest houses and tourism

related services. Around the Piazza, Bangalore jewelry shops and beauty parlors mix with African handcraft, Chinese retail and restaurants. Ethnic co presence is weaker, groups are smaller but spatial governance is stronger, each group controlling small stretches of sidewalk.

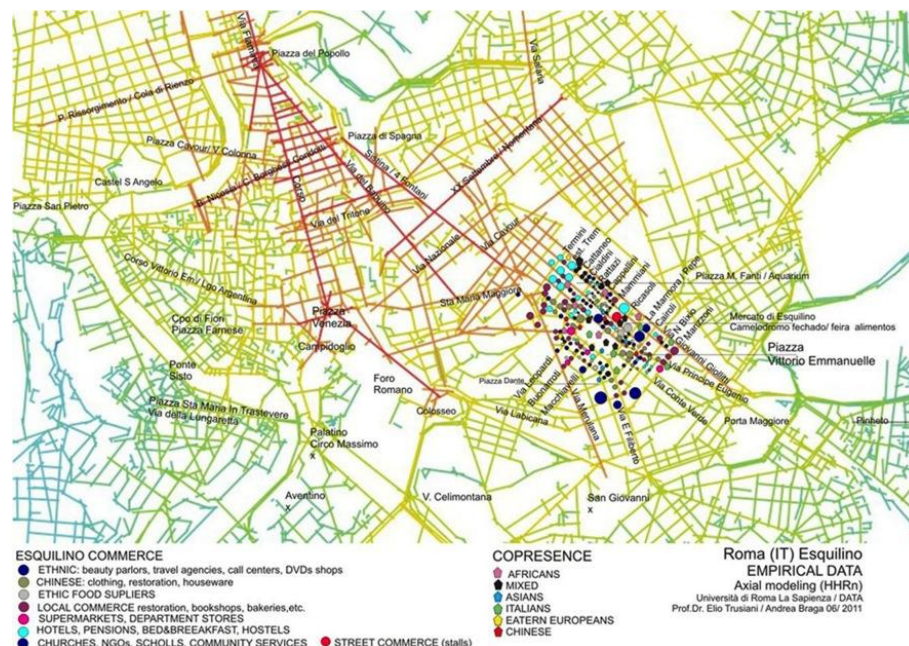

Figure 7. Co presence and ethnic land use labels dispersion in Esquilino (Andrea Braga, 2011).

Via La Marmora block between *Principe Amedeo* and *Piazza Vittorio* is Indian/ Bengali territory where *Bollywood DVD* 's shops, clothing and newsagents draw this group major co presence. Chinese commerce (clothing wholesalers /retail) cluster on *Piazza Vittorio* eastern side, sprawling north along *Napoleone III / Carlo Alberto*, where it diversifies (beauty parlors, ethnics, restoration) and South along *Conte Verde* (clothing), where through movement is intense. *Palazzo del Freddo* (traditional ice cream factory) turned global ironically through Far Eastern franchises, *Mas* department store and missionary churches outstand among Chinese homogeneous shops testifying for previous commercial trends and diversifying co presence.

The Western side of *Piazza Vittorio* is a secondary functional centrality to the city core spreading towards *via Cavour* (N) / *Merulana* (W) with traditional shops still doing business (popular department stores, cafes, clothing, and hotels). Shorter axes perpendicular to *Piazza Vittorio* (W, *Foscolo*, *Machiavelli*, *Leopardi*) concentrate neighborhood commerce (supermarkets, giftshops) but also some ethnic services such as call centers, remittance, electronics, travel agencies and beauty parlors (massage) hidden from main *through movement* routes, but accessible to *insiders*. Streets seem *empty*, large institutional buildings and dwellings predominate, movement and co presence are weak, stronger local control is easily perceived. Foreigners gather on the sidewalks, attentive to people passing by, arousing uneasiness reinforced by the ambiguity of services provided.

Ethnic ommerce is usually placed along less integrated axes. Grassroots globalized business networks nodify along axes displaying better to / through movement potentials. Foreign workers who see themselves as locals gather along most integrated axes. Newcomers tend to gather in more secluded places, meaning axes which natural movement potentials aren't fulfilled, but remain important vehicular routes through the neighborhood, displaying good accessibility and connectiveness locally and globally.

Piazza Vittorio seems to be the boundary between the prevalence of local and global integration and their effects on social and spatial life. On its Western side movement and co

presence are weak, local commerce prevails and ethnic co presence is discrete. On its Eastern side through movement is intense, reinforced by commuting nodes; foreigner's co presence remarkable since integration higher measures favors stranger's control.

Foreign workers mere copresence in public spaces denotes their eagerness for urbanity, attributing meaning to different integration patterns within the neighborhood. We identified three functional centralities based on commercial branches distribution (Figure6): its Northern zone extends city core centrality, taken over by tourism services and commerce; Piazza Vittorio west side a neighborhood centrality punctuated by low profile ethnic commerce and services; and a metropolitan one (SE), sensitive to fluxes through Eastern peripheries, re-built on immigrant/ethnic entrepreneurship. Their superposition plus the configuration potential to fullfil different social agendas feed conflict over space and impacts social imaginary for its spatial qualities resilience that enable profound functional transformations.

Esquilino social life operates between neighborhood and ethnic relations: foreigners can be neighbors according to its spatial integration hierarchy that eases conviviality. Economical decay might be overcome thanks to its local connectivity, global integration, high accessibility and gentrification process ignited institutionally. Its spatial patterns jeopardize coherence between social exclusion and spatial segregation, challenging the political agenda because addresses *new romans* integration to Italian society, which extent and form is molded through spatial integration equal to economic one.

The neighborhood spatial and social life is divided by an E-W boundary, *Piazza Vittorio*: an Eastern *ethnic Esquilino* (Figure 8) and a Western Roman one. *Piazza Vittorio* itself is a frontier zone where spatial governance is negotiated evenly between Italians and foreigners, immigrants and tourists, where different forms of territoriality might be displayed side-by-side. Where foreigner's become *new romans*, where *romans* acknowledge their *otherness*.

Figure 8. ethnic commerce and service on GGiolliti elevated sidewalk and Termini connection to San Lorenzo. Esquilino market surroundings (photos Andrea Braga, 2011).

The social sense of urban form: Where do you come from? Where are you heading to?

Spatial pattern discontinuities endure the ways in which social categories occupy and regulate movement, mediating significant co presence and defining spatial governance. Integration, accessibility and connectivity hierarchical differences establish differences on movement potentials implied in the form and intensity co presence is organized according to each groups'

interaction strategies to members/non members. Foreigners elect and assign gathering places exploring more than one form of distance between themselves and those considered outsiders, through the routes they choose, through the spatial qualities that inform their locational choices.

Orthogonal grids distribute integration potential quite evenly. In such cases, slight differences on integration and connectivity potentials might be the clue to understand foreigners locational choices from which significant co presence patterns emerges. Movement potential and fluxes probability drive centrality processes shaped by the kind of movement they require and co presence they facilitate (HILLIER, 1999).

As for foreigner's movement and routes, we addressed the spatial strategies structuring gathering places network correlated to spatial configuration; their potential to connect to and command other network nodes and route segments is explanative of foreigners sociospatial locational strategies towards interfaces with themselves and to others. While in movement it is the route which identifies or classifies locals from strangers, in the way it provides straight paths to main collective attractors. Foreigners build strong links based on shared experiences along routes: tourists and immigrants alike, to the point they might be identified through them. They define borderlines to social appropriation of space, their reachable limits within the city spatial system.

If bounding is a self-organised spatial process related to groups strategic choices towards endogenous and exogenous forms of interface, spatial integration is prerogative to interact evenly with social diversity on daily practices, in co presence. According to an *Orchestra di Piazza Vittorio* member:

"Piazza Vittorio is changing, for better or worse, it is being transformed. Places aren't supposed to change on behalf of people who doesn't live there. Yet daily life imposes its own movement patterns, and changes on it are noticeable if movement is weak on market days; in other cases, changes are silent and people remain unaware of them, except those living nearby. And those who live here are Chinese tango dancers. What matters here is complexity, difficulties living together, being in co presence, these minor conflicts and integration gestures." (Piccolo, 2006, p.7).

Assuming that enclaves are space used as capital on gentrification or economical integration processes, than both, interethnic *Esquilino* and *Ameritown* in *Trastevere* are enclaves of different kinds: one remains a gated community, dwellers, even in transit, exert local control, transforming its social and spatial life in a way that jeopardize its cultural heritage. The other is open to global fluxes that transform sociospatial integration promoting interethnic conviviality not without conflicts. One enclave is a spatial compound, the other a strategic node in global networks which encompasses the whole metropolitan area and beyond. Both promote radical changes on neighborhoods landscapes.

Tourist's interaction with locals is selective and casual related to where they move about and might benefit from sociospatial segregation. Immigrant interaction with locals is essential to their socioeconomic integration, benefiting from spatial integration. On both cases their spatial strategies target to modulate interfaces to their own benefit. On both cases spatial governance is exerted, transforming places identities. Foreigner's practices, co presence and route choice become signifiers. Therefore, the questions:

Where do you come from? Where are you heading to?

Abstract. *Urban spaces transform into festival spaces when urban spaces are decorated with various ornaments and various events are held in urban spaces. In the case that audience over permissible amount crowd of festival spaces, it is theme to control audience for safety and to design good spaces to see at the same time. In Chichibu Night Festival in Chichibu city in Japan, which is one of the three biggest float festivals in Japan, there are three hundreds of thousands of audience in the last night of festival. Owners of the sites along the float route take two different ways as follows, to open outside spaces to put pay reviewing seats (reviewing spaces) or to close outside spaces by barricades (closed spaces). This paper aims to clarify characteristics of reviewing spaces and closed spaces in the case of Chichibu Night Festival in behalf of float festival in Japan. Findings are three points as follows. 1) Reviewing spaces are set to crossings, hill and Otabisyo (the place where the sacred palanquin is lodged during a festival) which are highlight areas of float festival, and are able to be typed three patterns by relationship between reviewing spaces and the ground, 2) The whole area where crossings, hill and Otabisyo are located changed closed space for safety because many audience crowd to, 3) In closed spaces, barricades are set up by plywoods and iron plates along boundary line of streets so audience can't enter the sites.*

Key Words: festival space, urban space, Chichibu Night Festival, reviewing spaces, closed spaces

Outline of this study

Urban spaces transform into festival spaces when urban spaces are decorated with various ornaments and various events are held in urban spaces. In the case that audience over permissible amount crowd of festival spaces, it is theme to control audience for safety and to design good spaces to see at the same time. In Chichibu Night Festival in Chichibu city in Japan, which is one of the three biggest float festivals in Japan, there are three hundreds of thousands of audience in the last night of festival. Because audience over permissible amount crowd around along the float route, owners of the sites along the float route take two different ways as follows, to open outside spaces to put pay reviewing seats (reviewing spaces) or to close outside spaces by barricades (closed spaces). This paper aims to clarify characteristics of reviewing spaces and closed spaces in the case of Chichibu Night Festival in behalf of float festival in Japan. I define reviewing spaces as the spaces which put pay reviewing seats and receive audience positively and closed spaces as the spaces which refuse audience by barricades, and both spaces have common features as follows, 1) these are festival spaces and 2) sites along the float route and 3) outside spaces.

Next, I talk about how to study. First, when I find reviewing spaces or closed spaces along the float route in Chichibu Night Festival in 3 Dec. 2012, I plot points of them in the map, photograph and film. Second, I type reviewing spaces about relationship between reviewing seats and ground. Third, I grasp areas which were closed during towing floats. Fourth I type closed spaces about materials of barricades.

The outline of Chichibu Night Festival

Chichibu Night Festival is held from 1 to 6 Dec. every year as annual festival of Chichibu Shrine. Main festival events in Chichibu Night Festival are 1) towing floats around town area, 2) playing Kabuki on the floats, 3) playing "Hikiodori" on the floats, and 4) towing floats from Chichibu Shrine to "Otabisyo" (the place where the sacred palanquin is lodged during a festival). Main places of Chichibu Night Festival are Chichibu Shrine, "Otabisyo" and Chuoh street which is main route of towing floats. Chuoh street 9-13 meters in width is main street. Modern buildings and historical buildings are mixed along Chuoh street. Towing floats event start from Chichibu Shrine, make a round of the Shrine, and arrive at "Otabisyo" by way of Chuoh street, Seijin street and Dango hill.

The characteristics of reviewing spaces

I plot points of reviewing spaces on the map (figure 1). There are 4 points near crossings (a, b, c in figure 1), 8 points near Dango hill and 1 point in Otabisyo. Every points are set near view points of towing floats.

Next, I analyze each reviewing spaces. Reviewing spaces are able to be typed three patterns by relationship between reviewing spaces and the ground (figure 1). First, there are 6 points called "ground level type" which are set reviewing seats on the same level of the ground. They are separated by red-and-white-striped curtains (A-3, A-5, A-6 in figure 1), blue vinyl seats (A-2 in figure 1), or color cones (A-1 in figure 1) between seats and streets. Sometimes chairs and benches are set. Second, there are 3 points called "stairs type" where reviewing seats are set like stairs (B-1, B-2, B-3 in figure 1). There are reviewing seats of stairs type in Otabisyo to enjoy seeing floats meeting together inside Otabisyo where people couldn't enter from 17:30 (B-3 in figure 1). Stairs type is good way in case of long depth of reviewing seats. Third, there are 4 points called "platform type" whose level is higher than the ground and flat. They are separated by red-and-white-striped curtains (C-4 in figure 1) or white vinyl seats (C-1, C-2, C-3 in figure 1) between seats and streets. Audience are easy to see floats because of high level.

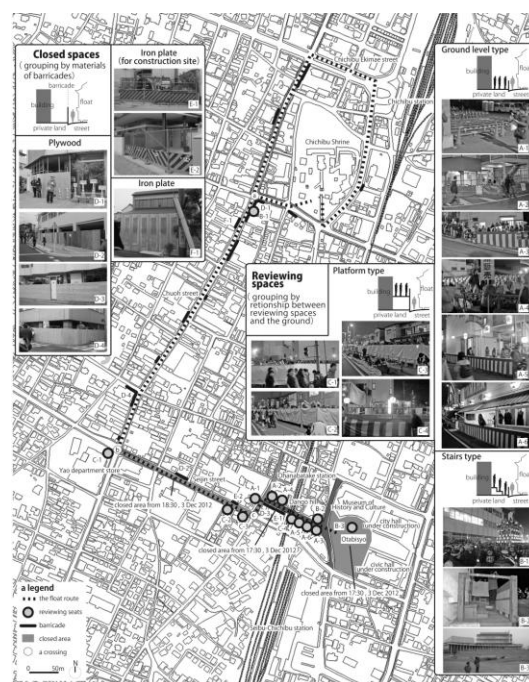

Figure 1. Reviewing spaces and closed spaces in Chichibu Night Festival

The characteristics of closed spaces

First, I grasp closed area while towing floats. There are three closed areas as follows, along Seijin street, along Dango hill and Otabisyo which are climax areas of towing floats (figure 1). Closed spaces are distributed everywhere along float route (figure 1). In all closed spaces, barricades are set up along boundary line of streets. The major materials of barricades are plywoods (D-1, D-2, D-3, D-4 in figure 1) and iron plates (E-1, E-2, F-1 in figure 1).

Conclusion

Findings are three points as follows. 1) Reviewing spaces are set to crossings, hill and Otabisyo which are highlight areas of float festival, and are able to be typed three patterns by relationship between reviewing spaces and the ground, 2) The areas of crossings, along Seijin street, along Dango hill and Otabisyo which are highlight areas of float festival are closed for safety because many audience crowd to, therefore areas itself are closed spaces, 3) In closed spaces, barricades are set up by plywoods and iron plates along boundary line of streets, so audience can't enter the sites.

Mi casa es tu casa: the creation of the new Rambla del Raval in the historic center of Barcelona, between urban renewal and touristic branding.

Alessandro Scarnato

Universitat Politècnica de Catalunya, carrer del Palau,
4, 1.1.08002, Barcelona, Spain. E-mail: zeroalfa@gmail.com

Abstract. *In the last twenty years Barcelona has become a top touristic destination. An important part in this achievement is due to the extensive effort in urban reshaping started in the 80's of the last century. The interventions in the historic center have had a key role in the regeneration and the promotion of the city on the global stage. The operations in the Old City (Ciutat Vella), led by famous architects like Bohigas and Busquets, were based on Aldo Rossi's theories on urban shapes, and followed an unusual dialogue between existing and new architecture. The creation of the whole new Rambla del Raval (1996-2001) throughout the demolition of almost 3000 houses in the historic tissue, has been the most consistent operation. The physical impact of the Rambla had been vast and deep: the transformations have gone way beyond the expected effects and one of the first consequences has been the creation of an ideal terrain vague where the increasing communities of non-European immigrants filled both the physical and social voids created by the interventions. The 'new' Old City of Barcelona entered in a process of gentrification, becoming a incredibly popular touristic destination, a result that was out of any plan when the renovation started. Newcomers (tourists, visitors and immigrants) have, quite obviously, adapted faster and better to the new morphology of the center and, differently from the locals, they appreciate the original historic features of old urban tissue. The paper, based on my PhD research, aims to describe how the urban process triggered by the Rambla del Raval has generated both physical and social transformations which had a mutual influence, far beyond the original intentions of planners, administrators and inhabitants.*

Key Words: Barcelona, historic centers, immigration, tourism, public space

Introduction

The historic center of Barcelona is now the administrative district of Ciutat Vella, the “old town”, which includes the large Raval sector, a once rural area that became part of the city when its walls were constructed in the fourteenth century. With the construction of the new grid extension of the Catalan capital designed by Cerdà in 1859, the old town entered into a rapid process of social and physical decline, with the Raval as a critical focus of poverty, insalubrity, prostitution and petty crime enhanced by its proximity to the seaport. The area, popularly known as the Barrio Chino, or Chinese Quarter, since the 1920s, was the most urgent problem facing the first elected Barcelona City Council (BCC) when it embarked on what was known as the “reconstruction of Barcelona” (Bohigas, 1985) in 1981. A detailed plan (Pla Especial de Reforma Interior, PERI) for the Raval was passed in 1985 as part of the Pla General Metropolità (Metropolitan Master Plan) of 1976. In the 1985 PERI, the architects Xavier Sust and Carles Díaz designed an articulated system of public spaces to be created in the dense urban fabric of the Raval, from the popular South sector (bombed during the 1936-1939 Spanish Civil War and subject to ongoing remodeling since the time of Cerdà) to the North sector, where a cultural hub of museums and university faculties was to be built, reusing and transforming the many abandoned religious buildings. In the late 1980s, Promoció de Ciutat Vella (Procivesa) was constituted, a company with joint capital (51% Barcelona City Council and 49% private investors) and the mission of managing the urban renovation of Ciutat Vella.

Shaping the urban matter

The 1985 PERI envisaged linking the interventions in the South and North sectors of the Raval by opening up a huge central space called the Pla Central del Raval (PCR) in the middle of the urban fabric. In its technical report, the project was described as a reevaluation of the entire district:

[By means of this] operation, five blocks will be demolished to create a large central space measuring 60x235 meters, similar to Rome's Piazza Navona. The existing buildings along the sides will be maintained while, at each end, a new construction will provide access to the space via a loggia. The treatment [of the new ends] must provide distinctive frontages on the new plaza, as they have to compensate for and balance the sides, where the [existing] irregular building is not of very high quality. (Procivesa, 1988).

The reference to Piazza Navona was used repeatedly, but the analogy was simply a geometrical reference, since the former Stadium of Domitian was the product of centuries of largely unplanned sedimentation, whereas this project was a planned and designed demolition and remodeling. The declared intention of respecting the existing urban fabric, local residents and popular atmosphere was stated as a priority in the operation, but it was no obstacle to the destruction of over 400 apartments in a significant change of scale from the surrounding neighborhood.

In the 1985 scheme (Figure 1), the short sides of the new plaza were supposed to comprise arcaded buildings incorporating the area's few noteworthy architectural features. These porches reflected the then common architectural aspiration to the Italian movement *La Tendenza* and were intended to give a visual order to the largely unplanned Raval environment.

In relation to other contemporary urban remodeling projects in Barcelona, the 1985 PERI suggested the continuation of operations previously carried out in the center. This continuity was, however, only apparent; unlike other projects such as Carme Fiol's Fossar de les Moreres, in this case the layout accorded no architectural value to the surrounding buildings. At the same time, its proportions ruled out any affinity with small interventions in the center, such as Plaça de la Mercè, a square created by demolishing a semi-abandoned residential block. Residents' associations pointed out that the overall design of the operation coincided with the location of blocks already affected by a process of expropriation started by previous, obsolete planning, as the architect Beth Galí noted: "[the Administration plans to] create this new space in the place where it is easiest [and] most convenient, without considering whether this is where it's really needed" (Espada, 1998). Frustrated plans from the 1950s and 1960s had in fact left their mark in legal and urban terms, making it difficult hypothetically to withdraw from processes of expropriation that were already under way, with all the foreseeable complications.

In 1987, two years after the Raval's new project had been approved, the details had still not been defined. Documents in municipal archives show a considerable number of sketches, notes and memos referring to subsequent specifications that were never implemented. Embryonic indications for the design of the floor plan revealed planners' uncertainty about the final morphology of the space, and no serious study of the elevations of new building was ever carried out.

The situation changed in the summer of 1990, when the University of Barcelona began negotiations with the City Council to move the humanities faculties to new facilities to be built in a large, empty urban space located in the former convent area of Raval North. The technical office of Procivesa welcomed the proposal and used it as an opportunity to rethink the whole 1985 PERI. In 1992, after signing the agreement with University, the Council decided to implement a preventive one-year suspension of expropriation and building permits on the future PCR site, pending a new project outsourced to the architect Jaume Artigues, which was completed in 1993. The new plan redistributed open spaces originally planned in Raval North, taking into account another operation promoted between 1991 and 1993 by the Generalitat

(Catalan regional government) in Raval South, substantially at odds with the 1985 PERI¹¹⁷. This new operation dismissed the arcaded square planned as an intermediate space between the future “Piazza Navona” and the construction site of Richard Meier’s MACBA. This tract of public space was brought within the limits of the Raval’s new plaza project, thereby reducing the number of buildings to be demolished in the area as a whole.

Figure 1. On the left, the map of the active expropriations in a plan from the 1985 PERI. On the right, a sketch of the first version of PCR, with the first layout of the Loggias. (from Arxiu Municipal del Districte de Ciutat Vella).

As regard the future space’s morphology, the 1985 PERI included the demolition of five street blocks, but the new version of the PCR did not include new constructions at the north and south ends, and would produce a much larger open space. The square it proposed did not look like a closed urban salon, since it opened onto the commercial streets of Sant Pau and Hospital. As regards the sides, the construction of the Riereta gardens to the west was postponed indefinitely, and, to the east, a new intervention was planned between the project site and the historic Carrer d’en Robador (Figure 2).

The technical argument used to justify the modification of the 1985 design was that the land where the north and south ends were to be built did not meet the requirements of the PERI, according to which any plot of land should be “intrinsically easy to address in constructive terms” (Artigues, 1993 and Artigues and Cabrera, private conversations in 2012). When municipal architects studied the executive aspects, various legal and technical complications emerged, particularly in relation to the management of land for which the 1985 project had not foreseen a unified treatment. A plan to rehabilitate the façades overlooking the plaza was added to the new project, which replaced the Italian influences of the first version with local architectural references. As a result of these changes, the area covered by the square (58x317 m) would be almost two acres.

¹¹⁷ The Generalitat was required to fit the BCC prescriptions only in few, basic elements. This fact has been, for some years, a generator of discrepancies in policies and operations between municipal and regional administration.

Figure 2. On the left, the 1993 proposal (Procivesa 1996). On the right, aerial view of the completed Rambla del Raval in 1999.

The amended plan received final approval in 1994, coinciding with European Union grants that would fund up to 85% of the operation. ERDF funding was obtained with a semantic trick because the project was presented as “environmental regeneration” in order to comply with grant requirements, designed to finance development based on ecological and sustainable criteria in accordance with the EU’s Green Paper. The semantic ploy was only apparent, however; the new plan really was a plan for environmental improvement. Besides increasing the amount of public space (enhanced by a double row of trees), the operation effectively reorganized all the technical services, introducing a pneumatic waste collection system and an efficient mechanism for draining and reusing rainwater to irrigate the trees. The project actually marked the end of the Raval’s long history of periodic flooding.

The architect Jaume Artigues materialized the new project jointly with the architect Pere Cabrera, of Procivesa. From a compositional viewpoint, it was a diligent Barcelona-style exercise, with one outstanding non-orthodox element: trees. The great mass of green (133 trees, including palms, planes and jacarandas) mitigated the colossal dimensions of the opening and constituted the main difference between the project for this plaza and the many places dures, the hard squares that had characterized the city in the 1980s, when local practice had tended to shun any visual elements that prevented the unitary perception of space. In the PCR, a hierarchy of grassy and paved areas culminated in a central section with a pedestrian corridor, designed for strolling and for setting up markets or similar activities. Throughout, lines of stones marking the outlines of the demolished blocks would punctuate the pavement. At the northern and southern ends, two large ellipses cut into the ground, highlighted by palm trees, mark the limits of the project without the volumetric solidity originally envisaged.

The new square emerged as a convincing architectural composition but caused considerable controversy as an urban operation. Criticism was initially leveled at real-estate issues; to give the project its final dimensions, the number of demolitions within the PCR area was extended (Figure 3), affecting some listed buildings such as the Modernista townhouse of Can Buxeres and the Sastre Marqués pharmacy designed by Puig i Cadafalch. The heritage status of these items had been previously downgraded to keep up an appearance of correctness. Though neither was a major monument, the chosen method (declassification) was hasty and led to protests in defense of architectural heritage. Many residents’ associations and individual citizens (including

famous names such as the writer Manuel Vázquez Montalbán and the dramatist Josep Maria Benet i Jornet) spoke out against the threat represented by the planned destruction of the Raval's historic fabric and a "Neighborhood Heritage Destruction List" was published¹¹⁸.

Figure 3. A picture of the first demolitions of PCR, in 1998.

Difficult as the proposed morphologic change of the district was, the process of expropriation was even more complex. Council administrators and local residents' associations had agreed on a model of compensation, with residents being required to demonstrate a minimum of five years' continued occupation and proof of legal occupation (utility bills were accepted) to be eligible. Those entitled were offered the choice of reallocation in the Raval or elsewhere in the city, or financial compensation. Although (as thorough documentation and interviews suggest) everyone who met the requirements and expressed the desire to stay in the area received satisfaction, conflict was inevitable.

Firstly, there was the attitude of the municipal employees, generally described as uncooperative. This was probably due to awareness that residents of other districts were trying to exploit the blurred legal situation of many buildings, the ownership of which was sometimes impossible to clarify; it was well known that many individuals, some highly conflictive, took up occupancy of apartments, pretending to be eligible for compensation.

There was also the unchecked economic trend. By late 1995 (coinciding with the start of demolition), there was a dramatic increase in real-estate prices, generating major friction between the Administration and residents about the expropriations, which had noticeably increased. Council planners did not want to postpone the construction once announced, since property values quickly outstripped the appraisals carried out in 1993, making them impracticable.

In operational terms, the granting of ERDF funds came as a boost, and in early 1999 the first project phase was complete. A huge celebration under the slogan "El Raval de la gent" (The Raval of the people) marked the opening, presented as a new lease of life for the district. The space was thus christened "Rambla del Raval", prompting local writer Quim Monzó to comment ironically on the contradiction inherent in a space that was designed as a plaza and came into being as an avenue to nowhere, with no clear purpose other than letting the sun in¹¹⁹

¹¹⁸ Vázquez Montalbán gave, in his novels of the 1980s and 1990s, a good description of the atmosphere of old Raval, perceiving the transformations going on. In 1999, Benet i Jornet described in the pièce "Olors" the drama of a Barcelona family who must leave the territory where have lived for generations. In 2000, activist Octavi Alexandre edited, on his own, an exhaustive list of historic buildings demolished during the renovation process of the center.

¹¹⁹ The writer Quim Monzó and the journalist Lluís Permanyer wrote several articles in the local newspaper *La Vanguardia*, pointing out that the name "Rambla" is supposed to be, in Catalan language, an avenue resulting by covering some former urban creek. The Rambla del Raval was, instead, a new cut in the urban fabric.

On September 16, 2000, the last building was demolished and the now empty space was inaugurated with a festive event. General enthusiasm momentarily took precedence over complaints about expropriation, demolition and social conflict. Newspaper chronicles described the end of “centuries of marginalization” of the Raval, whose residents could finally emerge from the neighborhood without being ashamed of their origin, and where ladies from the bourgeois Sarrià district could venture to visit the new Rambla without risk¹²⁰.

Figure 4. Municipal advertising in the local press, of the new Rambla del Raval. The slogan says: “Rambla del Raval, 1988 a project, 2001 a reality”.

Leaving aside the celebratory tone of press and officials, there were inevitably pros and cons to the Rambla del Raval operation. The pros included innovative design and private investment in remodeling buildings, which occurred surprisingly fast in comparison with other city-center sectors. Private spending totaled 890 million pesetas, whereas the Administration had spent 17 billion pesetas (85% from the ERDF), 8.3 billion of which went on reallocating 925 residents.

As regards the cons, real-estate prices had risen far more than expected: for a flat in a publicly rehabilitated building, the average price per square meter rose from 193,000 pesetas in 1995 to 230,000 pesetas in 2000. In the case of new warehouses or apartments rehabilitated by individuals, the prices tripled. For the first time, real-estate agencies specializing in the Raval appeared. This was positive in itself, but it led to a huge, unchecked rise in prices leading to speculation with private property and the unexpected effect of momentary stagnation of the market¹²¹. The apartments overlooking the new Rambla were sold for 400,000 pts/m², and the average rent skyrocketed from 15,000 to over 75,000 pts/month.

Turning to look at social problems, twelve months after the inauguration of what is now called Rambla del Raval, there was no perceptible sign of improvement. Drug dealing and use, petty crime and prostitution, poverty and insalubrity picked up where they had left off, and initial enthusiasm gave way to general disenchantment. The big question, repeatedly echoed by the local press, was whether such an enormous operation had actually been necessary.

¹²⁰ In almost every newspaper like *La Vanguardia*, *El Mundo* or *El País* between July and October 2000, there are daily chronicles of how the city of Barcelona was discovering the new space in the former Barrio Chino.

¹²¹ Such a contradiction in the economical ambit (the stagnation of the market coinciding with the rising of the prices) was only apparent: the administration had not considered, in original plan, that somebody out of Raval could have interest in invest in the area. The stagnation was, thus, the consequence of the enlargement of the potential range of buyers, since many owners were just waiting to see where was the new limit of the market.

Operation robador

Doubts and criticism gained intensity when work began on the project to remodel the adjacent area around Carrer d'en Robador in spring 2000. Unlike the new Rambla, the Robador plan could not even remotely be termed environmental regeneration; it was purely—and quite explicitly—an initiative on the part of Barcelona City Council to raise funds to avoid bank debt. This self-financing tactic, alien to Procivesa's mission, was based on a zero-profit logic, since improvement of the historic center would in itself generate substantial opportunities for business and prosperity (Brunet i Cid, 1996).

In the 1985 PERI, no significant intervention had been planned in the two blocks between Carrer d'en Robador and the new Rambla. Five years later, however, following the approval of the project's new layout, political voices were raised about the risks of such a large operation in terms of time and cost. Some parties called for a parallel operation to produce capital gains that would compensate for the dreaded rise of costs and secure a reserve of land that could, at least partially, be used for public infrastructures.

The solution seemed to lie in and around Carrer d'en Robador, one of Barcelona's most conflictive streets, famous for its round-the-clock prostitution that aggravated other problems like drugs, petty crime, STDs and lack of investment in private properties. A shock intervention here was therefore seen as an effective way to consolidate the success of the neighboring Rambla del Raval (Figure 5).

Figure 5. Layout of the Robador operation as presented in municipal advertising in local press in 2001.

At the end of 1994, Procivesa was commissioned to draft the plan. An initial layout envisaged the expropriation and demolition of 50 buildings, freeing up 12,706.48 m² of land, 2,700 as public gardens (initially referred to as the Jardins d'en Robador). Studies of the executive aspects started and, in 1995, the area was the subject of an international student architect competition at the UIA 96 Congress held in Barcelona (Procivesa, 1996).

To speed up proceedings, Procivesa decided to act as an independent agent in the open market in direct negotiations for buying properties, expediting the usual expropriation process. Meanwhile, the social climate heated up when the City Council confirmed that the buildings in the Robador area would be demolished. The brusque management of the expropriations, together with the popular belief that the promised gardens would be replaced by a private underground car park, increased local residents' opposition.

In 1997, the architecture practice Martorell-Bohigas-McKay (MBM) signed an agreement to develop a new detailed plan for the area. MBM's configuration included a new building for the UGT trade union headquarters, 10,000 m² of social housing and another 10,000 m² to be sold on the free market, plus 9,500 m² for trade or services, and a public underground car park. At this point, Mayor Joan Clos personally called for the addition of a 4-star hotel with at least 110

rooms—cutting 7,000 m² from other uses—to benefit from Barcelona’s booming tourist trade (Cabrera, personal conversation in 2012).

It was, then, unsurprising that by the late 1990s the Robador operation was exciting even greater expectations than the Rambla del Raval, exceeding purely financial concerns, as Deputy Mayor Xavier Casas wrote in a confidential note three days after the inauguration of the Rambla:

[To a] large extent, right or wrongly, general opinion about the results of the huge investment throughout Ciutat Vella will be strongly influenced by the success of the development of the Robador area and the Rambla del Raval. Since the latter is practically defined down to the last detail, we now have to decide on the profiles of the Robador area. The key importance of creating the [right] real-estate product is obvious.

Josep Martorell, one of MBM’s principals, was also apprehensive about the outcome of the operation, since his task involved basic planning, with no specific project and no supervision or overall coordination of the new blocks. Presented to the public in its final version on September 28, 2001, the new plan sparked controversy due to the volume of a 45-meter high hotel. This height exceeded the regulatory maximum and, since it was impossible to amend the Master Plan, the only way to keep within legal boundaries was to compensate for this height by removing the four top floors of the municipal tower block built in the 1960s at the heart of the Barri Gòtic. It was also decided to include in the operation the new Film Theater of Catalonia (eventually built just meters away) to attract cultural tourism.

Identity vs. Planning

The Robador operation turned out to be extremely complex, both administratively and practically. The presence of many undocumented immigrants in abandoned apartments and the speculative expectations of owners (at one point, harassment became a social emergency) fed tensions that had already been reactivated by the persistence of petty crime in the new Rambla.

It was at this point that the spectacular and completely unexpected increase in newcomers to the Raval emerged as a crucial element in the ongoing urban process. The demographic transformation had started slowly a decade previously but became clearly visible in the mid-1990s, when the newcomers, primarily Pakistani, filled in the gaps in municipal plans. It was no coincidence or simply a matter of low rents that the Pakistani community grew from 600 to 10,000 inhabitants in the same years and on the same site that the new Rambla was built. They filled the empty space with a visible identity, welcoming the opportunity of a livable public space well suited to a culture that was used to living much of its social life in public spaces¹²². The immigrants replaced the historic inhabitants with almost no conflict and saw the traditional urban fabric through new eyes, unaware of local prejudices and complaints about the infamous Barrio Chino. Moreover, the Pakistanis were interested in safeguarding their businesses and created vigilance against drug dealers and pickpockets. These extemporary initiatives were not enough to eliminate crime; many petty criminals benefited from municipal urban planning, since it provided fresh victims in the form of new residents or visitors from other districts. In addition, tourists began to be a considerable presence in the area, fascinated by the myth of the infamous Barrio Chino (however much less dangerous than many similar areas in London, Paris or Athens), and attracting even more pickpockets.

The increasing presence of foreigners, who had “inexplicably exceeded the locals in both trade and in attendance” (El País, 2001), became the main problem of the Rambla del Raval just a few years after its inauguration. The 1985 PERI was drafted with the ultimate aim of freeing the area from the marginal living conditions that had made the name “Barrio Chino” a synonym of urban poverty worldwide. Almost fifteen years later, the flamboyant new Rambla had erased

¹²² In 2002, a show called “Super Raval” featured a kind of Pakistani Superman who solved the district’s problems. In the same year, a movie, *En construcció* (directed by José Guerin), and a music compilation, “Barcelona Raval Sessions”, highlighted the far-reaching metamorphosis of the sector’s identity.

much of that wretched identity, leaving in its place a blurred image. Most long-time residents left the area, replaced by new communities, mostly from unfamiliar (for the most of Barcelonans) areas of the planet. At the same time, tourists became a regular presence, though showing far more interest in the now relatively safe bohemian atmosphere of places like Bar Marsella (whose absinthe was praised by Ernest Hemingway) than the contemporary urban and interior design promoted by Barcelona City Council (Delgado, 2005). In an attempt to create a landmark in the space, in 2003 a sculpture by Colombian artist Fernando Botero was installed in the southern stretch of the new Rambla. The presence of his gigantic bronze Gato (Cat) has been well received by residents and visitors, and has gone some way to moderate the frequent vandalism in nearby streets.

By 2005, the area was once again more dangerous than the rest of the center, though still not comparable to the dramatic situation thirty years previously. The residents' associations claimed that the Rambla had made things even worse, because its large empty space provided the young population (Erasmus students, squatters and local gangs) with a perfect public venue for socializing, with the attendant noise, consumption of alcohol and drugs, and fights. A more serious danger emerged in 2008, when petty crime and international Islamist terrorism unexpectedly joined forces; counterfeit copies of passports stolen from tourists on the Rambla del Raval by local pickpockets were found in the hands of Al-Qaida members in the Middle East¹²³.

The inauguration on February 12, 2012 of the Film Theater of Catalonia, designed by architect Josep Lluís Mateo, marked the end of the main interventions in the area, still [2014] dotted with street prostitution (officially banned since 2011) and latent social tension between the various groups of residents (Pakistanis, Africans, Europeans, Spaniards and Catalans). In this sense, the Rambla del Raval can be regarded as having failed to construct the new local identity envisioned by the plan's original mission.

At the same time, Artigues and Cabrera's project has reached its maturity as a work of public space design. Geographer Edward Soja could now [2014] hardly repeat the words he uttered in 2001, declaring that the Rambla was the worst thing he had seen during his visit to Barcelona (La Vanguardia, 2001).

Conclusions

More than ten years later, what was once a wide-open empty space is now a pleasant place that channels many surrounding pedestrian streets and is a reference point for neighborhood life. Thanks also to the successful activation of private investment in the buildings that line it, the Rambla has acquired a visual coherence, and many people who go there everyday do not realize that the space was created from scratch at the end of 2000. The large Pakistani community has played a significant role in this process, never expressing discomfort with the demolitions or the morphological distortion of the district, as many arrived in Barcelona when the main destruction was already past. In a curious historic tradeoff, the construction of the Rambla del Raval, originally designed as an urban improvement in response to a century-old demand on the part of a desperate district, has become the ideal scenario for all kinds of newcomers, playing the same role as a sandbox in computer security: it provides a safe environment for new arrivals, with relatively low conflict with the rest of the city, until the true nature of the process is clear. This probably explains why the area's important demographic change did not provoke the tensions and violence seen in other European cities at this time, including Barcelona's parallel operation in the eastern sector of Ciutat Vella, where a considerably less aggressive intervention produced

¹²³ The most remarkable case happened in the event of the 2011 Mumbai attacks, where the main commando used counterfeited passport reportedly stolen in Raval two years before.

major neighborhood confrontations between 1996 and 2004 (Calavita and Ferrer, 2000; Capel, 2005; Delgado, 2007).

Less clear is the effect of the Robador intervention, halfway between a clumsy attempt to mix different social realities (one of the most acclaimed ideas of the social democrat Council of the 1980s) and the clash of irreconcilable urban settings. This contrast is apparent every day around the tower block that is the 4-star Hotel Barceló, where middle-class tourists, street prostitutes and the Carrer Sant Rafael mosque share the same area with mutual suspicion, latent tension, minimum contact and no real interaction. In this sense, the fears expressed by opponents of the project, that hotel guests would use the Rambla as a drop-off point for their cabs without ever interacting with the environment, have been fully confirmed by daily experience.

However, the assertive morphological intervention of the Rambla del Raval has also somehow helped to dissolve the traditional barrier between the street and the inside of the city blocks. As Francesc Muñoz pointed out, many bars, clubs and restaurants recently to have opened in the area have big, transparent frontages and interiors that echo the compositional theme of the new outdoor design (Muñoz, 2008).

The real unplanned factor has been the tourist boom, not just as statistical data but as a phenomenon. In Barcelona City Council's political plans in the early 1980s, the creation of an appealing new image for the Raval was a clear objective. The role of the cultural hub in the northern sector and the "Piazza Navona" in the old Barrio Chino was to attract to this part of the old town Barcelonans who had previously never dared to pass the Liceu opera theater, the gateway to the "underworld" (Scarnato, 2013). The initial aspiration to Italian models of contemporary urbanism (particularly Aldo Rossi, Carlo Aymonino and Umberto Secchi) was supposed to represent a step forward at both urban and social level. The surprising success as a tourist destination of the Catalan capital after the 1992 Olympics was also fueled by amazing images of a remodeled Barcelona, where architects and planners were able to shape the city and, to some extent, its society. This, at least, was the mantra of many official messages around the change of millennium.

Neither the non-European newcomers nor today's large volume of tourists met these expectations. The Rambla del Raval is the stage of a social drama where, rather than following a common script, the actors try to inhabit the space according to needs, desires and possibilities only partially in keeping with Barcelona Council's original plans. For instance, the popular atmosphere of the sector lives on, as clothes hanging from the balconies (forbidden elsewhere) prove at any time of day. Pakistanis have adapted very well to the "Ravalestan" spirit, and both short- and mid-term visitors (between one and eight months) appreciate a moderately roguish environment. Moreover, tourism has a major impact on the current trend of apartment renovation, emerging as a trending habit on the part of owners and designers, once reluctant to see any technical or aesthetic value in the area's houses.

Behind the reevaluation of the physical characteristics of old Raval houses there is a trend with unpredictable and potentially much greater consequences for economic and social identity than the shock intervention of the new Rambla. The future of the area will depend largely on the stance adopted by Barcelona City Council on the effects for real estate of the area's touristic success.

The role of municipality in urban regeneration: the case of Lisbon's Eastern waterfront

Ana Nevado

DINÂMIA'CET-IUL, ISCTE-Lisbon University Institute.

E-mail: anacnevado@gmail.com

Abstract. *Urban regeneration as an integrated process is an essential component of the current and future public policies, which justifies its research. Post-industrial and declined areas, such as the Eastern waterfront of Lisbon, are complex and peculiar territories that require a critical look on urban regeneration and management. We analyse it aiming to understand the crucial changing role of the municipality in urban regeneration processes – through political, governance models and agents – as well as the main agents of change involved in strategic, collaborative planning. Within this scope, we consider the transformation of public policies, urban plans and governance models until now; the urban planning/management led by Lisbon's municipality, partnerships and public participation; the evolution of urban morphology of the case study and its relation with the city and the metropolitan area. Considering the contemporary context of scarcity of financial resources and the triggered challenges by globalisation, we intend to contribute to the debate on the evolution of spatial planning and management. We conclude that new ways of planning based on urban regeneration are emergent opportunities throughout the construction of networks of communication and cooperation among several agents of change - government, private sector and communities –, where Architects are elementary.*

Key Words: Urban regeneration, municipal planning/management, public participation, Lisbon, collaborative planning

Introduction

Urban regeneration is currently an essential component of public policies, which justifies its research (Portas 2003; Ferreira 2013). However, although urban regeneration is widely experienced, it is still a slightly understood phenomenon (Friecke 2007, p.2).

Despite there is not a standard/universal definition worldwide, in this particular context we define urban regeneration as integrated, inclusive, collaborative and strategic social and economic processes of (re)developing specific urban areas (MAOTDR 2007; 2013). Consequently, municipalities play a decisive role of planning, management and especially change, throughout the definition of strategies, political/governance models and instruments (Fidalgo 2012).

Many cities, especially industrial ones, were affected by the most severe industrial decline during the 20th century, leading to mass joblessness and subsequently an out movement of people (Friecke 2007, p.4). Post-industrial cities and urban areas suffered remarkable economic decline. De-industrialization brought about by reductions in demand for traditional products and intensifying competition from elsewhere has eliminated much of the industrial base, employment and social stability that existed in 1960's (Friecke 2007, p.4). The consequences for the cities – such as: polarization of demographic development between different regions (growth islands next to shrinking regions); demographic decline in cities with severe impacts on municipal housing (vacancy, deterioration), real estate market (decrease of property values), technical and social infrastructure (under-use) and retail development (lack of consumer traffic, slump in sales); ongoing suburbanization to the detriment of downtown development/population (Friecke 2007, p.4).

Urban development and urban regeneration are complex processes, which are influenced by many general conditions, such as the impacts of demographic and economic change (Friecke

2007, p.2). The current tendency of shrinking cities has been transforming urban planning and management in the last decades, focusing on and highlighting urban regeneration operations.

The Eastern waterfront of Lisbon is peculiar since it is a complex, post-industrial and declined area (Custódio and Folgado 1999) in the city, requiring a critical look on its urban planning and management, according to strategic, integrated and collaborative planning (Alves 2001; Ribeiro 2012).

We analyse it aiming to understand the crucial changing role of the municipality in urban regeneration processes, through political, governance models as well as the main agents of change involved in strategic, collaborative planning. Within this scope, we consider: (i) the transformation of public policies, urban plans and governance models until now; (ii) the urban planning/management led by Lisbon's municipality, partnerships and public participation; (iii) the evolution of urban morphology of the case study and its relation with the city and the metropolitan area.

Aware of the implied difficulties in urban regeneration and the new challenges imposed on Urban development policy, we intend to contribute to the debate on the evolution of spatial planning and management through the analysis of conceptualizing, monitoring and management practices of urban regeneration operations in the territory as well as the main agents of change involved, focusing on Lisbon's municipality.

Considering the contemporary context of scarcity of resources, funds and the triggered challenges by globalization (Ferreira 2005), we conclude that new ways of planning are emergent and an opportunity (Tyler, et al. 2013) throughout the construction of networks of communication and cooperation among several social actors - government, private sector and community (Alves 2001) – where Architects are elementary.

Urban regeneration and (re)development: strategies, instruments and agents of change

In this section, we focus on a brief enlightenment of the main strategies and instruments led by municipalities on urban regeneration to cope with urban decline and the most important agents of change that are involved.

It is important to be aware of the fact of the meaning of urban regeneration has widened since the early 1990s, when it was associated mainly with economic and infrastructural development (Davies 2002, p.9). However, it is now an umbrella term understood as the promotion of the social, economic and environmental well-being of an area (Davies 2002, p.9). The wide-ranging and integrated visions and actions of urban regeneration lead to the resolution of urban problems, seeking to improve economic, social and environmental conditions of specific urban areas that have been changed (Roberts and Sykes, 2000:17 cited in Friessecke (2007:6). Therefore, urban regeneration means improving the physical, economic and social well-being of current cities (Friessecke 2007, p.1). Over the past years it has played an important role due to the changing demographic (i.e., shrinking populations, ageing, diversification of lifestyles and migration) and economic (i.e., globalization, the deregulation of markets, rise in unemployment) conditions (Friessecke 2007, p.1). Those complex processes lead to a strong pressure for urban change due to vacant land and building, obsolete or under-used infrastructure and social segregation (Friessecke 2007, p.1), such as gentrification.

Urban regeneration programs are locally and regionally developed, inducing the participation of several formally independent organizations and individuals (Figueira 2007).

In council-manager governments, the council is more generally expected to arrive at some sort of consensus of views (Davies 2002). The task of the council may even be interpreted as finding the best means to ends which are assumed to be agreed upon (Davies 2002).

In Portugal, as it happens worldwide and especially in the U.S.A. and U.K., Central Government is becoming more influential in the local policy arena (Davies 2002). The model of 'governing without government' (Rhodes cited in Davies 2002, p.1), depending on the interaction of public and private sector actors in (informal) networks in order to generate

economic growth, is being departed from the influence and control by central states (Davies 2002, p.1), especially since 2008 (Crisis). Although partnerships are a distinctive mode of governance (Davies 2002, p.1), having been developed in the 1990s, they are losing strength. Hence, individuals and organizations must collaborate to achieve goals (Davies 2002, p.5). Empowerment (or collaborative synergy) is an important issue for theories of networking and regime governance is a highly specific form of collaborative politics and a specialized form of networking (Davies 2002, p.5-8).

Whereas urban planning and urban development in Europe have been heavily development-orientated with the focus on extending infrastructure and designating new residential areas, globalization, demographic and economic change leads to substantial changes in urban development policy (Friecke 2007, p.2). Urban growth has been replaced by stagnation and shrinkage processes at many places in Europe in the last decades (Friecke 2007, p.2). This process of change rises to new challenges and tasks for the federal governments, states and municipalities and results in a new planning range and readjusted urban support instruments coping with shrinkage (Friecke 2007, p.2), such as urban regeneration.

Facing deep transformations, cities are undergoing structural changes (Friecke 2007, p.6) as its governance models through multi-scale networks (Davies 2002). Urban regeneration is a multidisciplinary approach that requires a well coordinated set of strategies and options (Fidalgo 2012, p.8). Currently, it is one of the main goals of urban policies of central and local entities at national and international scales. In the contemporary context of change, urban policies and especially integrated processes highlight the need to rethink the relation between citizens, State and territory in terms of models and solutions of governance, considering, however, the individualities of each municipality.

Nevertheless, it is important to highlight that urban regeneration is beyond *urban renewal* (which is an essentially physical change process), *urban development* (general mission) and *urban revitalization* (which has no precise method or approach and is fundamentally about social-economic transformation) (Lang 2005, p.8 cited in Friecke 2007, p.6). It should be based upon a detailed analysis of the condition of an urban area and seek to ensure consensus through the fullest possible participation and cooperation of all stakeholders with a legitimate interest in the regeneration of the area (Roberts and Sykes 2000, p.18 cited in Friecke 2007, p.6), which can be achieved through partnerships (Friecke 2007, p.6).

In general, and according to Friecke (2007), the priority objectives of urban regeneration can be specified in the following categories: (i)improving housing and living conditions of the residents of older districts; (ii) strengthening and supporting the vitality and economic functions of such districts; (iii) renewing and preserving their building stock as well as their urban physical and social structure.

There is a variety of themes and topics involved in urban regeneration, and the multiplicity of interrelated outputs (Friecke 2007, p.6). Nevertheless, any urban regeneration strategy needs to be adapted to each circumstance and place within which it operates (Friecke 2007, p.6).

We follow the definition of urban regeneration including the principle of ensuring sustainable development in all areas of public and private policy as a “comprehensive and integrated vision and action which leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental condition of an area that has been subject to change” (Roberts and Sykes 2000, p.17 cited in Stouten 2010, p.28).

As in many other European countries, the role of local authorities became marginalized as central government began to encourage planning in partnership with private investors (Stouten 2010, p.27). The relation between State, city and citizen grew apart (Ferreira 2005). Cities became agents of state, dependent on putting national public policies into practice and legitimizing forms of land management prescribed by the state (Stouten 2010, p.27).

Today local governments are taking the initiative, within their own constitutional limits, to launch programs of urban regeneration in a climate governed by a pan-European concern to

adopt a uniform cooperative policy (Couch, Fraser and Percy 2003; Drewe, Klein and Hulsbergen 2008 cited in Stouten 2010, p.28). The strategy adopted for urban regeneration involves a continuous process of refurbishment and modernization of the urban fabric rather than short-term fixes (Stouten 2010, p.28). This strategy combined physical, economic and social restructuring, re-engineering and reinvention of the city-region (Ravetz 2000, p.274 cited in Stouten 2010, p.28), such as: (i) Physical restructuring, continuous and city-wide, to achieve strategic environmental targets; (ii) Diversification of employment and the economy to counter risks generated by globalization; (iii) Social empowerment through community action and the third sector economy; (iv) Urban and environmental planning for the city-region ('a sustainable development framework').

Being aware of spatial relationships underlie territorial politics at all levels (such as neighbourhood, city, regional, state and global) (Stouten 2010, p.28), we consider that urban development is influenced by the relationships between spatial and social processes that have been developed during the last decades (Stouten 2010, p.28).

Main strategies and instruments: Partnerships

It is consensual in Europe (e.g.: Netherlands and UK) on the importance of an appropriate model for a more compact, mixed-use urban form towards the creation of sustainable cities (Raco 2007 cited in Stouten 2010, p.52). A compact city gives priority to urban regeneration, the revitalization of the city centre, restrictions on planned developments in rural areas, high density, mixed functions, public transport and the concentration of urban development at public transport interchanges and the concentration of urban development at public transport interchanges and, to encourage sustainable development, reduction in the use of motor vehicles and pollution and minimizing the loss of rural areas (Stouten 2010, p.52-53).

The financial situation in many cities is concerning, so that municipalities ascertain losses of revenues to finance urban (re)development, local public transportation improvement and the construction and maintenance of roads, schools, hospitals, cultural and sports facilities (Friecke 2007, p.1). Therefore, partnerships between public and private sector may be a reasonable instrument for urban (re)development and urban revitalization.

The range of partnership activities is divided between 'policy' and 'implementation' types (Davies 2002, p.9). Collaboration tend to be structured in the production of 'policy' partnerships responsible for establishing goals and making funding bids, and 'implementation' partnerships responsible for project delivery (Davies 2002, p.10). These types of partnerships exhibit different collaborative dynamics (Davies 2002, p.10). However, the endogenous dynamic to regeneration dynamics is weak (Davies 2002, p.10).

According to Elkin (cited in Davies 2002, p.15), current partnership structures would have to be redesigned to enable local innovation and autonomous action. For instance, in the U.S.A., while local governments are 'creatures of the state', they enjoy practical autonomy (Stone 1998, p.2 cited in Davies 2002, p.15). According to Rhodes (cited in Davies 2002, p.15), autonomy is a condition of networking, trust and diplomacy, although it is not an evident feature of local regeneration politics in Britain. However, local collaborative dynamics remain weak across a wide range of local governance activities in Britain (Davies 2002, p.16), due to the fact of: not only regeneration partnerships but also local politics in general, are characterized by hierarchies which are becoming stronger (Davies 2002, p.16); it is easier to build and sustain where the influence of central government is weakest (Davies 2002, p.16); where new participatory mechanisms have been established as part of the drive to re-build local democracy and they have succeeded in mobilizing sections of a given community, they have not given local citizens more control over local politics (Davies 2002, p.16). Participatory strategies have not resulted in bottom-up networks, because they are constrained by hierarchical tendencies and also because non-state actors do not have sufficient leverage, once involved, to make a difference (Davies 2002, p.16).

According to Figueira (2007, p.33), urban planning and management depends on public participation through the coordination between several agents and multidisciplinary groups: (i) representatives of political and administrative power, mediators and policy makers related to the choices within spatial planning; (ii) Professionals (technicians, experts and investigators) with relevant and specific academic skills/competencies, provided with technical know-how about interventions on territory; (iii) Economical agents and potential investors, i.e. stakeholders, on rentable outcomes of urban operations (e.g.: private sector); (iv) civil society, i.e., common citizens and/or final receivers of the taken urban options, decisions and interventions on the territory that they occupy (e.g.: local communities and residents).

According to DGOTDU (2002), public participation in urban planning is a right of citizens, through the participation on the elaboration, alteration, revision, execution and evaluation of territorial management tools, as well as formulating suggestions and requesting for clarification through those processes and participating on the final phase of public discussion before the approval of urban plans (Figueira 2007, p.12-13). In general, public participation is related to the capacity of involving local population and communities on social development of their territories (Sanoff 2000, p.1 cited in Figueira 2007, p.13). «[Public Participation] reduces the feeling of anonymity and communicates to the user a greater degree of concern on the part of the management of administration. [With] it, residents are actively involved in the development process; there will be a better maintained physical environment, greater public spirit, more use satisfaction and significant financial changes.» (Becker 1997 cited in Figueira 2007, p.13).

The strengthening of public participation on urban planning and management reflects on the reinforcement of democratization of/on that process, which reflects a wider and more consequent involvement of society (Figueira 2007, p.57). Thus, other methodological approaches are needed, in order to guarantee participated, inclusive and integrated development processes, such as decentralization of power of decision (Figueira 2007, p.57). We consider that this approach may be advantageous in urban regeneration through the reinforcement of local administration entities (i.e.: Municipalities and especially Parishes) (Figueira 2007, p.57), interactive processes (Figueira 2007, p.11) throughout regular debriefing sessions with local communities and also incentives for people to present problems and proposals to improve the city and its specific urban areas, that would be discussed and later reflected on urban plans (e.g.: Municipal Master Plans), as a way of (re)developing a (symbolic) sense of belonging and identity with the territory (Figueira 2007, p.57). This type of effective, strategic and collaborative participation on urban planning and management is performed through cooperation (such as partnerships and delegation of power) and also controlled by citizens, since its contribution determines the final decisions (Figueira 2007, p.12).

The role of municipality in urban regeneration processes: the case of Lisbon's Eastern waterfront area

Considering that the city is the stage of democracy and public participation is structurally fundamental on urban regeneration processes, in order to achieve social cohesion and to (re)develop a sense of trust and identity between communities on specific urban areas, we analyze the case of Lisbon's Eastern waterfront. That complex, post-industrial and declined area (Custódio and Folgado 1999) in the city requires a critical look on its urban management. due to its urban evolution and importance of industrial and port activities, is currently a declined area. Therefore, the role of municipality has in urban regeneration processes is essential, through the implementation of public policies, such as *Política de Cidades - POLIS XXI* (MAOTDR 2007; 2013) and also urban plans. This scenario reveals an innovative management philosophy on urban and spatial planning and management in large cities (Ferrão 1994; 2013), considering not only the administrative boundaries that are defined on the Municipal Master Plan (CML 2012) but also promoting social, physical and economic connections with the surrounding region, i.e., its metropolitan area (AML 2001).

We consider the case study area along the Eastern waterfront area of Lisbon (Portugal), specifically between *Santa Apolónia* and *Parque das Nações*. The consequent urban mutations and evolution of the city, since its rural genesis (XVth century), the important industrial and infrastructural overlap (during the XIXth century) and the aftermost declining process from 1960s, built complex and heterogeneous urban landscapes until today (Custódio and Folgado, 1999; Nevado 2013). The implementation of pollutant industries, large scale infrastructures (e.g.: railways and port activities), disqualifed neighbourhoods and the consequent process of deindustrialization and the transfer of industry to other metropolitan areas around Tagus river (e.g.: *Margem Sul*) since 1950, in parallel with globalization and urban sprawl on Lisbon's metropolitan area, promoted the lost of importance of Eastern waterfront area transforming it as peripheral in the city in the last decades (Nevado 2013).

However, nowadays that territory represents opportunities through urban regeneration, by reconnecting Tagus River to the city, articulating port areas with consolidated/obsolete urban tissues and reconnecting it to central areas of the city through the reinforcement of accessibilities.

Local authority in Municipalities is implemented through several entities - such as Town Halls, its Representatives (i.e.: Presidents), Municipal Assemblies and Parishes - that determine the use and form of occupation and development of cities (Figueira 2007, p.33). In the last decade, communities have been required to participate on urban regeneration, through meetings in local Parishes and Town Councils (Figueira 2007), forming partnerships (e.g.: *Parcerias para a Regeneração Urbana* (Fidalgo 2012; CML 2012), among other strategies with benefits for redeveloping urban declined areas (Tyler, et al. 2000).

But although public-private partnerships for urban regeneration are a useful tool, they are still not sufficient for solving the current problems. Thus, it is needed a wider political strategy that involve not only public investment programs but also private ones, in order to stimulate the renting market, reviewing the estate tax system and also the legislation on urban rehabilitation (Fidalgo 2012, p.vii). As we can identify on PDML – the current Municipal Master Plan of Lisbon (CML 2012) -, the Municipal Council of Lisbon has been redirecting efforts towards urban regeneration of the Eastern waterfront area of the city, for instance, by transforming and updating the legal framework of renting regime. Despite some lack of articulation between urban policies and the *Administration of the Port of Lisbon*, urban plans and especially Municipal Master Plans focus on urban regeneration and rehabilitation (e.g.: PDML) (CML 2012). The role of municipality is, therefore, essential in urban regeneration of Lisbon's Eastern waterfront and to articulate it with other areas on the city, improving employment and attracting people and investment.

Considering the transformation of public urban policies (Ribeiro 2012), urban plans and governance models until now, The urban planning/management strategies and instruments (e.g.: urban policies, urban plans such as Municipal Master Plans and strategic urban plans) led by Lisbon's municipality, partnerships and public participation as well as the evolution of urban morphology of the case study and its relation with the city and the metropolitan area, we conclude that the changing role of the municipality in urban regeneration processes is crucial, especially in the current context of scarcity of financial funds (Bourdin 2011).

Conclusions

Considering the contemporary context of scarcity of resources, funds and the triggered challenges by globalisation, we conclude that new ways of planning are emergent and an opportunity throughout the construction of networks of communication and cooperation among several social actors - government, private sector and community – where Architects are elementary. We intended to contribute to the debate on the evolution of spatial planning and management, focusing on the role of Lisbon's municipality on urban regeneration on the Eastern waterfront area of the city.

In this study we analyzed the role of municipality in urban regeneration operations on the Eastern waterfront of Lisbon, focusing on the main agents of change and the need of alternative methodological approaches. The chosen case study stands out for its ability to generate new visions and practices of urban regeneration through municipal action, public discussion and participation, under a flexible coordination and combining different types of agents. Considering the long-term of urban regeneration projects, its institutional and financial complexity, it is necessary a wide political and social support for strategic and prospective (re)development proposals. Besides physical transformations, urban regeneration must provide social consensus, closer relations between citizens, developers and local authorities in order to be successful. Therefore, interactive collaboration among communities and institutional entities is needed in several phases of development, implementation and review of legal mechanisms of municipal urban planning and management, to (re)create and reinforce a sense of identity with the occupied territory. Public participation plays a fundamental role during the several phases of the process, in order to supply integrated approaches.

We emphasized on the relation of local government structures in processes of urban regeneration, to contribute for the economic growth and development of communities. There is still needed greater flexibility and transparency of political processes - especially on urban planning, management and regeneration -, as well as wider coordination between Administration entities and scales (e.g.: Central VS Local), decentralization and a monitored execution through innovative processes of governance and partnership, including local and regional actors (Ferreira 2005).

Once that redevelopment strategies and operations are not only a local but global phenomenon, the involved entities and communities need to be coordinated at different scales (e.g.: city-region). Hence, the role of the municipality on urban regeneration is crucial to update IGT, diagnose problems and advantages, test and implement urban regeneration proposals and alternative scenarios for the waterfront of Lisbon, articulating it with the city, its metropolitan area, at a national scale and in global networks and flows, as an international port city.

This study also reveals that part of the handicaps of municipal/local planning of the last decades can be surpassed through different methodological approaches (such as partnerships, public participation and debate, and urban plans/instruments of territorial management) with advantageous outcomes. The current legal framework highlights Municipal Master Plans as synthesis of the strategy of local (re)development (Rodrigues 2005, p.136). Therefore, the conception, management, execution and monitoring of the urban plans must embrace public participation of local communities (Rodrigues 2005, p.136), in order to achieve social cohesion, more inclusive approaches on urban (re)development - especially on urban regeneration -, and forming consensus about competitive development of global cities (Figueira 2007, p.1) besides connecting communities to the contemporary city (Lawless and Pearson 2012).

In general and in spite of urban decline, waterfronts of post-industrial and port cities are emergent central areas, fulfilled with opportunities through urban regeneration and strategic (re)development. Considering the scale of contemporary metropolitan city, the situation of obsolescence, diversity and rigorous field of the *Administration of the Port of Lisbon* on the riverfront, the Eastern area of Lisbon is a relevant case within the scope of urban regeneration. Although EXPO '98 global event and operation of urban regeneration had redirected critical looks on this area, the current situation of urban decline along the river triggers challenges of contemporary urban/spatial planning and management. However, that area is emerging in the current context of scarcity of financial resources, through the implementation of strategic models of municipal urban restructuring and (re)creation of central areas and identity.

The re-appropriation of industrial sites in the urban form of the post-Communist city

Iulia Statica

Department of Architecture and Design, La Sapienza University of Rome, Piazza Jose de San Martin, n. 1, 00197, Rome, Italy. E-mail: iulia.statica@yahoo.com, iulia.statica@uniroma1.it

Abstract. *The paper purposes to analyse the phenomenon of the re-appropriation of post-communist post-industrial urban sites in the city of Bucharest. The study aims to develop an interpretation of the various conditions, from the technological to the ideological, that has contributed or could contribute to determining the nature of the re-appropriation in terms of both urban memory and functional re-use. Initially, the study will examine specific urban, industrial sites built between the late 19th and early 20th centuries, as function of the industrialization of the Romanian economy, seen in their development in the urban topography. From the middle of the 20th century, these spaces were included in the communist project of growing Romanian industry. Examining the extent of the embodiment of the communist ideologies in projecting a new urban form, the second part of the paper will investigate which was the role of ideology in the process of appropriation and re-appropriation of these industrial sites. In today's Bucharest a big part of these spaces, lots of them already part of the industrial archaeological patrimony, constitute huge un-used areas blocking the fluidity of the urban tissue. The paper thus asks, can the contemporary re-appropriation of these sites result in an authentic rehabilitation of the urban tissue, generating forms of political praxes that negotiate the various historical layers or appropriation and re-appropriation which would mediate different understanding of urban memory and different experiences?*

Key Words: Industrial sites, ideology, re-appropriation, urban memory, re-use

Introduction

The perpetual changes in the urban spatiality, the projects overlapping or successive in time, are themes shaping the city's specificity. Especially when certain events occur having a deep impact at the social, economic or political level, the city reacts through changes manifested at a physical level (the fabric of the city) and more important, in the way the new changes are appropriated by the inhabitants (Stanilov, 2007). The almost 25 years from the 1989 Revolution allowed, more or less, the new forces to manifest and to re-shape the post-Communist, city following new principles. As Dingsdale noticed, 'urban form has been often described in social theory as a passive element of our social existence, a mirror reflecting past and present socio-economic conditions, or a "text" serving as a basis for their interpretation' (Dingsdale, 1999: 65).

The paper brings the hypothesis that industrial areas constituted significant spaces not only for the economical context, but also they manifested themselves as urban and mental landscapes both in Communism and post-Communism, representing one of the main themes which shaped the urban topography. Furthermore, the socio-economic changes engendered by the fall of the Communism can be clearly observed in the industrial areas. Their decline is probably the most prominent site of the transition period manifested into the urban tissue (Kiss, 2007: p.147). It proposes, therefore, that Bucharest can function as an exemplary context, through which the issue of the re-appropriation of the post-Communist industrial spaces can be considered. After the fall of the Ceausescu regime, the decline of the industry determined the emergence of disaffected or ruined spaces into the urban topography, acting now as huge spaces of numerous layers of history. The industrial architecture of Bucharest was of major importance during the Communist era, but it, currently, exists as large patches of dead or underutilized urban tissue.

The paper's purpose is to examine the evolution of spatial patterns of the industrial landscape both in the Communist and post-Communist city's topography.

The first part of the study will draw the evolution of industrial spaces in Bucharest showing the way they influenced the form of the actual city. Their evolution before and during Communism will be explored. Having as well an ideological purpose – where the propaganda was omnipresent – they led to deep changes in the urban tissue not only by their own presence, but also by determining the emergence of new housing districts for the people who migrated to the city. The second part will try to give an understanding of these spaces in the Communist context, connecting them with notions belonging to the common imaginary and *habitus*. The 'industry' and the 'factory' represented semantic elements during Communism being the realm where ideology fully unfolded attributing to these spaces a moral connotation (Chelcea, 2008: p.98). The works of Henri Lefebvre and of some texts belonging to the Critical Theory will serve as framework for approaching concepts such as *urban memory* and *ideology*, seen in their relation to the theme of industry. The final part of the work will concentrate on the contemporary re-appropriation of these industrial sites by the urban tissue. The impact of political and socio-economic transformation can be clearly observed in the industrial areas of the post-Communist city. One of the many areas of the city of Bucharest will serve as example for investigating the way these spaces have adapted or not to the new capitalist post-Communist context.

Before 1989, along with social housing and buildings of representation, the most important theme in terms both of architecture/urban planning and social manifestation was the industry. Even if in the Western countries, the end of the industrial era began much earlier, in the Eastern part of Europe it ended only after the fall of Communism. The economic changes were strictly connected with the political regimes and they involved radical transformations at the level of urban form and social perception of the city. These changes can be easily observed in the industrial areas of many post-socialist cities (Kiss, 2007). Their contemporary understanding is not only connected with the economic importance but it also has cultural dimensions. According to the era in which they existed, they also determined various controversies related to the cultural place they occupy in the industry of the city. Since their emergence, in the second half of the 19th century, the industrial spaces would represent a source of exploitation for the pre-war socialists, whilst the nationalists will consider them a symbolic contamination with craftsmen coming from other countries (Chelcea, 2008: p. 9). During Communism, these spaces will be seen by the Party as a source of progress and as the main spaces where the propaganda was disclosed. For the workers and the inhabitants around them, the ideology's rituals present in the factories became a tiresome manifestation of the regime because of the official visits and of the excessive visibility in media and in the 50s literature (Chelcea, 2008: p.9). Today, again, a new semantic is assigned to these spaces, mainly informed by their economic potential. Apart from the nostalgic image which still persists in the collective memory, they are now 'haunted' by the 'urban developers' who consider them as real business opportunities due to their central location.

The two layers of the city – the Communist and the post-Communist one – coexist as framework for the new development being superimposed over the old urban fabric (Stanilov, 8). In most cases, this overlapping of such different patterns also reflected the chaotic manner in which the city developed. The factors that have contributed to the greatest extent to this development have been generated by the new players and by the misapplication of some developmental schemes taken from the West and applied without caring too much about adjusting them according to the context, anyway precarious. The block type structure, unitary, of the state, for more than 50 years, was after 1990, fragmented and dissipated in various directions because of the political, social and economic interests (Stanilov, 8).

The theme of industry in Bucharest before 1989

Before 1880, Bucharest's economy was characterized by small handcraft industries. There were few exceptions, as the Assan's Mill (1853), the Metallurgical Factory Le Maitre (1864), The Brick Factory Max Tonolla (1865) or the Ceramic and Basalt Factory (1865). The rhythm of industrial growth increased significantly also due to the establishment of the National Bank of Romania in 1880, with the support of the liberal party which had the power at the time. At the beginning of the 20th century, the number of factories started to grow, such that in the 30s there were 332 factories. The accelerated growth of industrial development in Bucharest was due to various factors including its status as capital, acquired after 1859¹²⁴. Hosting the state institutions influenced both the growth of the industry and the intense urbanization of the city (Chelcea, 2008: 101). The administrative factor was very important as well, especially after 1918 when, after doubling the territory and the population, the administration increased even more¹²⁵. As a result, Bucharest was, until the beginning of the 20th century, rather a consumer city than one of production (Madgearu, 1999: 132), meaning that it represented a large market for selling different products. Another factor which determined the industrialization was the expansion of Romanian Railways (Caile Ferate Romane), which created new opportunities for the city's industry through a rapid and cheap transport of the merchandise. New train stations were built – Filaret Train Station (1869), Gara de Nord (1872) and Obor (1904) – which constituted the core of Bucharest's industrial areas (Chelcea, 2008: 104). The most important industrial areas of the city began to take shape. Their location was determined mostly by the railroads and other transportation networks. Therefore, in the first decades of the 20th century, six main industrial areas could be identified in the urban landscape, all of them having as common point a strong connection with the transportation routes. Later, during Communism, a period obsessed with production (it was a production society, not a consumer society!), the rhythm of the economy, especially industry, grew much faster than in the West. In short time, the industry became completely nationalized: the main companies were the first to go, by a decree of 11 June 1948, and the others followed (Boia, 2001: 119). Soon after that, other three industrial areas emerged, due mainly to the growth in the number of the population and to the city's expansion, but also to Communism which tried to exploit the whole industrial potential of the city. This era presented a huge opportunity for outlining a new spatial structure of industrial activities due to the new regime which reshaped drastically the socio-economic system. However, the former industrial zones within the city did not change much – most of the factories being rebuilt or reused on their existing sites. Being at that time under the USSR's influence¹²⁶ and seen as well as an element of propaganda, the evolution of the industry was made through the modernization of the nationalized factories and presented in a very triumphalist way in the journals of that time. During this period, the economy of Bucharest was no longer guided by the market, but by the "plan", as a general principle of organization (Chelcea, 2008:112). Ceausescu emphasized the industry's development rate without taking into account the real economic indicators. These were completed by an absolute economic control. On the short term, this economic system had a positive impact on the social plan: a large amount of working places was created, the urbanization of the villages and a relative wellbeing. On a long term, it turned out to be a bankrupt policy which determined the industrial specialization of whole regions, without offering alternatives. At a large scale, the Communists would invest only

¹²⁴ Bucharest became the capital of the two Romanian provinces (Moldavia and Wallachia) after their unification on 24 January 1859.

¹²⁵ For instance, in 1930, 15% of all the public servants from Romania were living and working in Bucharest (Golopenita, 2002: 350).

¹²⁶ The USSR's influence manifested in Romania from 1947, after the abdication of King Michael I, until 1965, with the beginning of Ceausescu's government. Where Gheorghiu-Dej (the Communist leader after 1947) had hewed to a Stalinist line while the Soviet Union was in a reformist period, Ceausescu initially appeared to be a reformist.

in three fields: the heavy industry, infrastructure and projects with a propagandistic character (the Danube-Bucharest Canal and the transformation of Bucharest into one of the ports to the Danube, the Civic Centre and the People's Palace, and the transformation of the villages through systematization into agro-industrial cities). The period between 60s and 70s is the period of quantitative expansion but qualitative reduction, both at the dwelling level and industrial activities. Bucharest becomes the target for great investments in the industrial field (the development of IMGB factories, or Republica, old Malaxa). It is also the time when large housing districts will be built due to the increasing job offer in the capital and also to the migration of the people from the countryside to the city. Districts as Berceni, Titan-Balta-Alba, Drumul Taberei, Colentina, Rahova, Ferentari or Crangasi are consequences of these changes. These new buildings were very modest in terms of space for living for each inhabitant, but also in terms of the quality of the services – reason for which they were nicknamed 'matchboxes'. The forced industrialization also absorbed an important part of the rural population and it sent them into the towns where they were never fully integrated (Boia, 111). In communist Romania, urban planning was centralized, technocratic and subordinated to national economic objectives. It proceeded within the institutional and ideological framework of a single-party system (Hirt, 2005: 222). The building of a new world was announced: 'entire areas of the towns were flattened, without sparing historical buildings or even tiny segments of the traditional urban landscape' (Boia, 2001: 136). The district of tower blocks and the factory¹²⁷ became the great symbol of Communist modernization. The idea of the transformation of the towns as the ideal solution was embedded in the human consciousness by the very aggressive propaganda showing the magnificence of the newly-built areas. This attitude is also part of a rhetoric of the 'active new' characteristic for the Communist discourse. The new tendency implies 'the erasure of the traces left by the capitalist society founded on exploitation and its replacement with a new built environment that would rest under the sign of satisfying the material and spiritual needs of the working class' (Zahariade, 2011: 34). As a consequence, the country has to become an immense building site.

Industry as embodiment of ideology

Assuming the theoretical system of Henri Lefebvre, the production of space can be framed into three categories: representations of space, spaces of representations and spatial practices. Transferred to the Communist and post-Communist cities, all these three elements contribute to the shaping of spaces, to their re-semantization and assignment of different understandings. The representations of space which imply ideology and power can be best put into relation with the industrial spaces and their role in the Communist system. After Communism, and implicitly, after the end of the industrial era, these spaces continued of course to be part of the urban tissue, engendering the production of other types of spaces: "the shift from one mode to another must entail the production of a new space" (Lefebvre, 1991: p.46). The industrial spaces have been – from spaces of representation of the ideology during Communism to the most encountered actual condition of waste land – subject of nostalgias and fuel for visions of reconstruction or preservation, without trying though to integrate them into the lived present (Boyer, 1996: p.1). The Communist industrialization – a 'transformist' phenomenon of general mobilization itself – needs people in order to occupy the work force. For this, the first step is constituted by the industrial and general massification of the education. According to the instructions of the 12th Congress of PCR (The Romanian Communist Party), 90% of the students graduating secondary school will be enrolled in industrial and agro-industrial high schools (Cernat, 2008: 235).

¹²⁷ On the cover of one of the touristic guides for Bucharest, issued in 1962, the factory was illustrated as one of the main urban elements which contributed to the identity of the city (*Ghidul Bucurestiului*, Dan Berindei, 1962).

To which extent the Communist appropriation of the industrial sites resulted in the normalization of ideology, and by extension of the integration of ideology into the daily praxis? Here, we may speak of a ritualization of space, referring to the types of industrial and political praxes that evolved in the industrial Communist period. In the terms of the Critical Theory, ideology, 'spatialized or otherwise, is not just *false consciousness*' (Goonewardena, 2005: 51) as Althusser noted, but at some point, it comes to represent also the reality, in one way or another, besides reflecting it wrongly. In other words, during Communism, the ideology became part of human daily praxes, and proposed, instead of a naturally-appropriated tradition, a new tradition. 'However, while admitting that they [ideologies] do not correspond to reality, i.e. that they constitute an illusion, we admit that they do make allusion to reality, and that they need only be 'interpreted' to discover the reality of the world behind their imaginary representation of that world (ideology=*illusion/allusion*)' (Althusser, 1971: 162)

Ideology, said Althusser, is necessary in every society which needs its people to be formed and transformed in order to respond to the offered conditions of existence (Althusser, 1990: 235; Goonewardena, 2005: 53). 'Ideology, [...] springs from a situation in which social life has become too complex to be grasped as a whole by everyday consciousness. There is thus the need for an imaginary model of it, which will bear something of the oversimplifying relation to social reality that a map does to an actual terrain. Society, in the terminology of the eighteenth century, has become 'sublime': it is an object which cannot be represented. 'For the people as a whole to get their bearings within it, it is essential to construct a myth which will translate theoretical knowledge into more graphic, immediate terms' (Eagleton, 1991: 151).

Space as a general concept has always been seen in relation to 'notions of human utopia, whether social, political, or economic' (Buck-Morss, 1994). Space is not a passive surface, a *tabula rasa*, but, as like other commodities in the words of Walter Benjamin, is itself actively produced on the one side, and it has in its turn influences on the humans that are part of it. After Communism, along with the industrial buildings it was not just ideology that was dissolute, but also a 'particular collective and individual identity, a social order that sustained life both physically [...] through the communities and solidarity that emerged within them' (Pusca, 241). Any kind of shift from a political or economic system to another 'must entail the production of a new space' (Lefebvre, 46). The space is produced by the conditions and context it takes place in. The human factor is also a significant component of the image and appropriation of a certain territory, and as Richard Sennett assumes (*Flesh and Stones*, 1994), the body and the built environment have always had a very strong symbiosis along the history, the morphology of the ancient cities being closely related to the human body – as, for instance, the need for a centrality. The traditional city gathered its inhabitants around central squares where some symbolical institutions such as a church or parliaments were being housed. The modern city, and especially the Communist city, removes these landmarks from the urban topography or simply shifts the core of the community towards places of production such as industrial sites, around which all the human activity is now concentrated. The city of Bucharest had a fragmented structure, being organized in heterogeneous *mahalale* (slums), which constituted themselves around centers, usually marked by the church. They represented the basic cell which determined the structure of the entire city. After the instauration of Communism, these cells not only physically dissolved by being incorporated into the new proposed urban tissue, habitat of a 'new man', but especially in symbolic terms, by destroying their centers and by replacing them with spaces of production. The Communist strategy will attempt the urban and social unification and rationalization and the main themes of the city will be the industry and the social housing. They will constitute a priority for the socialist project and over the old fragmented structure of the city a new one will be overlapped, unifying tissue which will modify not only the morphology of the urban topography, but also a certain natural appropriation of the space already learned and in a way ritualized in the human consciousness. The many years of Communist regime, also determined a re-semanticization of the city and of its landmarks. The new conditions ideologically imposed transformed the initially pseudo-reality into a lived reality which started to be appropriated by the inhabitants.

The industrial sites after the 1989

The end of Communism brought about radical changes in the context within which urban planning operates, such as: the development of a multi-party political system; a more stratified society; the re-introduction of private property rights to land and various structures; the end of the Communist economic; the highly decreased role of public institutions and the emergence of a great variety of actors, mostly from the private sector (Nedovic-Budic, 2001). Covering up a significant part of the city – the industrial spaces are now lying in ruin or underutilized, forming large patches of dead tissue in the urban fabric. After 1990, many of Bucharest's factories have deeply changed their purpose. The effects of deindustrialization could be both seen in terms of urban metamorphosis and as social problem (Chelcea, 2008: p.243).

The new changes, both in terms of law and economy, were the main conditions that weakened the urban planning as well. The development of the private sector, the re-consideration of the lands and real estate market (Hirt, 2005: 224), but also the chaotic way of reacting in a democratic regime whose practice was missing, would represent elements which would diminish significantly the management of a controlled and rational urban growth and change. After the huge housing districts inherited from the former regime, the most significant weight in Bucharest's urban landscape will refer, after 1990, to the industrial sites. They are still seen to embody, maybe the strongest, the heredity of the previous regime. Relevant for the urban topography and imaginary in their various stages these spaces should now be re-appropriated into a new paradigm, of the post-industrial post-Communist city and should deal the various layers of understandings and legacies of their past in order to re-integrate them into the actual urban tissue and memory.

To outline the way the industrial sites in the city of Bucharest have evolved, I will use as example the case of one of the industrial areas in Bucharest – Stefan Cel Mare – Obor – Pantelimon. I will consider three industrial spaces belonging to this area in order to emphasize the way in which the urban tissue has developed in the last 25 years. The chosen industrial spaces also represent images of the way in which these fragments of the city have been reutilized in the post-Communist post-industrial city.

Urban renewal as tabula rasa

Many of the historical industrial spaces have been demolished during Communism because they didn't satisfy anymore the standards for production, and few of them were demolished after 2000. The gesture of *tabula rasa* seemed to be the only choice to exploit the land underneath the Dambovită Mill, one of the oldest mills in Bucharest. The site in question included actually two mills, one of them, Olmazu Mill, whose building date is not very sure, but which appears on the 1911 city plans; the other, very close to it, the Commercial Mill, was built in the 20s. After the nationalization, in 1948, the two mills merged into Intreprinderea de Panificație Dambovită which was demolished in 2005-2006 (Chelcea, 2008: p.199). In 2005-2006, it was demolished with the purpose of using the land for the construction of a new housing project. It was the first time when the public opinion reacted at this kind of urban gesture. Becoming part of the collective memory of the area and of the city, it was presented as well as urban and epic landmark in some Romanian literature books.

Ruin

Situated in the same area and built in 1853, the Assan's Mill was the first steam mill in Romania, using the most sophisticated equipment for that time and marking the beginning of the industrial era in the country (Chelcea, 2008: p. 203). After the nationalization law in June 1948, it became the state's property and it continued to function under various purposes. The Mill marked the surrounding urban space, also seen in the toponymy of the streets named after the mill and its activity: Assan's Boat, Fainari (related to the flour), Silozului (Silo's Street),

Irimicului (Middling's Street), and others. After 1990, becoming also part of the national patrimony, the mill is now a private property left in ruin in the middle of Communist housing blocks. The Assan's property covered initially an area of more than 5,41 acres, but because of the blocks built before 1990, the area of the industrial complex was diminished to 4,7 acres. Currently, all the buildings of the complex are in an advanced stage of degradation. Expected to disappear by itself, in order to make room for new investments in the terrain situated in a central area, the complex was subject to various mysterious fires and free of any type of security which led to vandalism.

Partial use and conversion proposal

The Malaxa Factories were began being built during the 1930s. Today, the industrial complex covers an area of 91,16 acres. The most important and valuable part of the complex was edified between 1930-1943, by the famous Romanian architect, Horia Creanga, in the modernist style. They are now part of the national architectural and industrial patrimony. After the instauration of Communism, the factories remained for a while under the control of their owner, due to the financial support given to the Socialist Party. Taken by the state after the immigration to the US of Nicolae Malaxa, at the end of 1940, they were renamed in the 60s the *23 August Factories*. "The Communists transformed them into a symbol of the fight of the workers against the capitalist 'exploiters'". Becoming a 'city within a city', this complex of factories had more than 17 000 employees during the 70s and maybe some more in the 80s (Chelcea, 2008: p. 219). Today, part of them is still in use at a very low capacity, with less than 400 employees, some of the buildings are rented as office spaces, but as a whole they still represent an underutilized space. In 2003, a study and a project for the conversion of the whole industrial area was made. 'Located in the Eastern area of Bucharest, in the proximity of the lake chain, an area deemed as an extraordinary natural patrimony to be developed for entertainment and leisure and, offering access to the Danube (the Oltenita fluvial port) by means of the railway terminal (Bucharest Titan stop), the FAUR industrial site could be integrated into the town reconversion by taking-up specific industrial activities, such as storage and services, ensuring the direct and fast connection to all great European industrial towns located in the area influenced by the Danube, reaching all the way to the North Sea, and this confers it the opportunity to be included in the European configuration of the global development strategies'(Radulescu, 2010: p.41)¹²⁸.

Conclusion

As a general conclusion, the paper suggests that the radical change produced after 1989, on various levels, has manifested deeply its influence in the urban landscape and especially in the former industrial areas.

One of the main center of production during the 20th century, 'affected' by a late de-industrialization because of the political regime, Bucharest finds itself today in the situation of searching for new purposes for the disaffected industrial spaces. The mismanagement of these spaces is caused also on the one hand by the fact that these spaces, nationalized by the law of June 1948, were claimed by the inheritors of the former owners, who will try in many cases to exploit the lands having a significant value. On the other hand, even if, in theory most of them belong to the national patrimony and their protection is mandatory, the new owners found each time a way to destroy indirectly the monument.

In terms of the urban and social semantics, their presence along all these decades in the core of the city has contributed to establish a relationship between them and the inhabitants, and normalize the symbolical value of these various fragments in the urban tissue. Therefore, the

¹²⁸ Radulescu, I., 2010: 'Faur – Uzinele Malaxa – Un sit industrial de interes european' 'Faur – Malaxa Factories – An Industrial Site of European Interest' in *Seria Arhitectura*, 2, n. 2, vol. 1

recovery of these spaces, having not only a symbolical value, but also an architectural and economic one, should imply not only their re-insertion in the functional urban tissue, but also the preservation of their character as landmarks of memory.

Urban mobility - Urban mutations. Means transport and morphological changes in the city of Belém

Fabiano Andrade, Inah Silveira

Faculdade de Arquitetura e Urbanismo – UFPA, Secretaria de Planejamento –
Governo do Estado do Pará. E-mail: fabiano@ufpa.br, inahsilveira@yahoo.com.

Abstract. *Urban mobility is among the important agents that contribute to morphological changes of city, new routes are executed and/or enlarged, large spaces transformed and resized, new technologies and techniques tried and updated, at the end they all linked the intensity of demand of the population. The history of Belém do Pará contains direct influences of design mode of Portuguese overseas cities from the early 17th century: strategic location on the margin of a river, articulation with the place where it was implanted and regular trace of the urban grid (Teixeira, 2012). In the 19th century, a large lowland area was grounded, expanding the regular layout with new avenues, and with the significant increase of the urban population, two trams companies settled also contributed with expansion of roads. However with the start of construction (1883) and the inauguration of Estrada de Ferro de Bragança-EFB (1908), and with the lifting of the “Primeira Légua Patrimonial” (1883-1886), authored by Manoel Odorico of Nina Ribeiro, that Belém began major changes in their morphology. The study shows the transformations arising from urban mobility in two spaces of great importance for the town of Belém: the “Complexo Viário de São Braz” and the “Complexo Viário do Entroncamento”.*

Key Words: urban mobility, history, morphology, means of transport, mutations

Means of transport of passengers and cargo and mutations in Belém (1870-2014).

Carts, Trains, Tramways, Garapeiras, Zeppelins, Buses and Cars (1870-1948).

The city of Belém in Pará State, Brazil, belongs to the territory of Eastern Amazonia and is part of a plain, where the levels of land relative to sea vary with dimensions of -4, 00 m to 18.50 m, still possessing water basins and a very high water table level, which makes it liable for flooding caused by atmospheric precipitations especially when these coincide with high tides, flash floods that occur mainly in the areas of lower quotas.

Due to inner city watershed structure and geographical location, the means of river transport represented by vessels of all sizes and quiet has always been present in Belém that is bathed by a bay and a big river, as part of its territory, several islands located nearby. Its ports receive vessels from all the States of the Amazon region, especially the municipalities of the State of Pará in the northern region, including those located on the Marajó Island.

Small boats both rowing (mounts and barges) as sailing (canoes), can still be seen today navigating streams that penetrate into the urban area, as is the case of the Igarapé do Tucunduba, which bisects the Campus in the neighborhood of Guamá. Those boats and those of other sizes and models, but can be seen in the daily life of the edge of the city, sliding the Guamá River and the Bay of Guajara, or anchored in ports and docks like “Ver-o-Peso”, nodal point and visual landmark in Belém.

Unfortunately the means of river transport intraurbano in the city of Belém no longer happen, symbolically, from the first decade of the 19th century, with the beginning of the embankment on the large flooded the Piry, and then gradually through rectification and channeling of arms of rivers, streams and creeks. In generally, speaking, these interventions have contributed and still contribute to the emergence of new avenues, when fully grounded, or if kept and ground, in this case allowing the use of its banks for the construction of pedestrian routes or car routes.

The first company of Tramways circulating in Belém do Pará was the "Estrada de Ferro Paraense", owned by the North American James B. Bond, hired in September 1, 1869. In 1874, this company no longer belonged to the American businessman, who had sold to Manoel Bueno & Cia in 1870, which transferred rights acquired for a company of joint-stock company. However, everything indicates that in the same year, Manuel Bueno created the "Company of Bonds Para" to manage cars pulled by pairs of donkeys, rail gauge 0, 75 m, but that did not begin to operate immediately in the city (Província do Pará, 1874).

Third owner of the so called "Urban Railroad Company Para", the Corporation developed its activities with 3 locomotives, 12 passenger cars and freight cars 8, that constituted the undercarriage for both main lines and for a branch, all gauge 1, 435 m, your responsibility.

The first line which connected downtown, taking as a starting point the Government Palace Square, until the "Arraial de Nazareth", an extension of 3.413 Miles, has contributed significantly to the development of the nascent Neighborhood of Nazareth, still considered the outskirts of the city.

The second line which connected the "Largo de Nazareth" through Independence Square and ending at one of the limits of "Primeira Léguas Patrimonial", represented by the "Boulevard da Câmara", contributed to the definition of two other important neighborhoods, São Braz and Marco.

In 1873 the two lines transported a total of 265,343 passengers. Even with this performance, reviews the use of steam trams multiplied. Questions about quantity of locomotives to be insufficient, the unraveling of the curves, the wrong choice of the gauge onto the tracks, the use of tracks already used, and especially why animals have not been used as traction (Província do Pará, 1874).

The incorporation of the trams of animal traction, the "Company of Bonds Para" on urban practice didn't happen before 1874. The important thing was that taking advantage of the layout of existing roads in the three neighborhoods already solidified of Belém, "Cidade Velha, Comercial and Campina", installed their lines and expanded its services. In 1894, the "Urban Railroad Company Para" assumed all lines of trams and continued to contribute to the expansion of the urban area of Belém until 1905, when it was sold to the company of English origin "The Stop Electric Railway and Lighting Company". Two years later, in 1907, began circulating the trams moved to electricity, the so-called Tramways, the responsibility of that company. And in 1908, the streetcars of animal traction have been disabled.

For 40 years, the electric trams of The Pará Electric Railway and Lighting Company "contributed significantly to the expansion of the city of Belém, taking his pace declined, by war economy, during the period of the Second World War. No longer circulate in the year 1947, paradoxically for reasons of economy of electric power to the city, but it wasn't just that the reason. Others, such as the increase in population, urban sprawl, the emergence of new neighborhoods with consequent increase in the number of routes, and the competition from bus.

The increase of the quantity of these vehicles in the last ten years has been quite significant, went from 87 existing units in 1938 for 300 units in 1947 (Tobias, 2004). These vehicles, in addition to the conventional historical models had, including those manufactured with wooden and/or assembled in the city itself, as the "Garapeiras", that worked from the early decades of the 20th century until the Zeppelins, which circulated from 1948, they all not depended on Rails or electric energy to work and were places not served by Tramways, also contributing to the extinction of that collective means of transport, which was already considered obsolete for mass human displacement (Mendes, 1998).

Buses, Trucks, Trailers, Cars, Motorcycles and Bicycles (1948-2014).

The legacy of roads left to the town of Belém since the plan/survey of Nina Ribeiro in 1883-1886, implemented and become reality for many municipal administrations, was such, that from the year 1948 until 1988, the year of the country's new Constitution, which allowed the creation of the Transport Company of the City of Belém - CTBel, urban transport in existing routes

coexisted in Belém. The road network was enough at that moment for the displacement of the inhabitants of the town, in the various modes of transportation, really happening facts significant that caused the high population density index and the increase in the number of vehicles on roads, such as the invasions of areas of lower level quotas, "baixadas", where traditionally inhabited people of lower purchasing power the large number of housing estates, consolidated in the late 1990, intrusions on the periphery, urban sprawl and the verticalization that starts in the early 50 in central District.

However, in the Decade of 1990, historically inherited road network began to reach the limit of its capacity, in relation to the amount of existing vehicles, especially in relation to the number of automobiles expanded in recent years, and recently by the large number of bicycles.

With the little wide road network, in the next decade, from 2000, the presence of the automobile in Belém and in other municipalities of the metropolitan region has intensified, as demonstrated by the sheer numbers recorded in the period from 2001 to 2012, from 142,032 to 300,275 cars, meaning an increase of 111.14%. Nevertheless, in figures, the participation of motorcycles is even more expressive, 8.1% in 2001 to 27.7% in 2012, in relation to the total number of vehicles in the Metropolitan Region of Belém (Rodrigues, 2013).

Urban mobility and mutations in two important areas of the City

Complexo Viário de São Braz

This space has been studied recently in its evolution as a public square, in the research project presented the UFPA, under the title of "Analysis of changes in urban space and buildings of the city of Belém do Pará: architectural and urbanistic truths of every project executed", and which gave rise to the work plan entitled "Mutations of the former of Largo da Independência in Belém do Pará 19th century, later named Largo de São Braz to the current area occupied by squares of the Trabalhadore, Leitura, Floriano Peixoto and the Municipal Market, Set the IAPI, bus station and other buildings in it deployed" (Fig. 01). The designation used here aims to establish terminological binding with another space then parsed, and already known by the technicians as the "Complexo Viário do Entroncamento".

The "Complexo Viário de São Braz" began to form even in the 19th century, when from the Largo de Nazareth, in the year 1862, there emerged a new road in continuing the Road of Nazareth. This new Road, named as "Independence", with approximately 1,200 metres ahead and in a straight line, opened in a large space, which in 1861 was Independence Square, then called the Largo de São Braz and later Praça Floriano Peixoto (Cruz, 1945; Muniz, 1904).

Already with the name of Largo de São Braz, the large space was represented graphically in its fullness, in the city of Belém plant prepared by polytechnic engineer Manoel Odorico of Nina Ribeiro, to the City Council of Belém from 1883 to 1886. The Largo, possessing an initial area around 28 ha (Fig. 02), with 700 m long and 400 m wide, that already showed that representation had been deployed, inside, some urban facilities, High Reservoir (water tower) and the first Railway Station building of Estrada de Ferro de Bragança. Were also shown and identified the rails of the means of transport, using the space of Largo as a path. Historical photos show a few dwellings located in their extremes, indicating the feasibility of housing and the possibility of offsets to the inhabitants to the location and to the city center (Muniz, 1904).

One of the tracks depicted in the map belonged to second line of steam trams of "Urban Railroad Company Para", described above, and which connected the Largo de Nazareth until the Boulevard in front of the camera. The other representation of tracks belonged to the line of trams pulled by animals of the "Company of Bonds Para", which connected the Largo from Nazareth to the cemetery of Santa Isabel. The third representation of tracks belonged to the Branch of the railroad, which connected the São Braz Station to the Central Station of Belém, located in the public garden (Andrade, 2010).

Complexo Viário do Entroncamento

The name of “Entroncamento” for this space exists since the first decade of the 20th century, but still in the 19th century, there were forecasting and rail project would ensure its future existence. The space analysis is an important Point Nodal¹²⁹ the city, which lies at the intersection of Almirante Barroso Avenue, main entrance and exit of the city, with the Augusto Montenegro Avenue. These two avenues have hosted or were created from the tracks of the

¹²⁹ There is no doubt that the “Complexo Viário do Entroncamento” is a “nodal point” in accordance with the concept of the five elements created by Kevin Lynch to analyze the image of the city: “(...) strategic places of a city through which the observer can enter, are the intensive outbreaks for which or from which he travelled. Can be basically joints, places of interruption of transportation, a cross or a convergence of routes, times of passage of one structure to another. Or they can be mere concentrations begin to be important because it is the condensation of some use or any physical characteristic, such as a meeting point in a corner or a closed square.” Lynch, Kevin. *A Imagem da Cidade*.

main Line of the Estrada de Ferro de Bragança (EFB) and the tracks of the “Ramal de Pinheiro”, respectively.

‘The terrain “Entroncamento” remained preserved in its original triangular shape (Fig.03) until around 1965, when they were disabled the services of the railway, and from there came to be occupied by wooden buildings in precarious conditions of hygiene and safety, mostly for commercial purposes to foodstuff, until the early 1980, when it was vacated entirely for the construction of a memorial even without changing the original shape.

The lack of road alternatives for entrance and exit of Belém and access to neighborhoods of their expansion area, caused in the following years the density of traffic in that area. Road interventions performed at the “Entroncamento” from the years of 1990, for traffic congestion solution, which charted in the following limits of saturation, not brought significant improvements to urban mobility. In order to reverse this situation, in January 2014, was deployed in space the "Complexo Viário do Entroncamento" (Fig. 04), consisting of three high, small tunnels and pathways snippets extension.

Final Considerations

It is clear by the historical summary of modes of transportation in the city of Belém, that the mutations occurred in the flooded areas, rivers and creeks watershed located in the urban area, can not be used for the emergence of new waterways, which could contribute in the present day with a more ecological and sustainable utilization for the benefit of the quality of life of the

inhabitants of the city. These mutations of the urban space, since the first major land runs, had as a priority the creation of new roads to link important points of the city and improve the traffic of people and animals. The 19th century was in its early decades, but the morphological change of that area and other areas throughout the city, following the same principle, are sources of trouble until nowadays. The intense rainfall regime of the Amazon region and the coincidences with the high tide brings back the same situation for these areas every year.

The two spaces chosen for analysis of morphological changes induced by urban mobility, different from the historical situation of the areas flooded and backfilled, are situated in pockets along structural pathways that have higher level dimensions of the city, reaching 18 feet above sea level, which makes them immediately, valued differentiated areas for execution of architectural projects, urban and infrastructure of urban mobility.

The influence of the means of transport on the morphology of these spaces is found in its genesis, as was the case of the “Complexo Viário de São Braz”, that had one of their main routes defined by the internal steam tram line in 1870, and another route their initial coverage area defined by rails of “Ramal da Estrada de Ferro de Bragança” that went from São Braz to the center of the city in 1887. In the case of the “Complexo Viário do Entroncamento”, its original triangular shape and area were defined by the rails of the main line of “Estrada de Ferro de Bragança” and the rails of the “Ramal do Entroncamento – Vila de Pinheiro” in 1906, and by meeting the guidelines required for rail projects at the time, in the specific case to the stroke of the train lines, establishing large cornering, with greater than 100 m, for the execution of the maneuvers come true with the total security required.

Tracing Urban Catalysts in ‘Noorderkwartier’ Area

Arnoud de Waaijer

Julianalaan 134, 2628 BL Delft, The Netherlands.

E-Mail: D.A.deWaaijer@tudelft.nl.

Abstract. *After WWII the ‘Noorderkwartier’ Area, North of Amsterdam functioned as overflow for the city. Spatial policies in the Netherlands at that time aimed at reducing urban pressure on the ‘Randstad’. (Cammen, 2013) Costly policies of redistribution of urban development towards the peripheries were developed. (Healy, 2007) As a result a dispersed territory arose often linked to car mobility. Nowadays the policies are severely scaled down (Healy, 2007) and the area is confronted with possible downfall in population, employment, facilities and building production. To counter this for the area currently policies on Transit Oriented Development are under construction. (Provincie, 2010). Central in the concept of TOD is clustering spatial developments around nodes of public transport and thus re-establishing proximity. (Priemus, 2007) The research methodology applied to develop these policies mostly does not involve societal and spatial dynamics of these formation processes (Aken, 2004) This research aims to identify the key factors in urban change in relation to proximity to transit for understanding the processes involved to develop possible grip on the matter. By mapping the area historically since the commencement of transit and through spatial analyses the critical changes are identified for TOD. The processes underlying these critical changes will be studied and placed in their context.*

Key Words: urban morphology, transit oriented development, urban transformation processes, mapping, Amsterdam Metropolitan Area

Tracing Urban Catalysts in ‘Noorderkwartier’ Area

After WWII the ‘Noorderkwartier’ Area, North of Amsterdam functioned as overflow for the city. Spatial policies in the Netherlands at that time were aimed at reducing urban pressure on the ‘Randstad’. (Cammen, 2013) Costly policies of redistribution of urban development towards the peripheries were developed. (Healy, 2007) As a result post WWII a dispersed territory arose often linked to car mobility. Nowadays the policies are severely scaled down (Healy, 2007) In the most recent note on spatial policies (Ministerie van Infrastructuur en Ruimte, 2011), the role of the state is decreased to investments in infrastructure. By indicating where it is willing to invest in the infrastructures needed it aims to navigate spatial developments. Should the market be willing to participate in such spatial development the public will invest in those previously appointed projects. Currently the area of Noorderkwartier is confronted with a possible downfall in population, employment, facilities and building production. While simultaneously the means for intervention are limited to infrastructure investments and the provision of knowledge (Healy, 2007). At the provincial level currently a development is ongoing in the program ‘Densification around nodes of public transport’ which is part of the current main spatial policy (Structuurvisie Noord-Holland 2040, Kwaliteit door veelzijdigheid) (Provincie Noord-Holland, 2010). The policy has with its focus on transit locations and the aim of densification the characteristics of *Transit Oriented Development / TOD*. In the concept of *TOD* clustering spatial developments around nodes of public transport and thus re-establishing proximity is key. (Priemus, 2007) A normative standard for the influence of transit is the radius of 800 meters which coincides 10 minutes of walking which coincides with the distance generally considered to be acceptable as walking distance. The distance of 800 meter around a railway station is what defined as the railway station location.

In the early phase of this policy the methodology of the ‘Node-Place Model’ of Bertolini is used. The method is theoretical in character and gives on the bases of numerical input on spatial

development en transport provision predictions on to be expected developments in the railway location, The model does not take spatial and structural aspects into account (Waijjer, D.A. de, 2014). At a later stage, with the policy related publication ‘Maak Plaats!’ the reality of the locations would have been confronted with the Node-Place model. The predicting model is replaced by the ‘evolved’ ‘Vlinder-model’ (Leidraad Maak Plaats, 2013).

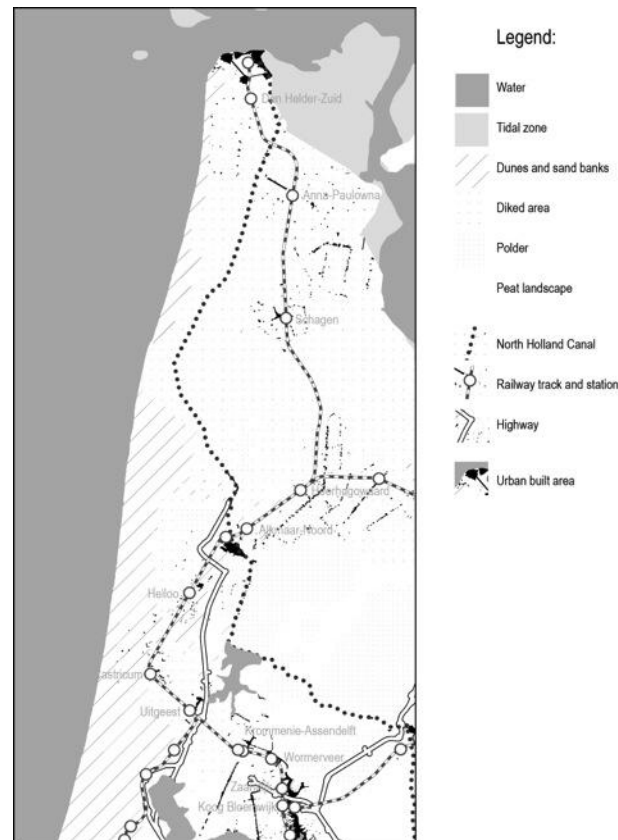

Figure 1. Landscapes and infrastructures in ‘Noord-Holland’.

Instead of using the predictive values now, in the ‘Vlinder’ model the desired direction of development is stated with the existing values as a starting point. How this goal is to be achieved is not elaborated, but it is suggested that a certain percentage of 50% of the future extensions should be within the railway locations and that this could be realised through a restrictive directing policy. The partially liberal oriented provincial Parliament endorses the aim for the 50% but the method of restrictive intervening policies is not accepted, it proposes a more detailed study on the matter. This research aims to identify the key factors in urban change in relation to proximity to transit for understanding the processes involved to develop possible grip on the matter. What are the driving forces in allocation of new development en how does this relate to the Transit locations. By mapping the area historically since the commencement of transit and through spatial analyses the critical changes are identified for *TOD*. The processes underlying these critical changes will be studied and placed in their context. It is of interest to illuminate the dynamics in allocation towards the transit locations. The province now concentrates its policy on a section of the railway line Amsterdam to Den Helder. This part of the line is subject to the ‘Program High Frequency Rail Transport, which entails an increase in frequency. This line is the subject of this paper. For this study the most central locations, which themselves are centralities are excluded. The locations of Den Helder, Alkmaar and Zaandam are therefore not taken into account. Per location the urban developments are analysed relative to the transit location to indicate the dynamics of the development processes.

Historical development of the Railway line

The line, line 'K' was built between 1862 and 1869 by State initiative to make the Military Port of Den Helder better connected in winter times. In the context of the policy of King William I to perpetuate to Netherlands as a nation. In the first plan for the trace of the line ran over the sand wall. There is a deviation in two parts, in both the North as in the South it is partially placed further eastwards. The factors involved in the Northern part were the polder reclamations of land, some of which were built on private investment and which had influence stakeholders. These were able to influence the course of the track. (van Giffen, 2006), a number of places in the area of Kop van Noord-Holland got a railway station for this reason: Anna Paulowna, Schagen, Heerhugowaard. In addition on a more local level factors as suitability of the surface and the possibilities on acquiring the necessary land play, this last aspect was involved in the realignment in the South.

The railway is opened in parts between 1867 en 1869 with 14 stations and 8 stops in the early stages. (Jonckers Nieboer, 1938). In the 1920s in public transport the bus rose and years of heavy losses for the railways followed, as a strategy to overcome this the railway company focussed on longer distance transport (Cavallo, 2007) this led in the area to the closing of 7 stops and 1 station. (Jonckers Nieboer, 1938). The places that already had a certain volume and or that by the arrival of the track had come to fruition stayed open those with lesser size were closed.

As a result of the large-scale developments in the area due to the postwar spatial policies the coverage on the line scattered from 38.5% in 1970, to 23% in 2010. The coverage is the percentage of inhabitants in a municipality that lives in a railway location. This is calculated with data from the report '22 stationslocaties Noorderkwartier in Kaart' (Engel, 2011). Already in the late 1960s it became clear the coverage was decreasing. and policies started to develop to link stations to extensions. In the 80 's a policy started to opened stations on areas that happen to be besides the railway track. (Cavallo, 2007).

Analyses on the developments on the Railway locations

In this paper per location the urban developments are analysed relative to the railway location and it is indicated what were the logics. For this the historical Topographical (Military) Maps of the area that go back until the middle of the 19th century are studied and the developments are mapped. The resulting maps show the developments in periods corresponding to typo morphological characteristics. The periods are: up to 1850, 1850-1910, 1910-1940, 1940-1970, 1970-2000, 2000-2010 (Engel, 2005). In this article the locations are grouped by type of landscape they are situated in; the Northern Coastal landscape, the landscape of sand banks parallel to the coast, the peat landscape with the Zaan. (Figure 1).

The 'Kop van Noord-Holland' area, coastal landscape

At the construction of the track between 1862 and 1867 the rail and the station were established between the settlement of Den Helder (1) and the eastern thereof located Military Warf (2). By its unique position as outpost on the sea the harbour of Den Helder has acquired the status of main Military Warf. A fortification was situated around Den Helder and the Warf. In the period after the construction of the track to 1910 there is only growth around the yard, in a strip of 700 meters around it (3). The station is located in this area therefor spatial developments and transit were linked. The yard got a growing number of activities assigned from national governments. By 1940 the whole area within the fortifications was build up. In the period after WWII new locations outside the fortifications were built in the 'satellite' quarters 'Nieuw Den Helder' (4),

and 'de Schooten' (5). A 'finger structure' of green areas between the satellites comes to the fore. After 1970, the district of Julianadorp is built remotely. In the 80 's from the policy of the railway company of opening stations to the recently expanded areas, at the quarter situated east of the railway track 'de Schooten', the station of Den Helder-Zuid was opened. By its peripheral situation and the halting growth of the Warf, the area is faced with a low demand for building production. Starting from early 80 's at the vacant East side of the track, an artist established a sculpture park and more recently in connection a nature reserve is developed (6), both in the green zone and both with spatial permanence. Further on the East on quite some distance (0.5 km) a business park 'Dogger-Dirksz Admiraal' (7) is developed. The district of 'de Schooten' is well disclosed, but the location itself is only half utilized.

Figure 2. Railway location Den Helder-Zuid.

The Anna Paulowna polder, in which the station is located, was between 1845-1847 reclaimed through private funding. The goal was to acquire agricultural land for exploitation in the sea mouth of the Zijpepolder. (bron) In 1865 the railway track between Den Helder and Alkmaar was inaugurated and the station was Anna Paulowna was opened, as described above it had a political cause. (Haarlem) The station was situated between the two settlements present within the polder; the core of 'Kleine Sluis' (1) and the hamlet 'Gelderse buurt' (2). 'Kleine Sluis' stemmed from the former harbour in the sea mouth of the Zijpe polder. The developments from the opening to 1910 take place at the railway station location towards 'Kleine Sluis' but merely around core of 'Kleine Sluis'. in the period between the two world wars, there are almost no developments in and around the cores but especially in the polder itself around Breezand (3). By the emergence of bulb cultivation from South of Holland, the land was suitable and cheap. For this reason the Stop of Breezand is opened in 1914, it is closed in 1938 when the railway company focusses on transport at longer distances. The post-war developments are only around 'Kleine Sluis', outside of the railway location, first the district 'Nieuwe Sluis' and subsequently around it 'de Elshof' (4). This development arrived now at the railway location. Since 2000, there are also developments West of the track in the form of business park 'Kruiswijk' (5). The combination of centrality of functions and the good car connection in the N249 road at 'Kleine Sluis' is stronger for attracting developments than that of the transit location with less further functions. The area is peripheral and has a low density, the car is the ideal means of transport.

Figure 3. Railway location Anna Paulowna.

Figure 4. Railway location Schagen.

The station opens in 1865 and is located east of the core of Schagen (1) that is at the junction of three roads. Schagen is situated within the Westfriese Ommeringdijk, an area that has been protected from the sea as early as since the 11th century. To 1940 the development is mainly between the station and the existing core (2). In 1937, the port of Schagen (3) with the canal 'Stolpen-Schagen' (4) is yielded with the purpose to give access to the North Holland Canal. The harbour was politically very desired, but quickly proved an outdated means of transport. (BRON) This project also includes the road connection on the N9 (5) in the direction of the main cities in the area; Den Helder and Alkmaar and the construction of the local roads 'Westerweg' (6) and 'Zuiderweg' (7). Until 1960, the spatial developments are largely focused on the station area (Koningshuisbuurt) (8), but also close to the newly established car connection (Ambachtenbuurt) (9). Schagen most grown between 1970 and 1980; from 7,310 to 16,761 residents. In the years to 1970 the extensions are mainly outside the station location, in the North in Nesdijk (10) and Groeneweg (11), due to the good car accessibility, while at the same time sites closer to the station site were available. In the beginning of the 80's remotely from the station the most Northern part of Groeneweg is finished. In 1977 on the southern side

of the village a road connecting with Alkmaar N245 (12) is established, consequently the district of Waldervaart (13) is developed, with a focus on automobile transport system and outside the station location. The area to the east of the track all this time for housing untouched. Only in the 80's, as a consciousness of mobility problems arises, the development closer to the station starts with the district 'Muggenburg' (14) and mid 90's 'de Hoep-Zuid' (15) located directly at the train station. After 2000 and end in 2010, the district 'Hoep-Noord' (16) is developed.

The 'Kennemerland' area, landscape of sand walls

Heerhugowaard originates from the 17th century by reclamation of the Lake on private initiative. The structure of the polder is with a middle road and in parallel two main canals. Regents of Alkmaar had to grant permission for the project to be executed. Around 1850 the built area is along the South-North connection routes, mainly on the Middenweg (1). The track is placed parallel to the West side of the Middenweg, it runs through new share and the course is adapted to the possibility of exploiting the parcel boundaries. The station is placed at the point where connection was to Broek op Langedijk, a village with an important auction. At the same time a road from the station to the Middenweg, nowadays the Stationsweg (2), is created. In the period after 1865 to 1910, the only development is along the existing roads. Between 1910 and 1940 the Stationsweg gets occupied. There is a tremendous growth between 1940 and 2000, from 5.315 to 44.248 inhabitants, as a result of the growth poles to policy. After 1960 the huge urbanisation starts and Structural plans are made to accommodate this. A facilities core is appointed at Veenweg (3). In the plan of 1968, de Ooster (4) en Westertocht (5) are to be held as boundaries and there will be a new core shopping center on the South side Middelwaard (6). This is the new focal point of further development. From here further development will take place in the South (7). In the structure plan of 1981 the Strip South of the track is designated as zone for facilities clustering (Beveland) (8) and the station square (9) is developed, this should strengthen the position of Middelwaard as centrality. The developments at Heerhugowaard evolved around cores of facilities, at a later stage in the early 1980s the railway station area was involved in the plans. Because of the enormous population growth, build in low density around a nucleus of facilities, there has been an exceptionally low coverage of 9%.

Figure 5. Railway location Heerhugowaard.

Alkmaar begins to grow significantly in the 1950s whereas it is designated as overflow area and growth core for Amsterdam. Between 1940 and 2000 its population grows from 33.837 to

92.836 inhabitants. Caused by national policies to relieve the pressure on the Randstad Alkmaar gets the task to accommodate a huge population growth. The required developments will be related to car infrastructure which is simultaneously developed. Between 1940 and 70 the extensions take place around the existing city and are to the car bypass 'de Ommering' (1) (De Hoef (2), Overdie (3), Veiling (4), Industrierrein (5), Oudorp Oost (6) en Oudorp West.) (7) between 1970 and 1980 On the north side mainly related to the then delivered N245 road to Schagen (8) and N242 to Heerhugowaard (9). quarters of Bergermeer (10), Huiswaard I (11), de Horn (12) en 't Rak (13). In 1980 the railway companies policies were was to open railway stations to newly delivered districts, in Alkmaar in this context the station 'Alkmaar-Noord' is opened. It is situated next to the then western of the track neighbourhood 'Huiswaard II' (14) which was just completed. Both spatial developments are not very related to each other. On the East side of the station a sports complex, the North Holland Canal and a park 'Oudorperhout' (15) are situated. Half of the railway location consists of uninhabited area. The area of Alkmaar is almost completely related to car infrastructure infrastructure and has a very low coverage of 18% in 2010.

In 1850 the area of the railway location of Heiloo consists of the two cores of Oekdom (1) and the more important Heiloo (2) a core with some facilities. By its situation on a relatively narrow sand wall Heiloo has a parallel North-South road structure, the Kennemerstraatweg (3) was an important connection between the major cities of Haarlem and Alkmaar in the area and paved. The railway station (1867) was situated at Oekdom to facilitate the local horticulture. After the advent of the tramline Haarlem Alkmaar over the Kennemerstraatweg, Heiloo became a commuter village for rentiers of the region of Alkmaar. It had in the area a particular forested area on sand wall. The spatial developments until 1910 occur on the exiting road structure. In the period to 1940 the main developments are between the two cores. The areas within the road structure between the centrality of Heiloo and the station (4) are completely filled in. Subsequently in Heiloo's period of main growth; from 1950 to 1960 the rest of area in the railway location, within the road structure (5) is build. Thus, in 1960 the railway location is almost filled and it begins to build the first areas outside. It starts outside of the railway location around the core of Heiloo with plan East (6), and in the middle 60's on the other side of Heiloo; Egelshoek (7). Afterwards the developments are directly outside the stations location with plan West (8) and in the 80's that of 'het Die' (9). Heiloo does not have its own exit on the A9 highway, in the new appointments in the 'Program New Sand Wall' (plan Zuiderloo) evolves around this. The location of the plan South of Heiloo is perfect for a new railway location but with the focus on the missing linkt to the highway there are no plans for this. Additionally impacts the paradox that by the 'PHS' more stops are more difficult to realize. (Maakplaats, 2013).

Figure 6. Railway location Alkmaar-Noord.

Figure 7. Railway location Heiloo.

Figure 8: Railway location Castricum.

Castricum developed at the Kennemerstraatweg (1) (the connecting road from Alkmaar to Haarlem) at a small church. Buildings around this church with square the core of Castricum in 1850. The railway track is to on the West side of Castricum and makes a turn and is situated east along the other core of Bakkum (2). The railway station is placed at the curve in the track at the core of Castricum. Until 1910 there are almost no spatial developments, except at the psychiatric hospital Duin en Bosch (3) at Bakkum, which are entirely outside of the railway location. From 1910 to 1940, the population increased from 2813 to 8412. The urban extensions are primarily at Duin en Bosch and around the core of Castricum the latter is in the location. In the period after 1950 the both cores extend and further on with the Oranjebuurt (4) and Zeeheldenbuurt (5) the cores grow to each other.

The earlier developments in Duin en Bosch have influence on the further development in this period, the extensions are situated between the two cores. Proximity of existing urban territory is important for the allocation of new buildings in this period. Afterwards to the East a development starts of Molendijk (6) en Noordeind (7) which is not linked to existing territory these are completed in the early 80 's. West of the track almost no developments are taking place. When in the 1990s in general the development of building on 'the other side of the track' starts in Castricum this side with its particular landscape protected by law. By this not to be occupied area and by the developments around Bosch en Duin the site has the low coverage of

15% in 2010. Opening a station at Bakkum could improve this, there in an earlier period both sides of the track were built.

In 1850 Uitgeest was a ribbon (1) composed of the Middelweg and here directly parallel to Westergeest, with a core at the junction with the road to Castricum. The village lies on a sand wall. At Uitgeest two railway lines join, from the Zaan area and from Haarlem. The station is placed where they are joined and tracks are placed on the southernmost point of the Ribbon on a firm distance of 1 km. The station is located east of the Ribbon, Western would not have fitted in connection with the Assumervaart. (2) Until 1910 the building expansion only took place at the main core which is outside of the railway location. Afterwards the Hogeweg (3) is constructed up to 1940 the build finds place here. Also there is some ribbon development South of the station. Both developments are mainly in the railway location. In the early 1960s the start of with industrial estate Dorregeest (4) North of the old core. It is situated close to the Uitgeestermeer and the A9 motorway. This area continuous to develop until now completely outside the railway location but with excellent connections. Around 1960 the Geesterweg (5) was laid out right in front of the station, West of Hogeweg in the 10 years until 1971 the area around this road is built related to the railway location. The location to the North of the track becomes completely filled in and the following development is North of the location in the southern part of the district 'de Koog' (6) early 80 's the whole area of 'de Koog' is completed, largely outside the railway location. To the early 90 's the mainly building activities are on the 'other' side of the track, the beginning of the quarter 'de Kleis' (7), this is related to the rail. The great distance at which the station was placed to the original core of Uitgeest and the late crossing over the track in the South is to large part of extentions outside of the railway location.

Figure 9: Railway location Uitgeest.

Railway locations in the peat landscape of the Zaan area

The track is placed immediately south of the ribbon of Krommenie in the middle of the peat landscape. The center of Krommenie (1) is situated north of the station on the border of the railway location. It is situated at the crossing road to Uitgeest and the one to Wormerveer. The station is immediately West of the Ribbon, as on the East side is the Nauernasche Vaart (2), an important access for Krommenie. In the period up to 1910 extensions in particular find place at the core towards the Nauernasche Vaart this concerns housing and industry, further expansion from this development along the Canal continue in all the periods to follow, manly industry. From the first to the second world war the further building is mainly around the core and also a bit on the road directly opposite the station (Stationsweg) (3) which is constructed and building at the ribbon southward. Between 1950 and 1960, the area around the Stationsweg is built up to

the Fortuinlaan (4). There is also some small development South of the track, east of the ribbon. These developments are related to the station. In 1960 the new area to be built comes to lie entirely outside the location with Rosarium (5) which is the Northwest. The areas of Noorderham (6) and Zuiderham (7) follow and are completed in the late 1960s. Only as of 2005 the extensions continue with locations south of the track in Saendelft (8). Between 2006 and 2008 the station is replaced 400 m to the West. The link with the existing core is completely lost and the location is now connected to Zuiderham, the field of Fortune Avenue and the new district Saendelft South of the track.

Figure 10: Railway location Krommenie-Assendelft.

Railway locations along the Zaan; the Railway locations of Wormerveer, Zaandijk and Koogbloemwijk

Figure 11. Railway location Wormerveer.

Around 1850 the build in the area lies mainly on the dyke along the Zaan, line-shaped and stretched out, some distance away parallel the track is constructed. On a number of places in the ribbon there are concentrations in development.

The station (A) is located South to the core of Wormerveer (1), which is at the junction with the dyke at the Zaan (2), the road to Krommenie and the ferry to Wormer. The station is located east of the 'Karnemelkssloot' (3), a water connection to the peat landscape of Westzaan. Until 1910 in particular the surroundings of the station and concentration of warehouses (4) on the

Zaan further East are built. To 1940 almost the entire area between the track and the existing buildings is taken, everything in reach or transit. Starting in the mid-1950s, a stand-alone expansion to the North from Wormerveer in the Polder Westzaan which is completed in 1970 (5). This lies entirely outside the location. Only after 2010, the rest of Polder Westzaan constructed with industrial estate (6).

Figure 12. Railway location of Zaandijk and Koog Bloemwijk.

In the area of the railway location Zaandijk (1) and of Koog Bloemwijk (2) the concentrations at the dyke area at: Sluissloot (3) Zaandijk (4), the road to Westzaan (Guisweg) (5), Koog aan de Zaan (6) and at the Mallegatsloot (7). The station of Zaandijk (1869) is located between the Zaandijk and Koog aan de Zaan, exactly South of the Guisweg the connecting road to Westzaan forms. The station serves these three settlements. Until 1910 the building activities are at the Guisweg, the new road to the station and around the existing concentrations. In 1920 West of the track the quarter of Rooswijk (8) was developed parallel to the Guisweg. Until 1940, the area between the track and the Zaan became largely occupied. In 1931 the station of Koog Bloemwijk (2) was opened adjacent to a residential area (9). In the early 1960s from Rooswijk the district of Rooswijk (10) was started this development carries through to 2000. The driving force was the major at that time, it is the first major development West of the track. At the end of the seventies the station Koog Bloemwijk the district of Westerkoog (11) is developed.

Conclusion

Characteristics specific of the location in the field of spatial quality within the territory can cause spatial developments. Mobility provision through infrastructure has the same property. Especially between 1910 to 1940 the station has a rebounding effect for spatial development. Cores with facilities and centralities also have this feature, perhaps to a greater extent than the station. The developments begin here earlier and are larger. The locations where station and core are competitive show that a core with facilities exercises on developments more attraction than the station. By 1960 most railway locations are full and the areas outside it follow. While paradoxically the still undeveloped side of the rail often remains unoccupied. This phenomenon also confirms that the proximity of facilities and other built-up area are stronger than the station. After the beginning of the 60s the developments become more independent. The combination of centrality and mobility provision has a very strong rebounding operation for spatial development. If the distance between core and station is larger this has a negative impact on the

coverage. The trend of building outside of the location is intensified during the 1970s and 1980s. Simultaneously in the 1980s a development starts of opening of stations where rail is close to urban extensions, this shows a starting consciousness about the relationship transit and urban development. In the 90 's starting to occupy the unused side of the track. The shape of the station and its disclosure can affect the spatial development and level of orientation of the future urban territory to transit. The cases of Alkmaar, where a ring road forms the carrier of urban development and the Zaan area where the line shaped rail is the carrier of spatial development compared to show the structure of the infrastructure influences the relation transit to urban development.

Managing the mark of the memory: a case study on the North Dublin Victorian fringe-belt

Mariana Moreira

MosArt Architects (Architecture, Landscape Architecture, Urban Design), Block 6, Broomhall Broomhall Business Park, Wicklow, Co. Wicklow, Ireland. E-mail: mariana@mosart.ie

Abstract. *The urban fabric can be regarded as a repository of human life that records past culture and includes historic-geographic changes that have physical manifestations, but that are also underpinned by processes, whether social, economic or political (Whitehand, 1977). Notwithstanding the fact that much of the urban fabric is worthy of conservation, research indicates a general paucity in understanding among planning authorities of urban morphology and the morphological nature of the city that results in weak or inadequate conservation planning policy and systems more focused on buildings and plots than their integral role in terms of urban form in larger urban tissues (Whitehand and Morton, 2004). As a pretext for demonstrating the nature of urban form as an organic whole comprising parts that are interrelated in form and historical process and the failure by decision makers to recognise and appreciate this, the northern intermediate fringe belt in Dublin City is taken as a case study. The study involved a morphological analysis of both the preceding Georgian city and the Victorian fringe belt, examining both the historical processes over the two centuries concerned and the resulting and contrasting urban form. To date, however, in the planning system in Dublin City Council, there is no recognition or appreciation and, thus, management of the intermediate fringe belt. Hence, this clearly identifiable urban tissue that bears witness to a significant period in Irish history is open to insensitive development, especially with concerted urban policies concerned with compaction and densification (Rudlin and Falk, 2009). The likely ensuing loss of significant parts of the urban fabric surely poses a major threat to our future cultural heritage as constituted by the city.*

Key Words: conservation, fringe-belt, Dublin, Georgian Era, Victorian Era, planning

Introduction

Urban Morphology – the solution for urban conservation planning

It has been recognised that planning policy concerning conservation tends to focus on buildings and their immediate settings and not on the city-wide scale (Jokilehto, 2010; Prunty, 2010; Whitehand, 2010a). But, clearly, concern for the historical integrity of the city as a whole must involve the city-wide scale perspective and its interrelated parts (Slater, 1984). Moreover, the problem of the weak relationship between research and practice is widely noticed as well as lack of cross-disciplinary awareness of relevant research (Whitehand, 2012). The consequences, whether potentially or actually, of the present approach is the damage or loss of significant parts of historical city fabric along with the resulting compromise of the associated historical record of city growth regarding form making. The likely ensuing loss of significant parts of the urban fabric surely poses a major threat to our future cultural heritage as constituted by the city

There is in Ireland, currently, an apparent failure among common decision-makers who determine planning to fully appreciate the city in terms of its morphological constitution that includes its historic-geographical significance and involves the study of urban form (Kealy and Simms, 2007).

Fringe Belts

The urban fabric, comprising parts of the city and their spatial relationships, changes and cities expand, so engendering a shifting periphery that becomes a repository of the urban

morphological history in regard to urban pattern and function and effectively recording the stages, physical and social nature and process of city growth. Typically an important integral component at a whole-city scale of such change is the urban fringe belt, whether inner, intermediate or outer. These belts not only demarcate particular eras and geographical regions of urban expansion, but also comprise a particular character type reflecting land use as well as socio-economic state. They are, therefore, culturally significant.

Morphological overview of Dublin: origins and growth

Dublin is the location of the case study of this paper and is used to demonstrate the limitations of current planning policies in regard to conservation at the urban scale. For this reason a brief overview of the origins and early growth of the city is provided here.

The origins of Dublin as an important settlement dates from the end of the 9th Century when the Vikings, spreading across the Irish Sea, first began to use the site as a base for their operations (Haughton, 1949). During the 10th and 11th Centuries, this settlement developed into one of the most important coastal trading station within the Viking trading-network (Simms, 2001).

In the late 12th Century, after the capture of Dublin by the Anglo-Normans, the town reduced in status from a semi-independent Viking kingdom to a medieval English borough under the Henry II. Only a few major medieval buildings have survived (Simms, 2001). The Anglo-Normans brought to Dublin a reliance on the institutions, which supported urban life. They also set about land reclamation, particularly on the southern bank of the River Liffey. The medieval street-pattern has survived to a greater extent, judging by depiction on the earliest surviving maps of Dublin: John Speed's map of 1610 and John Rocque's map of 1756 (Simms, 2001). During this period Dublin began to be dominated by squares and streets forming an urban coherent network of spaces and axes. The 19th Century, however, was marked by deep economic crises, which was reflected in the city fabric, particularly in respect of institutional urban fringe belt on the periphery of the Georgian city.

In the mid-19th Century the Dublin Corporation was established making the first step towards the creation of a single authority with comprehensive responsibilities. However, this body was not given the necessary resources and powers to be able to act effectively to respond to the difficulties that the city was experiencing, in particular the problem of slums between 1800-1925 that revolved around a number of key issues, such as tenement accommodation, overcrowding and moral degradation, the policing, control and relief of the poor by both state and charity organizations (Prunty, 1998). Improvements were characteristically piecemeal, without a broad based integrating mechanism or plan (Prunty, 1998).

The lack of cohesive plan for the city in the early 20th Century continues today at least regarding the historical heritage: 'Dublin must be one of the few European cities where the destruction of eighteen-century and earlier fabric is still accepted as a valid means of urban development' (McCullough, 2010: 28).

The adequacy of planning policy regarding urban conservation is clearly called into doubt in this statement. Rather, it can be deduced that there is an urgent need for a visionary and systematic planning and development approach. A case is made in this paper for an urban morphology-based conservation planning methodology that establishes an appreciation of the past as reflected in the present physical and social fabric and which, more pragmatically, provides tools for both analysis and decision-making for the future.

Case study: North Dublin intermediate fringe-belt

This section will review briefly the historical context of the original city wall with the adjacent extramural zone as the inner fringe belt and the ensuing urban growth up to the Georgian era of

the 18th Century and subsequent decline. The intermediate fringe belt starts to emerge from the late 18th Century and can best be recognized in juxtaposition to its surrounds and in the distinctive process of its formations. For this reason, urban development of the northern part of Dublin City during the booming Georgian and the recessionary Victorian periods, respectively, are paid similar attention. Moreover, given the strategic role played by the Wide Street Commissioners in the shaping of the city, particular attention will also be paid to decision making as recorded in minutes and how their work adapted to the troubled transition period of the end at the 18th Century and the early stage of the 19th Century.

Dublin's Early Fringe Belts: Inner & Intermediate

Inner Fringe Belt – instigated by the City Wall

The city wall was built to function as the primary system of defense. The wall had to ensure its own survival under attack. Generally, it was raised on rough terrain, seeking to maximize the advantages of natural features of defense (Kostof, 1991). Such is the case with the River Liffey in Dublin, which flowed along the northern edge of the city wall. The town plan of Dublin preserves many clues to its morphogenesis which, when analysed together with historic maps and other documentary sources, allows the reconstruction of the medieval street pattern (Prunty, 2010) as well as outer wall street systems. The map below (Figure 1) illustrates the overlap of the medieval Dublin from c. 840 to c. 1540 over a 1939 Ordnance Survey map.

Dublin's inner fringe was occupied by churches of religious orders with their associated lands and buildings, as well as institutions (Prunty, 2010). In the early 1600's migration of refugees fleeing from an economic slump caused by wars and harvest crises, clustered together in 'cottages' or shanties on the fringe area, so presented a serious threat to urban stability and order (Lennon, 2001).

Figure 4. 1798 William Wilson map (Source: www.dublin1798.com).

Dublin Victorian/Intermediate Fringe Belt Formation

Due to fundamental political change in Ireland at the end of the 18th Century and the beginning of 19th Century, an economic slump occurred. This, in turn, brought urban expansion to a standstill with the consequence of the area at the edges of the city becoming open to institutional development. Hence, fringe belt formation began along the canals. With subsequent expansion this zone became embedded in the urban fabric so establishing an intermediate fringe belt.

Similar to the inner fringe belt, the intermediate belt is associated with fixation lines, in this instance comprising the canals. When compared with the inner fringe belt, however, our case study area tends to be less continuous in space, have fewer contiguous plots with more open ground and vegetation cover and a sparser street pattern (see Figure 5).

The map below (Figure 5) illustrates the approximate position of the original city wall and the intermediate urban fringe belt along and beyond the canals of the city of Dublin in 1948.

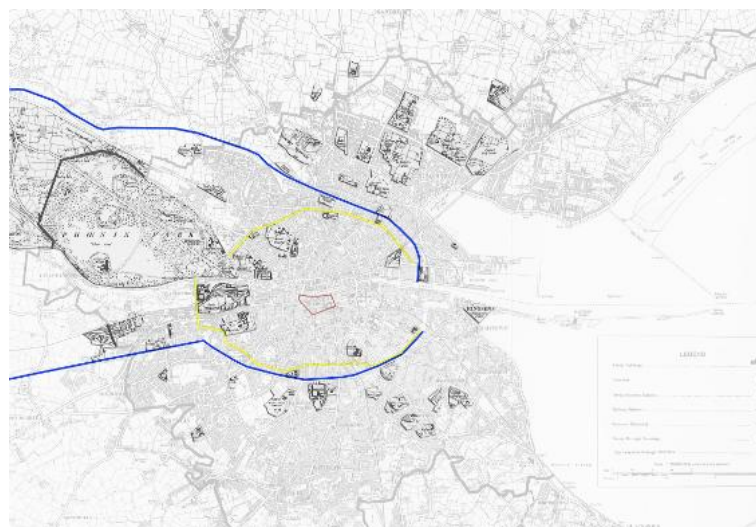

Figure 5. 1948 OS map highlighting the typical fringed belt plot uses (source: Richview Map Library) (blue line – Royal and Grand Canals; yellow line – North and South Circular Roads; red line – original location of city wall).

A more detailed map analysis later in this paper will focus on the intermediate fringe belt with its fixation line and surrounding use patterns, urban tissue, block and plot sizes. However, before examining this fringe belt in detail, it is necessary to understand what preceded it in terms of urban development and its cultural, economic and social context that generated the urban fabric of the 18th Century Georgian era.

Urban development in the North Georgian City as a coherent vision

The 17th Century occupation of Ireland by many who served in Oliver Cromwell's armies could only be achieved through massive confiscations of lands, with the existing freeholders being turned out and transplanted to other areas of Ireland or forced to emigrate. The settling of Ireland by these soldiers and the ensuing peace stimulated the economic development of the country and, so, a considerable level of prosperity was experienced. This was reflected by an increase in building activity throughout most of the country (Loeber, 1973).

The powerful agents of growth of the last quarter of the 18th Century are characterised by different factors. One is the free trade concession won by 1780, allowing the removal of foreign trade restriction. Another significant factor was the economic concessions granted to the Roman Catholics: as Catholics were excluded from politics and from many professions, commerce was their main occupation, which significantly increased the wealth of some. The concessions made in 1778 enabled these Catholics to speculate in buildings and lands and to participate in urban development (Burke, 1972).

Moreover, the independent status of the Irish parliament gained in 1782 made Dublin the place where functions that were previously performed by the House of Lords in London now devolved in the Irish House of Lords in Dublin. This growth determinant gave great prospects of a permanent resident legislature with growing administrative bodies, which, in turn, increased speculative investment in upper class residential buildings (Burke, 1972).

The 18th Century Georgian Dublin City growth pattern, notwithstanding the underlying rectilinear geometry, manifested a disparate structure caused by the power of those who owned parts of Dublin and reflecting a piecemeal individualisation of control as distinct from being based on a coherent overall vision that is determined by, say, a single mind or by the common good. Thus, development comprised speculative terrace housing on a patchwork of small independent land holdings (McCullough, 1989; Sheridan, 2001; Twomey, 2010). Notwithstanding, as explained by McCullough (1989), unity was attained, if not at the city scale, at least in regard to building architectural style materials and elevation classical proportions.

The 18th Century streetscape of Dublin was produced by private landlords who developed large tracts of land, the most noteworthy being the Gardiner family (later Barons and Viscounts Mountjoy) on the north-east side of the river, and the Viscounts Fitzwilliam of Merrion on the south-east. Common practice in street and square planning at the time involved the owner providing a plan of the plot-series layout as a guideline, each plot then being leased for development to architects, builders, speculators or private individuals whose buildings were controlled by clauses in those leases. From the second half of the century the control of such development became concentrated in one planning body – the Wide Street Commissioners who had the power of consent the approval for development or transformations of any part of the cityscape (Sheridan, 2001).

The part-to-whole relationship

The schematic axonometric of Mountjoy Square shown in Figure 3.6, illustrates the typomorphological hierarchy commonly found in Georgian Dublin. Starting at the larger level, this hierarchy comprises an urban tissue (from service lane through plots and square to opposing service lane); square and street/plot series, individual plots and buildings (main house to the

front with a front area, facing the street and square, and coach house to the rear facing a service lane) (McParland, 2010).

Figure 6. Part-to-whole: a plot within a plot serious on the north side of Mountjoy Square . (Source: Trinity Map Library).

Figure 7. 1875 OS map extract (not to scale). (Source: Trinity Map Library).

This analysis demonstrates the complex hierarchical interdependence of the different levels of which the urban fabric is comprised. It is clearly useful for morphological description but also, as we shall see later in this paper, as a powerful planning tool. As affirmed by Kropf (2001b), this methodological tool also provides a basis for urban character identification: ‘Whatever the element, an entire street or a single wall brick, the design of the element is a matter of both the objects that compose it and the relationship between them’ (Kropf, 2001b: 14).

The Wide Street Commissioners – the main decision makers of Dublin - Late 18th Century (aspirations/rise) to early 19th Century (decline).

In 1749 a parliamentary committee was appointed to find out the causes of traffic congestion on Essex Bridge, which was clearly blamed by the fact that there was no other easterly bridge to

serve the spreading city to the east. In 1757 the House of Commons appointed a committee to examine how best an avenue from that bridge to Dublin Castle might be opened. Eventually twenty-one Wide Street Commissioners (WSC) voted for making a wide and convenient way, street and passage from Essex Bridge to the Castle and subsequently received royal assent on 29 April 1758 (McParland, 1972, 1986). The 1757 Act and the 1758 royal assent empowered the commissioners to summon a jury to value the property needed to open a new street, this property was subsequently bought under their powers of compulsory purchase (McParland, 1972; Sheridan, 2001; Boyd, 2006).

During the first half of the 18th Century development in Dublin is marked by uncontrolled physical expansion and lack of continuity between the old centre and the new surrounding suburban area (Sheridan, 2001). The second half of the 18th Century is marked by a radical change characterized by a concerted drive towards an improved Dublin City, derived in part from Enlightenment principals of civic life expressed in new public buildings. This was realised most effectively in the work of the WSC and, in turn, caused changes in the social, economic, geographic and architectural realm of the city (McParland, 1986; McCullough, 2007).

WSC and the Royal Canal Company Affairs

By the last decade of the 18th Century, the Royal Canal and the Grand Canal together already encircled the city. The attention of the commissioners was pointed to the northern fringe of the city by the works required to the Royal Canal. Although the canals lay outside the circular road, they became part of the WSC jurisdiction after the 1792 Act, which extended their control half a mile beyond the circular road. The resulting encompassing of the city in effect delineated a metropolitan area and, thus, a metropolitan planning authority was created. Thus, for the first time, the development of Dublin could be said to be under the jurisdiction of a single unified authority (Burke, 1972; Fraser 1985; Sheridan, 2001): 'Read the Resolution of the 1st July 1791 relative to the expediency of having a correct Map of this City – and by an Act of this session the powers of this Board be extended for half a Mile beyond the Circular Road.' (WSC minutes book 10: 316).

Figure 8. Map of the vicinity of the North Circular Road, showing Drumcondra Road, Binns Bridge (Source: Dublin City Library WSC/Maps/237, date not given).

The following year, on Friday 10th May 1793, (present Right Honorable Lord Mountjoy) the commissioners 'Approved and signed a Map of the Interior Bank of the Circular Royal Canal,

and a short Street leading from said Street called Dunn Street, said bank to be Fifty six feet Wide and the Street Forty feet in width.’ (WSC minutes book 11: 279) (See Figure 3.8)

The WSC’s decline

From the 1790’s money started to run short causing delays in the WSC’s projects and site development progress. As this last decade of the 18th Century passed, an economic and social downturn was becoming more and more imminent, in particular due to the disturbed state of the country with political unrest occasioned by the United Irish rebellion of 1798.

After 1800 complaints of acute shortages become common in the WSC’s minutes. The United Parliament, resulting from the 1801 Act of Union, showed an unwillingness to financially support the commissioners’ work and this duly caused the post-1800’s decline. At the start of the new century, Dublin became reduced to a mere provincial city instead of a capital, as was marked by the various incomplete WSC’s projects. Having been active for over one hundred years, the commission was finally dissolved in January 1851 (WSC minutes book 50: 108-9).

The historical context of the intermediate fringe belt formation

The city suffered severely in respect of its economy, politics and physical development as a consequence of these dramatic changes. Examples of the diminution of the city status made physically manifest are, as follows: whilst Mountjoy Square retained its status during the first half of the 19th Century, it then gradually deteriorated due to the influx of rural migrants escaping and trying to survive to the Great Famine; grand urban plans for the Royal Circus comprising monumental and luxurious residential buildings had not yet been realised and in 1800 there are no signs of it having even begun; and the Circus became the site of the Mater Hospital in 1853. Another significant institutional development during the 19th Century, close to the Mater Hospital, was Mountjoy Prison, built in 1850 (Burke, 1972). During the 19th Century, a limited amount of money was spent in private ostentation whilst more was spent on improvements on urban infrastructures and public facilities as well as on some social housing for the poor that dominated Irish history of the post-Famine era (McCullough, 2007).

Post-Union Dublin lost her resident gentry and peers due mainly the disbanding of the Parliament and the consequent economic slump. The Georgian property of the political and social elite was extended, reutilized and subdivided, especially in the case of larger mansions, most of which were transformed from residential use to institutional use (McCullough, 2007).

Historic context of the Royal Canal Construction

In 1715 an Act of Parliament was passed which proposed to make a considerable number of rivers navigable and to link them with a series of canals. In 1788 the Irish Parliament introduced a scheme to help finance private companies to build canals, make rivers navigable and improve ports and harbours. Under this scheme a series of new navigations emerged in Ireland (Clarke, 1992). Among them was a re-vamped version of the northern river-canal, the Royal Canal, a navigation proposed in 1755. The Royal Canal, completed in 1817, links the River Liffey in Dublin to the River Shannon at Cloondara in Co. Longford (Delany, 1992).

The Royal Canal as a fixation line to the Northern fringe belt

Looking at a Dublin City map from the beginning of the 19th Century, the line where Dublin City officially ended can be identified along the North Circular Road. This line was extended outwards to the canals by the mid-century. In fact, this is confirmed on a map of Dublin City produced in 1837 (Figure 3.9) where the municipal boundary is delineated (purple line)

following for the most part the line of the Royal Canal to the north and the Grand Canal to the south. Accordingly, the two canals provided a clear-cut administrative area.

However, a more complex and less clear-cut form emerges when one traces the real extent of the built-up urban area. The north side of the Liffey, from Arbour Hill to Phibsborough was dominated by open fields, interrupted only by development around Prussia Street and a complex of institutions around Grangegorman. It is not surprising that the streets bordering these institutions typically included low-value houses or cabins (Prunty, 2001).

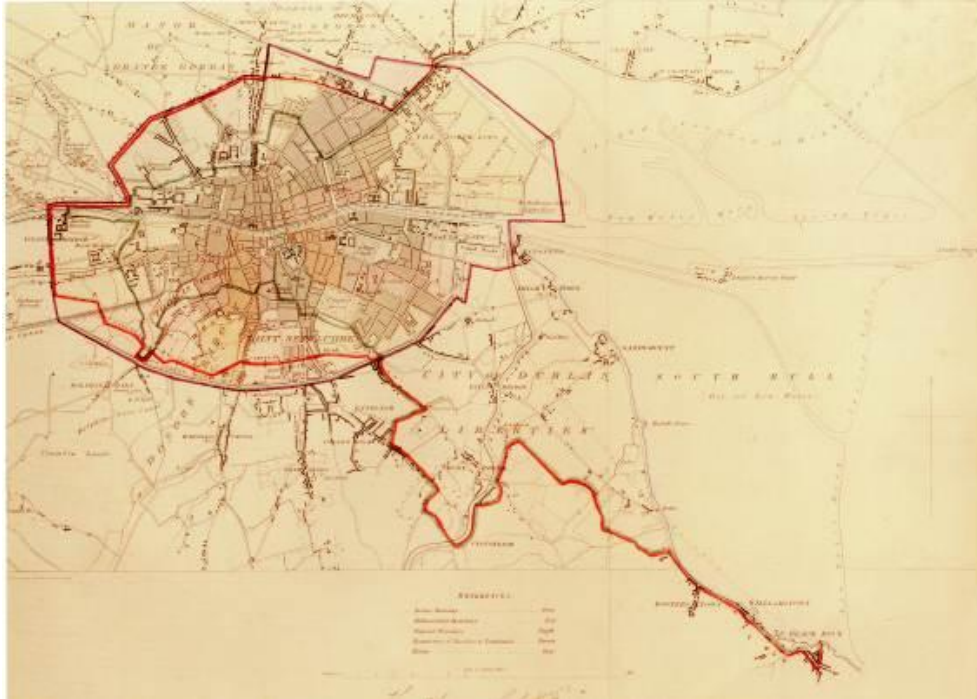

Figure 9. Map of the County of Dublin, 1837, by Thomas Larcom. Red line: Parliamentary boundary; Purple line: proposed boundary; Green line: ancient boundary (Source: Irish Historic Town Atlas).

Morphological development – the institutional fringe

The *History of the City of Dublin* two-volume book, written by Warburton, Whitelaw and Walsh in 1818, describes buildings and urban fabric of the city at the beginning of the 19th Century. A considerable part of the second volume is dedicated to several types of institutional buildings that are referred to in great detail. The location of those institutions tends to be at the edge of the city, thus gradually forming an institutional fringe as commonly emerges during an economic slump. There was a significant number of institutions along the North Circular Road outlined in the mentioned volume as follows:

1. Dublin Female Penitentiary was opened in the year 1813 and in the following year ‘was removed to a new and extensive building erected for the purpose on the North Circular-road.’ (Warburton, Whitelaw and Walsh, 1818; II: 775)
2. Asylum for old men in Russel-place was completed in 1812. ‘It stands on the south side of the Circular-road, near Mountjoy-square, in a pleasant and healthful situation’ (Warburton, Whitelaw and Walsh, 1818; II: 795-6)
3. Widow’s retreat: ‘... excellent institution was erected in 1815, at the sole expense of the Latouche family. ..., situated at the extremity of Dorset-street, in the open and healthy outlet of Drumcondra.’ (Warburton, Whitelaw and Walsh, 1818; II: 784)

4. Asylum for aged and infirm female servants: 'This institution was founded in 1809, ..., in the vicinity of the circular-road, in a situation healthy, cheerful and airy,' (Warburton, Whitelaw and Walsh, 1818; II: 790)

5. House of Refuge: established by a 'pious widow in humble circumstances ... engaged the concurrence of many opulent Catholics, and a spacious house was purchased in Stanhope-street, (Grange Gorman-lane), Forty females whose character and conduct entitle them to this protection, are here supported, and finally recommended to reputable services.' (Warburton, Whitelaw and Walsh, 1818; II: 793)

6. Female orphan house: 'In the year 1790, two ladies, Mrs. Ed. Tighe, and Mrs. Ch. Este, at their own private expence [sic], took a small old house in Prussia-street, and placed in it five female orphans. ... A subscription was opened the following year, which increased so fast that the present extensive building was erected, on the north Circular-road, The situation of the house is airy and healthy,' (Warburton, Whitelaw and Walsh, 1818; II: 849)

7. Newgate prison: this provides an example of a *fringe-belt translation*, that is, the transfer of a land-use unit from an older fringe belt to a more recent one. 'The old gaol in Corn-market (number 7.1 in the map below), called Newgate, from its having formerly been one of the city gates, being small, inconvenient, and from its ruinous state, insecure, it was determined to erect a new prison'. Later in the 18th Century building began 'in the Little Green, a piece of ground in the north part of the city, which was chosen, but we are sorry to add, very injudiciously, for its site, as it was not only insufficient in extent to admit of sufficient yards and other necessary accommodations for the different descriptions of prisoners usually confined in gaols, but environed by dirty streets, and in so low a situation as to render the construction of proper sewers to carry off its filth impracticable.' (Warburton, Whitelaw and Walsh, 1818; II: 1047)

8. Dublin penitentiary: 'The first stone of this large edifice was laid by the Duke of Richmond, in 1812, and it is proceeding rapidly to its completion. It is situated contiguous to the House of Industry, and presents its front to Grand Gorman-lane, which extends 700 feet.' (Warburton, Whitelaw and Walsh, 1818; II: 1061).

The institutions outlined above are mapped in Figure 3.10 below. The majority of these institutions are located along the North Circular Road, thus forming the north intermediate fringe belt.

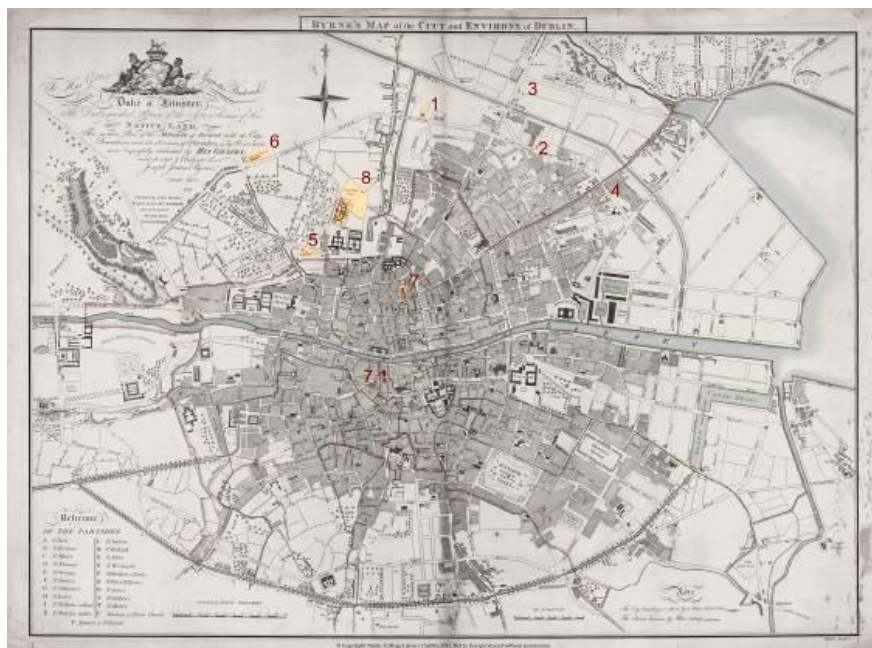

Figure 10. Byrne's Map of the City and Environs of Dublin, date 1819 (Source: Trinity Map Library).

From maps of north Dublin City dating after 1800 and throughout the 19th Century, there is little evidence of high-class residential development (Figure 11 and 12). Rather the predominant development type was that of institutional buildings, most notably, as previously mentioned, the Mater Hospital and Mountjoy Prison as well as the female penitentiary, asylum and orphanage.

The early 19th Century Dublin had inherited urban form and built fabric that varied immensely, reflecting its long and complex history. Street patterns had changed from the packed narrow lanes of the medieval city core to the orderly and uniform set pieces of the previous century landlord speculation on both sides of the river (Prunty, 2001).

Figure 11. 1821 Duncan Map (Source: Richview map library) (blue line – Royal Canal; yellow line – North Circular Road; 1 Phoenix Park; 2 Military Hospital and Royal Barrack; 3 Female Orphanage; 4 Richmond Penitentiary; 5 Female Penitentiary; 6 Whitworth Fever Hospital).

Notwithstanding the complexity the fringe belt form noted above, a diagram is provided below (Figure 13), adapted from the famous JWR Whitehand's 'Fringe-Belt Model', demonstrating an interpretation of morphological urban expansion layers that reflects Irish history.

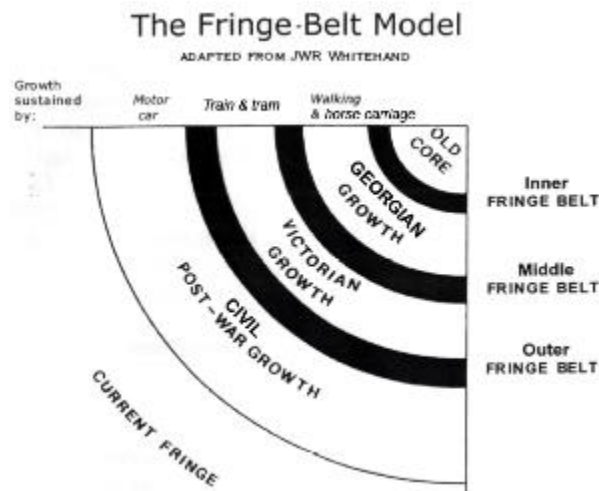

Figure 13. Irish version of JWR Whitehand's 'The Fringe Belt-Model'.

Manifestation of Institutional Expansion in Elevation

A study carried out by the 2009-2010 class taking the Masters in Urban and Building Conservation (MUBC) at University College Dublin (UCD), examining the north Georgian urban area of Dublin. This study included various street facades, one of which being the North Circular Road (Figure 14 and 15). In many instances plot series were mixed, with the original fringe belt pattern comprising relatively extensive plots with open spaces in between (Mater Hospital) facing more continuous compact lengths of terraced housing.

Figure 14. North Circular Road Street Façade (note the northern façade of terrace houses and the southern façade of both terrace houses and the Mater Hospital).

Figure 15. North Circular Road Street Façade (note the northern façade of the Mountjoy Prison and the southern façade of the Mater Hospital).

Urban morphology as a conservation tool - critical review of current and proposed Architectural Conservation Areas (ACAs) in Dublin

Looking at the current Dublin ACAs and the recently proposed ACAs, some points can be considered bearing in mind the Larkham and Morton (2011) study reflecting an overall lack of explicit consideration of morphological concepts of boundary-drawing.

One of the current ACAs is in the Thomas Street area, on the south side of the river. Figure 16 below identifies with red spots the protected structures within this area of the city and with a green line the boundary of the ACA. One can question why the south side of the boundary line outlined with a purple line, along The Coombe Road, was left outside the area given that it has similar morphological characteristics to the other side of The Coombe Road, as is clear from the photograph below (Figure 17). Again the street here is used as the boundary line, which surely makes little sense in terms of the actual constitution and coherence of the urban fabric concerned. Moreover, Cork Street, outlined in blue, is open to serious questioning regarding its design and location considering how it insensitively breaks historical and social links between the north and south of that street, namely the Liberties and Newmarket, respectively.

Boundary delimitations will continue to be an important activity of geographical urban morphologists and urban landscape managers due, not least, to the fact that urban areas undergo continuing change and, thus, require revision from time to time.

In any case, regarding boundary delineation, a thorough understanding of the historical and special structure of townscapes is a prerequisite for successful zoning and management of ACAs and, so, a thorough awareness of morphological regions is key to understanding the richness, community value and identity of the townscape of any particular urban area (Larkham, 1990). Only with such knowledge can the conservation challenge be scoped for present and future generations. Furthermore, such insight helps to identify areas at the urban scale worthy of conservation that comprise buildings and ground plan features that relate to each other historically and physically (Conzen, 1985). Conzen (1985) contends that ‘such ensembles form

the historically most appropriate units for conservation planning within the city' (Conzen, 1985: 75).

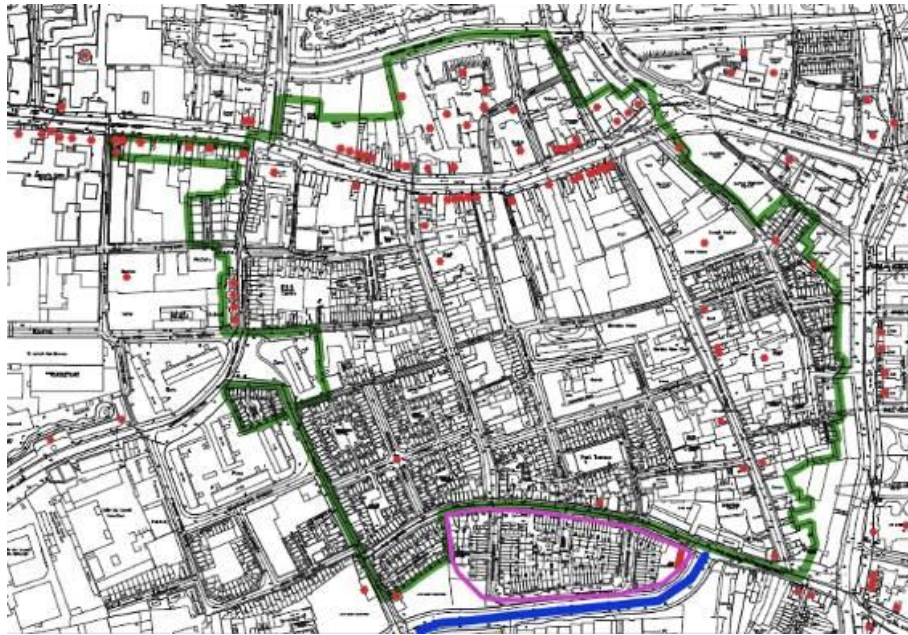

Figure 16. Thomas Street ACA map, boundary line in green, excluded area in purple, Cork Street in blue (Source: Dublin City Development Plan 2011-2017).

Figure 17. Photograph of the Coombe Road looking westwards.

Pressure for change

The lack of formal recognition and protection of fringe belts leaves them vulnerable to erosion and ultimate disappearance. Once a fringe belt is encompassed within the built up area rather than remaining on the urban periphery, it becomes subjected to most of the forces for change at work in any urban area which, in turn, depend in a large part on the existing character of the fringe belt regarding open space as well as the state of the economy regarding pressure for urban infill and densification. Within the compact city discussion, Rudlin and Falk (2009) described the fringe belt areas as an ill-defined space or as a 'shatter zone' where considerable capacity exists for new development. Yet, it is striking that, generally, fringe belts retain their distinctiveness long after they cease to be at the actual fringe of the city. Although their

character inevitably changes to some extent, they tend to remain distinctive from adjacent areas (Whitehand, 1967).

Management of the Dublin intermediate fringe belt

The Dublin case study, the north intermediate fringe belt, is currently the subject of redevelopment proposals in respect of such key plots as Mountjoy Prison, Mater Hospital and Grangegorman area (previous Richmond lunatic asylum and penitentiary). The current Local Area Plan for the Phibsborough Mountjoy is illustrated in Figure 18 below and from this it is evident that the boundary line of the plan is entirely unrelated to and ignores the actual structure of the fringe belt character.

Figure 18. Phibsborough Mountjoy Local Area Plan and key development sites (Source: Dublin City Council Local Area Plan).

It is, however, worth noting that the essential site character of these fringe belt's plots is being retained. Thus, at least along this stretch of the fringe belt, the overall character is not under threat for the moment. Nevertheless, clear unambiguous recognition of the morphological character and its important historical development would provide an important critical basis for planning policy and mapping a vision that could guarantee for posterity more forthright conservation of the character as an integral part of the development of the area under study. The failure in planning to pay due attention to the urban fringe belt as an entity reflects the fact that decision-making has been almost entirely on a site-by-site basis instead of adopting a holistic view of the urban fabric.

Final Remarks

The town plan study of fringe belts, involving historic and geographical components of a city, reveals clear morphological patterns. For reasons of their cultural importance as well as embodying communal memory, these patterns must be recognized, appreciated and managed as urban historic documents.

Besides the morphological significance of fringe belts, they are worthy of conservation for cultural, scenic, ecological and recreational reasons. Moreover, they have the potential of providing a model for the structuring of urban expansion, mediating between historic and new urban fabric. It also might be noted that this morphological phenomenon can prove particularly

relevant conceptually in spatial planning given the current economic recession and consequent stagnation in urban growth. In other words, the past could well provide a model for the future, but for this to occur the urban fringe belt as a historical form type must be fully appreciated.

New University Complexes as a force of shaping the urban form of the medium sized cities in contemporary Iran, a case study of Najaf Abad

Ario Nasserian¹, Valeriya Klets¹, Sara Kalbasi²

¹ Dipartimento DIAP, DRACO ,Università di Roma "Sapienza", Italy. ² Islamic Azad University of Najaf Abad (IAUN), Iran. E-mails: Ario.nasserian@gmail.com, Valeriya.kles@gmail.com, sara.kalbasi@gmail.com.

Abstract. Aim of this paper is to study the effect of the newly emerged factors in shaping a city in Iran. In recent years, with the huge increase in number of the students and the wave of building of new universities across the country, in many medium-sized cities, the main element forming the city changed drastically to the university complexes and other buildings related to them. In this paper, initially, there would be a short description of growth of the urban tissue in the city which has been used as a case study, together with a description of the influence of its historical background in the development of historical tissue. Then the statistical and demographic study of the city will be carried out in order to show the trend of urbanization in the city. A summary of the results will prove that by building the university a sudden increase in the rate of city's growth and area has been started, also due to the price change in some neighborhoods of the city, this growth is much more than the others. It would be shown that the general number of stories of the city buildings and the area of the housing has also changed to make the buildings more profitable to rent, as a huge renting population is added to the city. In general, the city's face has changed from a traditional working-class residential city, to a so-called dormitory-city.

Key Words: factors of growth, change of the urban tissue, medium towns, accelerated growth, dormitory city

Introduction

Najaf Abad is a city in the center of Iran in Isfahan Province, 25 kilometers to the west of the city of Isfahan, which is the 3rd largest city and traditionally most important cultural center of Iran. (Fig-1) Being this close to a very big City like Isfahan, has made Najaf Abad always being overshadowed during four centuries since its foundation in many ways and not least, the study of its urban issue.

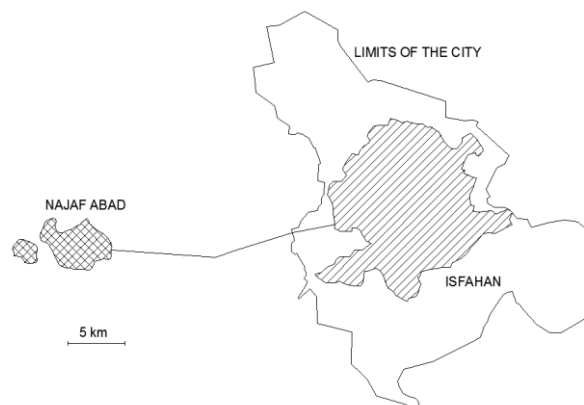

Figure 1. Najaf Abad and its Neighbour, Isfahan

Nevertheless, The urban tissue of this city is a very unique one in Iran, as it is the first city that was built from scratch, as a city and is not outcome of a natural or organic development of a rural area, and the first example of many satellite cities all around Iran, and then a possible role model for many of them. Of many elements affecting the growth and form of a city, one of the most influential ones is the population, as discussed by *Longley et al.(1991)*. The most recent change in population of this city was caused by building a huge branch of IAU (Islamic Azad University) with around 25'000 students which not only changed the city's population as a sheer number, changed the population's desires, needs and requirements and thus changed the lifestyle of at least a portion of the population of the city.

The aim of this Paper is to show the effect of these changes on the urban form of the city of Najaf Abad. The method to do this study would be to investigate the essential urban form parameters in the city in order to attain a better knowledge of the structure of the city, study of its size and population growth, together with the study of the parameters like the city shape in different scales-starting from Macro scale- different densities in different zones, different rate of growth, and finally visiting the city in order to obtain some visual evidences.

Historical Growth and background of city

The city was founded in 1613 by the direct edict of the Safavid court, with some administrative objectives, which the most important one of them was to establish a settlement in the west of the capital to give the region more security and stability. In order to do this and as the city lies in a dry valley, they had to transfer water there. As a very unusual move, it had very unique consequences, and one of these was the very unusual form of the urban issue. As *Bonine(1979)* describes, there are very few variations in the general forms of the city blocks in Iran as they are usually influenced by the same factors everywhere. He suggests that a very influencing factor, particularly in the regions with few water resources is the city's water network shape, specially underground water network (Qanat). In this case as the water had to be brought from somewhere else and the watering network could have been designed in any desired form, it wasn't a factor at all. This effect of water on shaping the city is further emphasized by *Spooner(1974)*.

The fact that due to the lack of water in place there was no rural settlement, plus a flat topography and the Safavid urban preferences was the reason of a very regular plan for the city with a big square which is very characteristic to that period. This center and the general macroform of the city in its three phases of growth are shown in Figure 2.

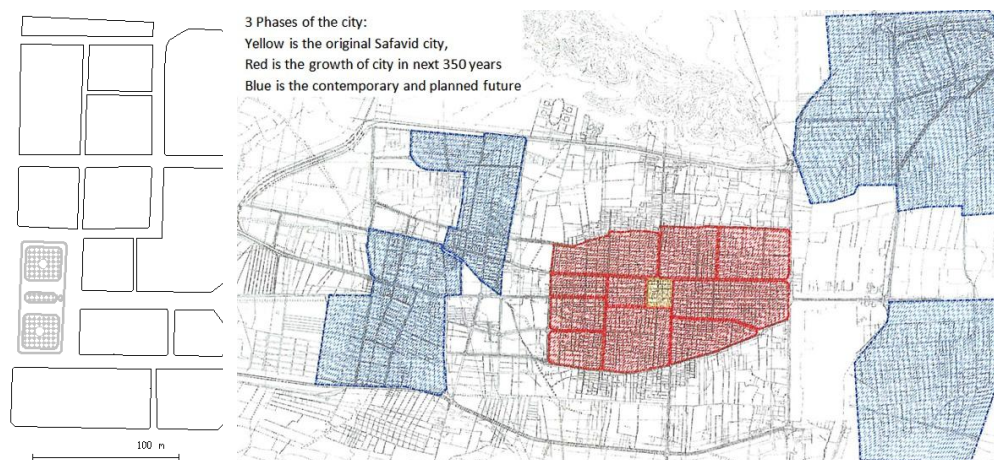

Figure 2. Safavid city center of Najaf Abad, a regular Cartesian tissue and city's development phases.

It is very obvious that this is very different with the usual perception of an Islamic city which is usually described in his way: "irregularity and anarchy seem to be the most striking qualities of Islamic cities", (*de Planho, recited by Bonine, 1979*) or "the organic, irregular plan . . . is universal in the Muslim world, . . . Muslim towns grew so spontaneously and haphazardly as to prevent the development of a systematic street pattern." (*English, recited by Bonine, 1979*). Later the government decided to build the arms factory of the Safavid army there and thus moved the workers and their families there too, therefore increasing the population.

The city has been always in strong and direct relation with its bigger neighbor, Isfahan, If Isfahan was in a prosperous period so prospered Najaf Abad and in the times of decline of Isfahan, it was on the decline too.

In the years after its foundation until the middle of the previous century, Najaf Abad had grown on the basis of an agricultural economy, with a somehow steady and slow growth, at 1950 the process of Industrialization of the region started, causing a rise in the influx of the immigrants to the city and thus making the growth more rapid.

Contemporary Growth of the city

Using the documents provided by the municipality of the city, one can draw the boundaries of the city in the past 60 years, the way it is shown in the (Fig-3). Using the terms given by *Allain (2004)*, in the scale of the Macro form, it can be seen that up to 1983, the city was growing in a single, almost round agglomeration, But the last two phases of city development show significant deviation from a centrally growing city, First, city starts to grow along the north-south road which is its eastern boundary, then new neighborhoods which are not connected to the main body of city appear, and continue growing.

Figure 3. Limits of contemporary Najaf Abad, Growth of the city in last 70 years.

In order to have a good understanding of the city's pattern and rate of growth, it is useful to have a quantitative estimation of its city's population and area growth per year. The Chart shown in Fig-4 represents the city's area by square kilometers in past 70 years and the annual growth rate percentage for the city. It can be seen that with an average annual growth rate of 7.3%, it is growing quite rapidly.

Figure 4. Growth of the city, Total Area by square kilometres.

Here rises an interesting issue, if two later stages of the city growth are considered, it can be seen that in this phases the city is expanding much more in the new neighborhoods, than it is growing by expansion of the initial core areas which are traditionally more pleasant and more expensive areas. In other words, one can reach to the conclusion that for some reason attraction of the new neighborhoods is more than the main core of the city for increasing the urban area. Fig-5 Shows this phenomenon of the satellite area growth.

Figure 5. Growth of the main body of the city and he satellite cities.

In order to understand the process of the growth of the city and the change of its shape better, the main elements shaping the macroform of the city shall be considered, Ghahraei(1996) counts four important factors: 1- the mountain on the north which won't let the city to grow northward further than a certain limit. 2- Gardens and fields which used to surround the city, has been transformed to the city tissue, so the tissue follows the arrangement of the old fields which in turn get their shape from the waterways, this element is close to the origin for shaping process described by *Bonine(1979)*. 3- City's position on a main road connecting two important regions of the country-main oil fields of the Khuzestan to the main industrial pole of Isfahan, has been instrumental in redesigning the city as a linear one -along the axis of the road- in the modern period in Iran, which later changed and took its current form. 4: The General slope of the city site, east to west, and equal to 0.1% which is used for water network system has been an adding influence to the orientation of main streets inside the city.

Also it has to be noted that this rapid rate of growth has made the city unable to form any shape of a fringe-belt or a fixation line (*Conzen, 1960*) with green areas and low population around the city.

Study of the Population of the city

Study of the development of the city would be impossible without study of its population. The data available to writers, states that in 1956 city had a population of 30422, and by the start of 2013 city's population had seen a very sharp increase to 246017, which means during a period of less than 60 years, city's population has increased more than 8 times. Fig-6, shows the total number of inhabitants of the city during this period.

Figure 6. Population of the city

Naturally, this population is not distributed homogenously in the city, Fig-7, shows the density of the population in the city area. In order to make this diagram, a basis of four groups for density is used (*Conzen, 1960*), the limits of these groups are: Low: Less than 5000 inhabitants per square kilometer, Medium: Between 5000 and 10000 inhabitants per square kilometer, High: Between 10000 and 15000 inhabitants per square kilometer, Very High: more than 15000 inhabitants per square kilometer.

Usually one will expect to have the most population in the city center, and to observe a decrease in density by getting away from this center (*Allain, 2004*), but the pattern of population distribution is not this simple. It can be seen that in the old city center, there is an average density, comparing the Fig-7 with Fig-3 shows that the parts with highest densities all belong to the constructions in the past 30 years, (after 1983), it can be also seen that formation of these parts in the main core of the city corresponds to an almost 30% increase of population in early 80's and late 70's (Fig-6). Further development of the main core of the city is in medium density as expected. *Longley et al. (1991)*

Figure 7. Density of Population in City area (2010).

There are some parts of the city center, which due to their old origin-comparing Fig-7 and Fig-2 shows that this low-density part is the same old Safavid part-, were dedicated to some functions which have remained the same (like mosques), these urban elements together with the municipality trying to keep and renovate the city center in its old shape (Fig-8) has been instrumental in keeping the density in city center low.

Figure 8. Renovation of the city center which keeps its density quite low.

New trend of construction in the city

Now having in mind from Fig-5 that more than half of the growth of city in its last two phases of growth belongs to the areas outside of the city core, and considering the Fig-9, one can reach to a conclusion that city's most recent construction is designed for more population density. This goal can be achieved by two means: Smaller homes and/or more stories for the residual buildings.

Figure 9. Percentage of different densities in total city area in different parts of city.

This act can be confirmed by two more observations: First, change of form in residential buildings of the city. In order to understand this change of form, one has to look in to the block plans in different areas inside the city, to have a logical comparison two blocks which almost have the same size and belong to the same population density category have been selected.

Figure 10. Comparison of two neighbourhoods, before(Left) and after(Right) construction of IAUN.

These blocks are shown in Fig-10. There are some clear differences in these two blocks, which can be listed as follows: (1) The houses are shaping in a much more orderly form, more suitable for larger constructions. Also they almost have the same length perpendicular to the streets. (2) Secondary alleys and central courts are eliminated completely. Remembering these alleys are the spaces that form a pseudo-private entrance to the buildings and the concept of center court just applies to a family and private space, these changes are a step toward de-privatization of the residential spaces. (3) While the coverage area of the building is 59% in the old formations, it has very slightly decreased to 57% in more recent buildings.(Note that the municipality regulations in Iran limits this ratio to maximum of 60%).

Also a very significant change is number of the stories of the buildings. Almost all the city has been in one or two stories, less than one percent of the houses had three or more stories. But in the recent years residential buildings of more than three stories are quite common, statistics of the region shows the demand for buildings with more stories is increasing. In Fig-11, percentages of the buildings with various stories built in the year 2011 in the city are shown, together with the under construction buildings in developing parts of city.

Figure 11. Recent buildings, change of trend in the number of stories.

Figure 13. Demolition of the old one story buildings and building multi-story ones.

Conclusion

Demographic and statistical analysis together with study of the urban macroform and medium scale study of the tissue of the city, shows that a change in the population characteristics and the demands inside a city can have significant consequences on the urban tissue of the city. In the case of the city of Najaf Abad, the building of university complexes has been very instrumental in changing the demography of the city's population and hence its demands.

In Najaf Abad, these consequences can be singled out in three ways: First, change in urban macroform, which happens in two ways, stretching toward the university centers and clustering around them. Second, it impacts the general form of tissue, makes it more regular, and usually in bigger land portions for construction and third, the general shift of the buildings toward multi-story buildings to provide more residential space.

Najaf Abad which has long been a satellite city for Isfahan, now is working as a huge dormitory for the university complex near it, which gives it a dual dormitory function, for the city that it is a satellite for and for a satellite cluster of its own. It shows that the size and importance of two settlements is not the only factor deciding their roles towards each other, functions and requirements inside each of them are important as well.

Urban Black Holes: the rural in the urban as liminal spaces from where to build a new city

Abstract. *This paper takes an anthropologically informed approach to urban form and to a particular space and its social world: the so called hortas (vegetable patches) in Porto, Northern Portugal. These hortas are small sections of land located along a water corridor that are cultivated outside any legal frame by local neighbours, thus producing informal grower communities. Since the traditional narrative on city growth is one of the urban form expanding while agricultural practices are relegated to other spatial realms, the 'rural' is not expected to be an element of the 'urban'. As such this paper deals with what could be thought of as 'urban black holes': 'the rural in the urban'. Through an ethnographically informed analysis we argue that these hortas are not mere 'survivals' of past stages of the city's evolution and growth, but an essential element of change in today's city where city dwellers take power into the urban landscape starting a new paradigm of urban community life.*

Key Words: Rural-in-the-city; Liminal-spaces; Informal communities; Water-corridors

Introduction

After thousands of years of urban development we still can find places in some neighbourhoods that look very different from what is commonly understood by 'city'. These other places are frequently located in the internal margins of the urban fabric, and although they display strong roots within the urban structure, they are not necessarily tied to 'the constant grey' of the city. They are frequently seen as an urban emptiness, as urban black holes. But in fact, in some instances connectivity and urban growth have forged a rich urban-life setting. This paper analyses two such places.

The sites are two urban hortas located in the city of Porto, Northern Portugal. The Portuguese word hortas comes from the Latin "hortus", meaning garden, and is used to refer to vegetable plots. The cases under analysis are working-class informal community-related grass-roots hortas, as opposed to City Council or urban middle-class environmental-conscious association sponsored hortas. They occupy areas where the built city has stopped developing, probably due to the water corridors that are one of the main morphological elements of these two sites.

We will first describe the morphology of the hortas and their topographical relation to the surrounding city elements. Because the methodology involved in this study is also anthropologically oriented (thus involving direct contact and retrieval of information with the members of these growers communities), a central role will also be given in this paper to the social world that both produces and is produced by the hortas.

Urban vs Rural

What is a city? Lewis Mumford posed this very question in 1937. His answer was that "[t]he city, in its complete sense,... is a geographic plexus, an economic organization, an institutional process, a theatre of social action, and an aesthetic symbol of collective unity" (Mumford, 2003:94). According to Horta (2011) a settlement is a city when it displays demographic

density, social division of labour, social differentiation, public services and a concentration of the secondary and tertiary economic sectors. The first sector, agriculture, is never referred to as an element constitutive of the city. The European industrial revolution of the 1700s and 1800s, with its major impact on the economy, social organization and life-styles of western cities, is the element that more strongly builds the present-day idea of the city as 'a place of work' (Santos, 2014: 113), even if today that work is mostly related to the service economy and not to industry. Thus, presently, the idea of 'city' does not generally entail agricultural practices (Gottdiener, 2014:19). If any forms of agriculture were to be found in urban contexts, they were seen as 'survivals' of past times, as anachronistic practices that time and the inevitable march of progress would make disappear.

In this paper, and as a result of the fieldwork carried with urban grower communities, we argue for a different perspective on and a different understanding of these agricultural practices in urban contexts.

The two sites

The morphology of places is an essential element in the process of constructing the urban space and its social world. Thus, morphological conditions of urban systems create the possibility of specific situations that support the emergence of specific spaces within the urban system. Liminal spaces are one such type of place. The hortas here under analysis are liminal spaces where the essential interaction between humans and nature (the latter taken in a very broad sense) is enhanced. These liminal areas and their social systems tantamount to other places that are protected and stewarded by the local communities that produce them.

The cases presented here will be named Horta A and Horta B. They were both differently shaped by morphology and history.

Case study 1- Horta A

Horta A (Figure 1) is located on one of the edges of the city (the River Douro) being a natural storm water drainage. The verticality of the place and the steep slope contributed to the overall erosion, mainly due to the continued water run-off, washing the topsoil away. The land is the property of one of the city's universities and the growers make use of it with the approval of the institution. The number of growers that constitutes this community is c 15 people. The total area of the cultivated plots is 20 000 square meters. According to the information collected through fieldwork, cultivation has been taking place on this site for over 15 years.

It is understood that horta A is located on the terrain of a former Quinta (agricultural estate). The old retaining walls of rock and stone appear and disappear on the site. This element helps integrate the new agrarian practices with the old infrastructure in a space that claims to be something new (the horta/growers community) in between the remains of old rural-urban city borders and the contemporary surroundings and community. The community garden plots are located around the old terraces in irregular shapes and at different levels. The remaining elements from the past Quinta help to subdivide the space and make it easy for people to define their own individual agricultural space.

The food grown by this community ranges from potatoes, to beans, tomatoes, onions, lettuces, cabbages, spinaches and, in some cases, strawberries. The water has been collected and centralized on the highest point of the urban stream flow and it is currently one of the main morphological elements of the horta: the grower community decided to build a small water retaining structure for that stream (Figure 2: Site A-Water Pond). The work was carried out by them sharing labor, materials and expenses. From the ensuing pond, water is distributed by dug out canals and pipes to each corner of the horta in order to irrigate people's crops.

Accessibility to the horta is limited with only three points of entry (Figure 1) being very well protected (there are gates with locks for which you need keys). Growers say that the land

belongs to the university and as such they feel responsible for what is going on inside the horta. This is the reason they give to the importance they attach to keeping control of the access to the grounds.

Figure 1. Map of Site A.

Figure 2. Water structures (Site A and Site B).

Case study 2- Horta B

Horta B (Figure 3) is located on a flood plain of a small creek. This type of land formation (ie, flood plains) has been avoided by the development grid of the city due to the unstable ground conditions. The area where this second site is located is an area where the city meets in a multi-scalar way (Figure 3). All the different elements coexist in an extensive open space where the cultivated plots (aggregated in more than one unit) occupy c 68 500 square meters. In this paper we will only be describing a smaller section of the complete area: Horta B, occupying c 19 000 square meters.

Located on a horizontal landscape (the flood plain) there is usually a couple hundred meters or more between the horta and the surrounding elements part of this landscape. Just like in Horta A, rock walls are important elements here that create a unique space and provide a minimal structure for this horta. As a morphological element of the landscape, these walls also provide shade and accentuate the sun's position and thus the temporality of the space.

The small creek that runs through the site brings water from the costal hills (100 m elevation) into a bigger creek that runs through the city all the way to the Douro. The water quality of the creek is extremely poor, being polluted by industrial units located upstream, on the exterior of the ring-road. Using water as the main resource (Figure 2 Site B – Water canal) local people have been growing food produce such as potatoes, beans, tomatoes, onions, lettuce, cabbage, spinach, flowers and some fruit trees. The community of growers of Horta B is constituted by more than 30 individuals (both male and female but, again, with a predominance of the former). They have been cultivating this particular section for more than 12 years. The growers do not know who holds the deeds of the land they are cultivating.

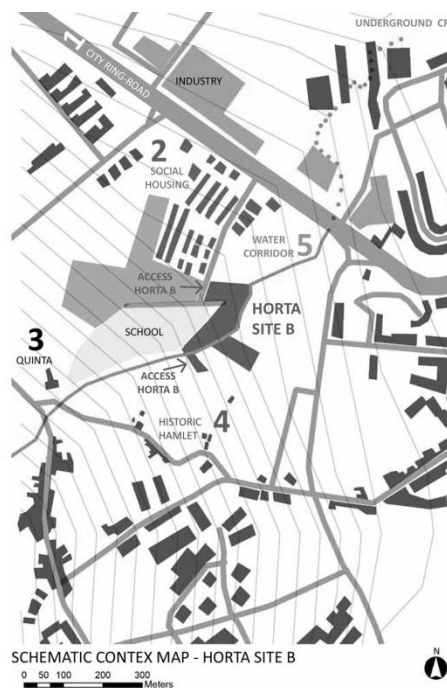

Figure 3. Map of Site B.

Community Space

At both sites the housing community next to the site supports (although not exclusively) the hortas. Some of the growers might live fairly distant from the horta site, but have connections (through family or work) to the first growers of the horta. According to the narratives collected through field work, it is usually the men who take the initiative to start cultivating next to the creek. They also clean and prepare the site for agricultural uses, especially on steep slopes. All the physical activities and the daily chores that these urban agricultural units demand imply a lot of effort and time, but hortas are spoken of by their growers as “doing you good”.

The sense of goodness that growers attribute to the hortas is the main and the most common characteristic in the growers’ discourse. According to them, hortas are keeping people active and consequently healthy and consequently happy. The horta is a source of goodness because it steers men away from the *tasca*, but also because it implies an outdoor, physically active life-style.

The goodness of the horta translates itself also onto the goodness of the food produce grown in them. As the growers say, “the food I buy in the supermarket, god knows where it comes from and what stuff they put on it! This one, I know it is healthier because I grew it myself – and it tastes better too!” So, to the goodness of the activity to one’s health, one adds the

goodness of the produce itself: free from commercial farming practices and associated ‘evils’. An additional goodness of the practice is the contribution it makes to the household economy. However, this element of contribution to the family budget is never presented as the main impetus for the agricultural practices. Growers refer to the reason why they grow food produce mostly because they take pleasure in it, because “it is good for you”.

Besides being inhabited (or having as a morphological element) the openly voiced figure of ‘goodness’, hortas as an urban terrain are also inhabited by (or have as a morphological element) the circularity of ‘the gift’, in the sense Marcel Mauss delineated it in the 1920s. So, what is the object of the gift in the hortas? The most immediately circulated element is the food produce. Growers refer quite often to the pleasure they have in offering some of their produce surplus to family, friends and neighbours. With the economic crisis the country is presently living, this gift of food produce is even more welcome than before. However, none of the growers refers to selling their produce surplus.

The second element that circulates through a gift economy is labour. The pooling of labour is a well-known social feature in agricultural societies. In the hortas, very often growers referred to the fact that if one of the growers is off sick and is not showing up regularly at his/her plot, they will carry out the necessary tasks so as to the crop is not lost. In times of more intensive labour everyone receives help from their neighbour to cultivate their sites.

The third element that circulates through a gift economy is knowledge. According to the narratives collected, some growers have approached the initial growers, not only to ask if they could also cultivate a section of the land (due to the liminal nature of the space in legal terms, they did not know whom to address for such authorization but for those who somehow were already farming the land), but mostly to learn from them how to grow things successfully.

These urban cultivated areas are liminal spaces that are central places to these peoples’ lives. They are places where people interact with the landscape and, most importantly of all, places where they are able to build their own interpersonal space. Elderly people, young women and children have now a space to share their knowledge, to be physically active and where to enjoy leisure time and the beauty of the landscape, of their farmed gardens and of the city.

The hortas as urban black holes

Hortas are liminal but not marginal spaces. They are interactive spaces of exchange in hidden areas inside the urban structure. The hortas are the result of a complex morphology and changing ecosystems. The identity and particular culture of these places are extremely important to the urban dwellers that cultivate them. Local people protect and understand the natural landscape of the area making these places key elements in the urban landscape connecting nature and people.

As far as morphological elements are concerned, on both sites water is the main actor of the natural settlement and responsible for preventing the city from developing the grey in those areas. The cultivation of the landscape requires spreading water in different directions and along terraces. The necessary slowing down, sinking and spreading of water helps both to control the erosion as well as keeping the soil fertile. It also involves the community by implying shared labour and shared water management, as well as giving these city dwellers a place to cultivate.

As Martin Heidegger (1951:2) said, to build is to dwell since “in the word *bauen* we hear three things: 1. Building is really dwelling; 2. Dwelling is the manner in which mortals are on the earth; 3. Building as dwelling unfolds into the building that cultivates growing things and the building that erects buildings... We do not dwell because we have built, but we build and have built because we dwell, that is, because we are dwellers”. The hortas are places of dwelling where exchange of knowledge is constantly happening, where community resilience is produced, where people engage in physical activities and an environmental consciousness develops. The protection of these spaces and their communities is very valuable. The hortas here

presented are a clear example of a social nucleus and a scenario of a unique urban community culture.

The fluidity of time and the challenges that these sites present have taken people to settle in them in a flexible way, away from rigid systems which so often our urban grids produce. It is clearly under the physical/morphological conditions of the place that essential human values are taking root, values that are related to identity and to livelihood and that so often our cities curtail by hiding them among the anxiety and the productivity that the urban promotes. And it is the realization of the latter reality that prompts our questions on our cities of today and their public spaces, on the absence of freedom, flexibility and capacity for transformation that is limiting our ability for harmonious human development.

A lot of our green public spaces, usually named 'parks', are places that promote another type of spatiality not that of the hortas'. In parks there are limited forms of interaction between people that is accompanied by a continuous exhibition of the self to others. Parks as promoters of leisure have forgotten about important human activities of connection between the individual and his/her territory, namely about the incorporation in them of communal activities of subsistence that should be salvaged and protected. The hortas here presented, due to their grass-roots nature are a reflection of the freedom of the human. It is in the hortas, spaces that are usually read as an urban emptiness, that in fact the dynamic exchange between individual and environment takes place. Thus the metaphoric term of 'urban black holes' in the title of this paper.

A black hole in Physics does not in fact refer to an emptiness but to a location of immense energy. The same way, hortas are not an urban emptiness, but spaces in which there is instead a concentration and exchange of energy vital to our survival through time, not as individual beings, but as social communities that belong to a live ecosystem in which we dwell in the Heideggerian sense of the word. And by analysing the hortas as part of Porto urban system, two questions arise: was it the morphology of the place that has promoted those values or were we ourselves who knew not how to build the city under those values? And how does a formal system of territory management embrace an informal system without annihilating it?

Abstract. *Universities have a preponderant role in today's societal models especially under the influence of the knowledge economy. They have been in the core of development — economical, social, inter alia — and their role within urban context has changed in order to respond to the third strand of the university mission — that of civic engagement. Whether conceived as autonomous entities or diffused within the urban fabric, universities are a key element in urban dynamics and policies and they are progressively more included in strategic plans and development actions worldwide. Therefore, it has become significant to understand the extent of university integration within urban territories. This paper aims at exploring an analytical framework for university precincts within urban fabrics, understanding the different types of urban insertion and connections established with local and regional players. The focus is placed on the impact of the university precinct at the level of the adjacent urban fabrics, on an attempt to understand the ways universities can relate to their hosting cities, from a morphological point of view. The University of Bergamo, Italy is used as a case study, for the diversity present in the urban insertion of its physical premises.*

Key Words: University precinct; urban integration; campus; knowledge economy; university morphology

Introduction

This paper focuses on universities and their precincts and the role they perform in urban context. It relies on the premise that universities are a key element in urban dynamics and urban policies and that they have the ability to be powerful urban generators, attracting people and flows, and creating urban vitality (Calder & Greenstein, 2001). Their physical settings act, thus, as the first vehicle through which universities can interact with their hosting city.

Within the context of the knowledge economy, universities are progressively being perceived as one of the most influential elements in society, since they impact on city development on several levels (Wiewel & Perry, 2008). They have the ability to change city demographics, to act as economical developers and to impact on several ways on society in general. Besides, universities can contribute to urban regeneration, by directly improving the quality of the urban fabric, and helping to reclaim parts of cities and leverage funds from public regional players. Therefore, it is urgent to understand the full extent of their impact, and to explore university-city relationships.

This paper aims at analysing these university physical settings, on an attempt to understand their impact on the universities' vicinity, and the ability they have to promote synergies and relationships with their urban surroundings.

In order to better explore these matters, the University of Bergamo, located in the north of Italy was chosen as a case study, for its morphological features and insertion in the urban fabric of its hosting city.

This paper is organized in three parts: the first explores the university general context and the key themes involving university facilities planning. The second explores the morphology of Bergamo recurring to space syntax tools, always focusing on the university and its relationship

to the city. The third summarizes an experiential mapping contrasting the results of these observations with the syntactic analysis performed.

Context

It is argued that universities are one of the driving economic forces in contemporary societies (Duderstadt, 1999; Conceição & Heitor, 1999). Their role is not only related to the production and sharing of knowledge, but has progressively developed towards their social involvement and responsibility. Whether conceived as autonomous entities or diffused within the urban fabric, universities are a key element in urban dynamics and policies and are progressively more included in strategic plans and development actions worldwide, thus providing an opportunity for change and new perspectives towards their role in contemporary societies.

Along with the traditional strands of their mission (research, learning and teaching) a third one, that of civic engagement is becoming significantly more important in today's university (Berglund, 2009). This may have substantial implications for the built environment since it approaches academia and the wider community, from simple actions such as allowing the latter to have access and make use of university facilities, to deep mutual involvement and engagement in several activities. Therefore, besides rethinking university-learning spaces at the architectural design scale, it becomes critical to reassess university facilities in terms of their spatial integration within the urban territory, considering both the metropolitan area scale and the city-university interaction. This interaction should be understood as an inevitable component of university collective life (Campos Calvo-Sotelo, 2010).

The research question is focused on how the university precinct turns out to be integrated in the urban tissue.

Nowadays, universities are required to balance between two trends: while it is considered that when conceived as autonomous entities, universities' facilities cause the isolation of academic communities, highlighting ruptures within the urban fabric and originating unsustainable mobility patterns; one can argue that, on the other hand, when universities' facilities are built within the city core, the preservation of their uniqueness and distinctive features may be easily affected by the surrounding environment thus requiring special consideration.

The "campus" should preserve its necessary distinctiveness (Trani & Holsworth, 2010), but also to be open to the city to foster processes of social and economic integration to the community. It is argued that university precincts can no longer be considered secluded places, where non-academic people feel rejected and not welcomed.

Therefore, this work aims at analysing different integration models and their repercussions, in order to better understand to what extent does campus morphology influence the interactions established between the university and the city.

The activities of the university impact their surroundings and wider communities (Alexander, 1965) to the mutual benefit of both society and academia. Therefore, the university precinct must be perceived in its urban dimension, as physical element that acts as conveyor of information, knowledge and an image of higher education, while assuming an important role in the dynamics established between the university and the city where it is embedded.

It is critical to understand the demands that the university requires the city to fulfil, along with the role that the university can play in order to contribute to urban regeneration, by directly improving the quality of the urban fabric and promoting cohesion of social territories.

Methodology

The analysis was performed combining space syntax tools with in-situ analysis, along with student interviews.

It allowed to perceive the city globally, focusing on urban integration aspects, as well as to deeply understand how the university premises relate to their immediate surroundings, and which role they are able to perform in the urban environment.

Depthmap software (Turner 2004) was used in order to build a topological map (axial map) (Hillier and Hanson, 1984), which performs as a base map, considering the scale of the city under analysis. The axial map description operates as a macro analysis of the urban structure. It allows a representation of information on a plane in topological relationship and with measurable horizontal distances, *i.e.* a metric analysis of the catchment area and an angular segment analysis of global integration (closeness centrality) and global choice (betweenness centrality). At same time it has sufficient geographic reference information to identify the location of each university infrastructure.

Along with the syntactic analysis, *in-situ* observations were made, and an experiential mapping of all the university facilities was developed under the scope of the Smarter Citizens research project *i.e.*, a collaborative project between Harvard GSD and the University of Bergamo aiming at developing alternative urbanization models in order to pursue physical, digital and social innovation.

This experiential mapping consists of an analysis based on direct observations by the university users. It draws on the research on urban design qualities related to walkability pursued by the Active Living Research Program of the Robert Wood Johnson Foundation (Ewing et al., 2006), whose aim is to link the built environment to active living. This study relies on the premise that urban design qualities depend on physical features but are distinct from them, and they reflect the general way in which people perceive and interact with the surrounding environment (Smarter Citizens Research Team, 2014a). Therefore, factors as the morphological features and the urban design quality, along with individual reactions influence and affect the way an individual feels about the physical environment. Even though the study focuses on walkability conditions, it allows inferring for other uses of public space, measuring how some physical features of the built environment affect the users behaviours.

In this analysis, five variables assumed to be critical to establish a good walking environment were measured, in order to provide a broad perspective on the areas surrounding the University locations in Bergamo: imageability, enclosure, human scale, transparency and complexity (Smarter Citizens Research Team, 2014a). A 5-minute walking distance was considered, according to the city's morphology and the walking culture of the students and city dwellers.

Bergamo and the University

Bergamo exemplifies a typical mid-sized European city, with its 120.000 inhabitants (approximately 500.000 in its surrounding area). It was developed from upper town (*Città Alta*), an urban settlement located on top of the hill, which is surrounded by Venetian walls dating from the 16th century. *Città Bassa*, downtown, was developed mostly from the second half of the 19th century, after the construction of the railway and train station, located in the southern part of the city (Comune di Bergamo, 2008). *Città Bassa* was developed through the existent *borghi*, the smaller urban settlements adjacent to the upper town, although located outside its walls. These areas vary in type, number of inhabitants and architectural styles, and they represent a part of Italian urban culture (Comune di Bergamo, 2011).

Figure 1. Bergamo urban mapping (Smarter Citizens Research Team, 2014b) (1) Città Alta . uptown; (2) Città Bassa – downtown.

The University, *Università degli Studi di Bergamo*, dates back to 1961, even though it only achieved university status by the end of the 1960s. Nowadays it hosts approximately 15.000 students, among its six departments (*Università degli Studi di Bergamo*, 2013b).

The university is spread within the city in several different locations, both in *Città Alta* and *Città Bassa*, and also in the outskirts (*Università degli Studi di Bergamo*, 2013a). Different locations host different areas of study, for the four main locations of the university. Thus, all the locations within *Città Alta* are dedicated to the Humanities, while in *Città Bassa* is located the Economy department. Finally, the Engineering department is located in Dalmine, a smaller city situated about 10km from Bergamo. The university is also a partner of *Kilometro Rosso*, the technological park, owning one of its buildings. In this facility, most of the areas are only used for research but some of the spaces are available for specific purposes, even though there are no regularly scheduled academic activities.

In the upper town, the university occupies 7 different locations, spread around the main areas of the centre. Most of these host academic spaces within. Students travel around to attend classes, which can be seen as an opportunity or a threat. On the one hand it allows for more dynamism within the area, caused by students presence in different places during the day, but on the other hand requires more resources and can provide distractions from the academic environment.

In *Città Bassa*, the university location hosts more functions and provides more services, thus being used not only by the students who attend classes there, unlike what happens in *Città Alta*.

Both the university premises in *Kilometro Rosso* and the Engineering campus in Dalmine, are not going to be considered in the framework of this paper, since only university premises located within the city's boundaries and hosting academic areas were considered.

The dispersion of the University is a defining feature for Bergamo, and can be perceived both as an attractor and as a negative feature while characterizing the university. On the one hand, the dispersion allows the university to reach more areas of the city, and to interact with different environments. On the other hand, the university is not perceived globally, and it does not become clear to both city users and students themselves what is the role the university is

playing in urban context. Its premises are unknown and disconnected, even though located in some of the most central and important areas of the city.

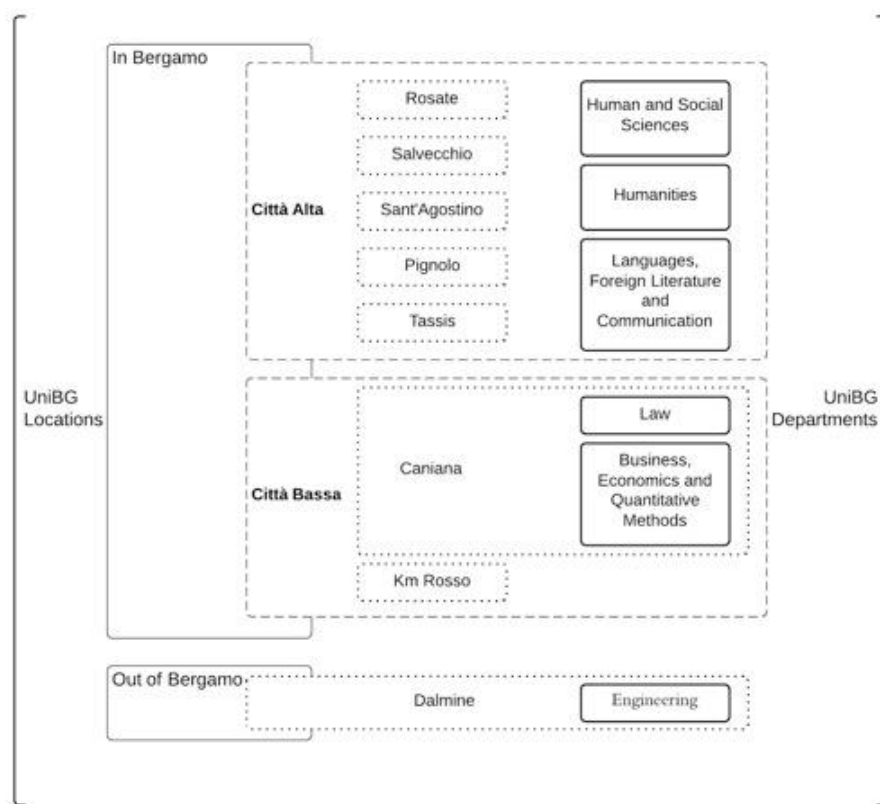

Figure 2. University of Bergamo spatial distribution and organizational structure.

Figure 3. University locations in Bergamo (1) Città Alta, (2) Caniana – Città Alta; (3) Kilometro Rosso – Città Bassa.

Axial analysis

The city fabric shows strong morphological differences between *Città Alta* and *Città Bassa*, which can be easily recognised in the axial map. As can be observed in the picture, the upper town shows relatively low values for integration, which are consistent with the perception of the territory obtained through the empirical observations. One of the justifications for this fact might be the topography of the area, mountainous and steeper on the northern side of the hill where *Città Alta* is located, opposed to the flat land in which *Città Bassa* was developed through the *borghi*.

Figure 4. Integration HH Bergamo, with the university locations.

Nevertheless, *Città Alta* presents a historically and culturally rich environment, very propitious for the location of an academic institution. The area's lack of integration is resolved through the use of cable cars, which increased global integration of the whole system by approximately 25%. However, this increase only affects pedestrian accessibility.

In *Città Bassa*, however, the university's premises are located in one of the most integrated axis of the city and are easily reached by any other street in the urban system.

Experiential Mapping

The experiential mapping consists of an analysis built on direct observations by a group of 13 students from University of Bergamo involved in the Smarter Citizens research project. This group includes students with different backgrounds and from different areas of study,

This experiential mapping analysis was based on the research on urban design qualities related to walkability pursued by the Active Living Research Program of the Robert Wood Johnson Foundation (Ewing et al., 2006), whose aim is to link the built environment to active living. The analysis does not focus specifically on the university buildings, but instead on the

whole area on a 5-minute walking distance from them. This approach allows a better understanding of the integration and the morphological features of the surrounding environment of the university. It allows also recognising some aspects of the university's urban insertion and connections. A scale from 0 to 2 was used to quantify all of the variables, 0 being the lowest level, and 2 the highest (Smarter Citizens Research Team, 2014a). Thus, the university facilities and locations with academic functions were evaluated for the above-mentioned criteria: (1) Imageability – as the quality that makes a space memorable and recognizable (Lynch, 1960), depending on how the physical elements and their arrangement are able to draw attention, arouse feelings and create a lasting impression; (2) Enclosure – the degree to which the public space is visually defined by vertical elements (Cullen, 1961), such as buildings, trees, walls, among other elements; (3) Human scale – referring to elements that are perceptible to humans while walking in a specific area (Ewing et al., 2006). These can be materialized in different textures and elements, but matching human size and scale, as well as rhythm and speed of dislocations and movements; (4) Transparency - the degree to which people can see or perceive objects and activities beyond the edge of a street; (5) Complexity – the visual richness of a place (Apopod, 1990 apud Ewing et al., 2006). A place complexity depends on the variety of elements and articulations present on the physical environment.

For the university locations in *Città Alta*, the 5 premises with academic functions were analysed, and the result is summarized in the picture and table below.

Figure 5. Locations of the experiential mapping – Città Alta (1) Rosate; (2) Salvecchio; (3) Sant'Agostino; (4) Pignolo; (5) Tassis.

Table 1. Experiential mapping summary - Città Alta

Criteria /Location	Imageability	Enclosure	Human Scale	Transparency	Complexity	Total Score
Rosate	1	1	1	1	2	6
Salvecchio	1	2	2	1	2	8
Sant'Agostino	2	0	1	2	2	7
Pignolo	0	1	2	1	1	5
Tassis	1	2	1	0	1	5
Average <i>Città Alta</i>	1,2	1,2	1,4	1	1,6	6,4

As can be perceived from the axial map, the majority of university facilities are not located in highly integrated areas. Within the limits of the upper town, though, because of the small scale and proximity among the facilities, this fact would not be problematic, if the university was able to make up for the lack of integration with other strategies, such as improving its visibility and imageability within the public realm.

From the experiential mapping, we can perceive the importance that is attributed to features such as the complexity and the human scale of the urban environment, which is consistent with

the urban fabric and the historical morphological characteristics of the area. Nevertheless, the imageability evaluation of the university shows, in general, low values which seems paradoxal. A possible explanation would be the visual richness of the whole area, which creates difficulty in the recognition of each individual building. Moreover, this evaluation is dependent on the students' perception. It is relevant to mention that none of the students who engaged in the project comes from architecture or any related field of studies.

Also, if compared to similar analysis in different cities, it might show different results, since the whole city performs very well for most of the chosen variables.

As far as *Città Bassa* is concerned, the university presents a different type of physical setting, behaving as a campus-like structure within the urban fabric. It doesn't consist of isolated dispersed buildings like in *Città Alta*. It is a clearly defined precinct, comprising two different buildings. Thus, for the experiential mapping, in order to enrich the analysis, four locations around the campus were chosen: (1) Caniana, as the main entrance and more representative informal meeting space around campus; (2) Lower San Bernardino, the area where most shops and services are located, therefore extremely used by students; (3) Upper San Bernardino, where the library is located, and also restaurants, cafes and bars, making it a highly frequented area; (4) Moroni, the area around the secondary campus entrance, which, in comparison to the other three described areas, is less used and visible from the premises and hosts less services and commercial activities.

Figure 6. Locations of the experiential mapping – Città Bassa (1) Caniana; (2) Lower San Bernardino; (3) Upper San Bernardino; (4) Moroni.

Table 5. Experiential mapping summary - Città Bassa

Criteria /Location	Imageability	Enclosure	Human Scale	Transparency	Complexity	Total Score
Caniana	2	0	2	2	1	7
Lower San Bernardino	1	0	1	2	1	5
Upper San Bernardino	1	2	1	0	2	6
Moroni	0	1	0	1	0	2
Average	1,0	0,8	1,0	1,3	1,0	5,0

Globally, these locations show lower values in all the attributes, even though they are more integrated than all the university locations in *Città Alta*.

The principles of the educational campus (Campos Calvo-Sotelo, 2009), establish a comprehensive framework of analysis for university precincts. Analyzing the University of Bergamo under this scope, it becomes clear that some of the traditional physical features are not present, or do not assume the necessary importance. As far as utopia, integral planning and spatial harmony are concerned, the university does not follow the principles, for most of its facilities occupy previously existing buildings. Nevertheless, it would be possible to solve this lack of spatial harmony, if there was a coherent unifying strategy among all of the university premises.

The learning community is not sufficiently encouraged, and the dispersion of the facilities works in a negative way towards this objective. Also the affective and intellectual embracement is not attained through the physical premises, diminishing the impact of the university physical settings on obtaining a strong learning community. The university also needs to improve the morphological features with impact on its visibility and legibility.

Regarding the incorporation of nature and art within the university premises, there is sufficient offer within *Città Alta*, and the university users are able to benefit from it, despite the lack of integration and connections between university and city. Besides, the rich cultural and historical settings present a stimulating learning environment, while represent and enhance the city's and the university's collective memory. Notwithstanding, in *Città Bassa* there is a lack of both artistic and natural landscapes, and the university premises are not fulfilling this need.

Conclusions

The combination of space syntax tools with direct observations has proven a suitable method for analysing university-city relationships, for it allows understanding simultaneously the impact of integration, morphological features and university dynamism on the creation and improvement of synergies between the two entities.

Bergamo presents a very peculiar university environment, with its diversity in morphologies, insertion types, connections, urban fabrics and relationships established between different entities. Nevertheless, the relation between the university and the city should be improved, reinforcing the presence of university users within the social and urban context. A more synergetic environment would be valuable to foster innovation and improve the knowledge creation, sharing and acquisition.

The dispersion of the buildings and locations of the university of Bergamo can be perceived either as a threat or as an opportunity. On the one hand, it can cause the dispersion of the academic community, decreasing the serendipity and the amount of interaction opportunities and chance encounters on an interdepartmental basis. Also, it creates impractical mobility patterns and raises management difficulties. Nevertheless, the need for the academic community to access different locations and premises could help creating positive flows of movement that would benefit the whole city, as long as there were better connections and attractor areas among different university premises, for “(...) *the learning campus is one that maximizes the probability of chance encounters, and encourages lingering once an encounter - whether by chance or by plan - takes place*”(Kenney et al., 2005, p.39). Considering that, in the case of Bergamo, the whole city is the campus, success may rely in the creation of attractors among the different university locations for “*the true success for a city or town lies in the creation and maintenance of a network of spaces that support a variety of uses and users*”(Space Syntax, 2006, p.4). Thus, the scattered facilities offer opportunities for better integration and creation of synergies between the university and the city as long as there is the necessary will to do it.

Acknowledgments

This paper was carried out on the framework of the author's PhD research, funded by FCT – Fundação para a Ciência e a Tecnologia. We would like to thank the whole Smarter Citizens Research Team for their cooperation and contributions, specially Katia Passera, from the University of Bergamo and the students who engaged in the One Univer[city] project, namely Egle Carobbio and Stefano Terranova.

Aging as an agent of change in the way how we occupy our territory

Abstract *The aging of population characterizes the contemporary societies and promotes changes in the way how we are occupying our territory. Today, Portugal stands as one of the most aged countries in Europe with an aging index of 127,8%¹³⁰ - which means that for every 100 young people (0 to 14 years old) there are 127.8 citizens with 65 or more years old. In parallel, there is a marked imbalance in the occupation of our territory: with a high concentration of population in coastal regions (especially in the metropolitan areas of Lisbon and Oporto) and depopulation in the inner - characterized by an elderly resident population. In the inner regions, begins to be frequent to find a numerous unoccupied houses, or even entire abandoned towns. This fact can be seen as an opportunity and not just as a problem. We propose to analyze the potential that these territories may provide in the implementation of resident systems dedicated to the needs of the elderly people, like Home-Villages, and the way of these kind of structures can contribute to the revitalization of depopulation territories; concealed with other structures (a motor for local development) which can potentiated the fixation of young people and promote a intergeracional territory. Through a case study, that summarizes a proposal for intervention, structured in a review of the territory, which aims to revitalize the Pessegueiro town, in Alcútem (Portugal) - unpopulated, with a significant unoccupied housing structure and with an aging resident population.*

Key Words: assisted living, territory revitalization, home-villages, spatial equity, living in old age.

Introduction

Portugal is one of the most ageing countries in Europe. According to data released by PORDATA - referring to the year of 2012 - we know that about 10.5 million inhabitants, less than 15% are young people¹ and over 19% are elderly². If we compare the data on the elderly population, released by the National Institute of Statistics - INE, it is clear that in 1990, there were about 68 elderly people per 100 youngsters, in 2000 that number was higher than 102 and in 2011 increased to over 127 elderly. Current projections indicate that by 2050 the ratio should be of 243 elderly people per 100 youngsters; however the worst-case scenarios indicate that this ratio could reach 398 elderly people per 100 youngsters.

There is a double aging situation affecting the Portuguese population, characterized by the increasing number of elderly people and the decline in births. Between 1981 and 2012 there was a decrease of approximately 41% of births and an increase of over 78 % of the number of elderly (Tables 01 and 02). These figures tend to escalate, the latest projections of INE, indicate that between 2000 and 2050 there should be a decrease of 5% to 58% of the young population, and simultaneously an increased between 63.2% and 76.5% of the elderly population.

¹³⁰ PORDATA – Aging indicators according with 2011 Censos in Portugal., <http://www.pordata.pt/Portugal/Indicadores+de+envelhecimento+segundo+os+censos-525>, Survey conducted in December 2013.

c	1978	1981	1991	2001	2011	2012
213,895	180,690	152,071	116,299	112,774	96,856	89,841

Table 2. Total of elderly population in Portugal (1980-2012). Source: PORDATA

1960	1978	1980	1990	2001	2011	2012
-----	-----	132,638	1.372,543	1.705,274	1.992,034	2.020,126

Another factor characterizing the Portuguese population is related to its distribution in the territory. The 2011 Census revealed a high concentration of population in metropolitan areas (Lisbon and Porto) and depopulated rural areas, with low percentage of young people and high percentage of elderly people.

Against this backdrop, there is the need to find solutions in order to minimize the depopulation of rural areas, where demographic ageing is presented as an agent that characterizes the occupation of territory.

Case study: Monte do Pessegueiro

Approach

We present an intervention proposal in the territory - within architecture and project – for the revitalization of Monte do Pessegueiro³ by implementing infrastructure for the elderly population, similar to the Retirement Villages concept.

Retirement Villages seek to oppose the isolation of elderly people and promote a sense of community life. Integrating housing with trade, health services, household and personal care. In view of this optimization model and aiming to revitalize depopulated areas, the Retirement Villages may, also, come to include units for local development, in such a way to generate jobs and the consequent establishment of young people.

The decision to choose this village focused on the analysis of specific factors: According to the 2011 Census, Alcoutim was the municipality to registered the highest population loss (22.6%); About 44 % of the population is elderly; It has a significant number of unoccupied housing; Presents distinguishing characteristics in the territory, on a local and regional scale; Topographical conditions are favourable for the adaptation of the territory to the mobility needs of the elderly; There are small local industries, handicrafts and agricultural potential, which if expanded may generate employment; •It is nearby villages, that are also, facing a depopulation process (some already completely depopulated). This situation may enable the implementation of a housing "network" for the elderly - and thus promote greater use of the necessary infrastructures for its functioning.

The proposed intervention was established according to five elements of analysis: territory occupation; characterization of the population and housing; enhancing and restrictive factors for the revitalization of the territory. The occupation of the territory exposes local features and links with the region. The characterization of the population is based on data from the INE and Câmara Municipal de Alcoutim [Town Hall of Alcoutim]. The characterization of housing was established through fieldwork held in July 2013, and through the characterization present on reference works on local architecture, such as: *Arquitectura Popular em Portugal* [Popular Architecture in Portugal] [Sindicato Nacional dos Arquitectos – AA (1ª ed. 1961) National Architects Union - AA (1st ed.1961)] or *Arquitectura no Algarve* [Architecture in the Algarve] [Comissão para a Coordenação e Desenvolvimento Regional do Algarve (2005) - Algarve Regional Coordination and Development Commission (2005)]. The identification of enhancing and restrictive factors deems the existence or necessity for the implementation of equipment or

enhancing structural elements for development and the identification of elements that may be restrictive for its dynamics.

Figure 1. Pessegueiro, Alcoutim.

Territory Occupation

For the Algarve region, Orlando Ribeiro (1991) identifies two periods of territory occupation: an old one that resulted into clustered housing; and a modern one, that resulted into detached buildings. Alcoutim still bears the mark of the first period. Pessegueiro, maintains regional population cluster characteristics: a group of clustered houses, with access directly from the street – which arise organic and spontaneously, according to the land's topography.

The resident population is, mostly engaged to agriculture and livestock for subsistence that marks the territory: the presence of fields reaching the limit of clustered housing and small buildings, next to the houses, destined for animals or tools and agricultural products storage.

Resident population

Alcoutim has registered the greatest population lost in Portugal over the last decade. At the time of the 2011 Census there were 2,917 individuals residing in Alcoutim – along 576.57 km² - in five parishes, formed by the 106 population centres referred to as "montes [mountains]"⁴. Pessegueiros is inserted in the parish with the highest number of residents and approximately 40% of its population is elderly (Table 1). Martim Longo recorded, in the last 20 years, a significant loss of population: in 2011 1,030 individuals lived here, this represents a decrease of 25.6% compared to 2001 and a decrease of 35.1% compared to 1991 (Tables 3, 4 and 5).

Table 3. Resident population, population with 65 or more years and accommodation in Alcoutim - 2011 Census INE (ed), *op.cit*, tabela Censos 2011_Idosos_FREG.

Designation	Resident population	Resident population with 65 or more years old	Total of individual s who live alone or with individual s with 65 or more	Total accommodation	Total of accommodation only with individuals with 65 or more years	Total of accommodation with just one person aged 65 or more years

Housing Structure

In Pessegueiro you can find presences of the Algarve vernacular architecture, characterized by rectangular plans, ground level houses – scalable architecture, i.e., prepared to undergo successive enlargements, according to the needs of the household, without introducing façade changes⁵ - the buildings are made of schist masonry (exposed or whitewashed). Schist is also used to line the interior and exterior floors. The access openings are mostly of wood and in existent windows there is often the presence of exterior wooden shutters. The single or double sloped roofs, of lime mortar tiles, cane thatched, connected together and to the elements of the roof structure, commonly referred to as "encaniçado"⁶.

Enhancing Factors

Alcoutim is an aged village and its housing structures abandoned. The revitalization of the territory can only happen with the presence of young people. Thus, it is necessary to promote economic development to maximize the improvement of quality of life of its residents. The introduction of housing structures for the elderly is presented as a potential enhancing factor, that should be interrelated with other infrastructure.

Enhancing factors for the economic development of Pessegueiro: The “Campo Experimental de Opuntias”⁷ bakehouse – plants for a multiplicity of uses, profiteering fruits, ironwork, gastronomy, or firebreaks for forest conservation; the dam besides being used for irrigation may promote structures for water sports, construction of a river beach or natural swimming pools, for the benefit of local residents and as a way to attract tourists.

The interrelation between Pessegueiro's and the surrounding villages infrastructure's could generate the revitalization of the area through actions such as: restoration of cultural heritage to promote housing for elderly and intergenerational; renovation of the road system: requalification of pedestrian passages and road routes; parking areas, resting areas; implementation of qualified and differentiated equipments and services for the elderly; implementation of services and trade (banks, post office, tourism office, trade of crafts and local gastronomy); development of small industries, related to regional products (development of existing industries, crafts and gastronomy; planting, harvesting and processing banyan); establishment of young people (job creation, tax benefits, family support, schools, sports and social assistance); generate economic and tourism development (inn/guest house; river beach, natural swimming pools, rural tourism, senior tourism).

Table 6. Monte do Pessegueiro.

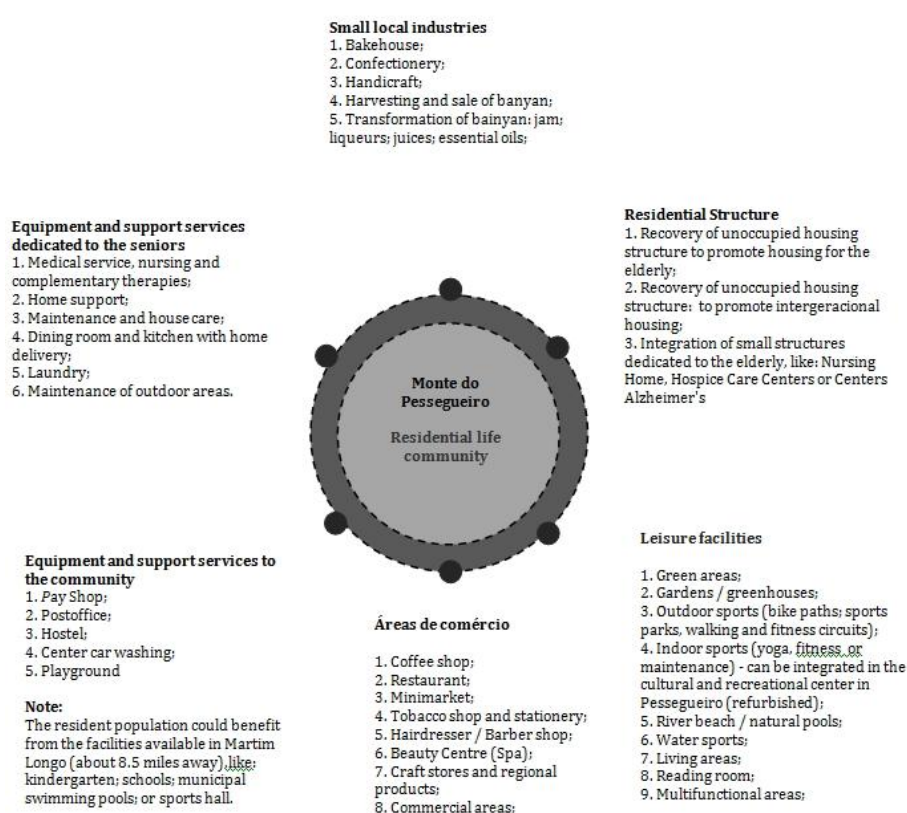

Table 6 presents examples of possible structures that could be introduced in the implementation of a Retirement Village in Pessegueiro, as a community of housing structures dedicated for elderly and, simultaneously, promoting the community's revitalization.

Similar actions where, for example, implemented in Luberon (French Provence), despite gathering different urban characteristics from Alcoutim, presents similar problems, i.e.: aging and isolation of it's population; (e)migraton of young people and consequent low birth rates; lack of commercial, business and service activities; lack of job opportunities; unoccupied architectural heritage; lack of social and economic development perspectives; significant decrease of local taxes' collection; degraded infrastructure. In this region, after analyzing the identified problems, 77 small villages and towns assembled and promoted the revitalization of the area, established by exploiting the economic potential offered by the region and

implementing small measures to improve the quality of life of the elderly population – turned into intergenerational measures, which served as a lever for the establishment of young people with consequent economic development. Joining efforts led to the revitalization of the territory, this situation could be applied in Alcoutim, for it faces similar problems.

Authors like Schittch (2007), Huber (2008), Cisneros (2012) classify housing for elderly as one of the main challenges for architecture and territory planning. However, another challenge in designing structures is preventing them to become "ghettos", even if the same should be enjoyable in regards to architectural space quality. I.e., enclosed spaces, dedicated to people whose only common reference is age. Following this concern, Burton, Bosman (2010) and Steinfeld (2013) warned about the risks of segregation that some of these structures, however well-intentioned, may produce. They also assert that most people prefer to age in places where they can establish a close relationship with the concept home, a part from the image of institutionalization. They further state that, smaller structures - based on the principles of community life and the principles of universal design - may be more attractive both to residents as to the purpose of attracting new residents, of varying ages.

Restrictive Factors

Pessegueiro indicts isolation if compared to close urban centres: Faro and Vila Real de Santo António, probably one of the main factors that has contributed to its depopulation. This implies, for example, the distance to central hospitals exceeds one hour.

Isolation may be presented as a restrictive factor for revitalization. However, there may be other, demographic, social, cultural or economic factors, as well as issues related to the right of ownership of unoccupied housing. It would be necessary to, in line, implement further measures including: development of existing industries and implementation of new units, promoting employment; tourism units; sports and cultural development; agricultural development; creating tax benefits for companies and residents; creation of a social support network to cut across age differences and the needs of the population - Table 7.

Table 7. Proximity relations between Pessegueiro and next reference localities

	Distance ⁽¹⁾	Time ⁽²⁾
Martim Longo	8,5	10 min
Alcoutim	38	45 min
Faro	69	01h : 45min
Vila Real de Santo António	64	01h: 10 min
Ayamonte (Spain)	65	01h: 10 min
Almodôvar	41	01 h
Beja	93	01h: 45 min

(1) Approximate distance in Km

(2) Mean time to perform the calculated route - distance traveled by car.

Land Surveying - data analysis

According to the Municipal Master Plan of Alcoutim - PDMA, Pessegueiro enters into urban land area, endowed with the possibility of building construction intended for "housing, trade or services and installation of public or private equipments"⁸. That is to say that, it meets urban conditions for the elderly housing structure installation.

We have identified 33 unoccupied housing, organized in a street continuous alignment. The majority is badly preserved, for being closed for some time; only a small percentage is well

maintained. This may indicate that with time we may lose part of the architectural heritage (unique and assembled) - Table 8.

Table 8. Conservation Stage of vacant houses in Pessegueiro – survey in 07.2013

	Units	Percentage
Good	2	6,0%
Reasonable	8	24,2%
Bad	16	48,5%
Ruin	7	21,3%

As regards to the outside walls building system, most of them maintain the traditional exposed schist masonry, whitewashed or the combination of these two finishes. Occasionally we verify recent changes, construction changes, with the introduction of painted brick masonry or lined with ceramic materials, or even, coated ceramics, or construction of an additional floor – Table 9.

Table 9. Characterization of exterior walls finishing systems – survey in 07.2013

	Units	Percentage
Exterior walls in exposed slate masonry	8	24,2%
Exterior walls in traditional whitewash finishing	12	36,4 %
Combination with above to finishing	12	36,4%
Others	1	3%

Another feature of the region is the absence of windows, which is verified in 28 of the 33 referenced houses, when there is window aperture, it is most likely to maintain the original wooden frames - Table 10. As regards to doorways, most of them are original, made of wood with one layer and small sized - with a width varying between 75 and 80 centimetres and height between 1.75 and 1.85 metres - Table 11.

Table 10. Characterization of windows – survey in 07.2013

	Units	Percentage
wooden frames (original)	4	12,1 %
wooden frames (original) and other (aluminum)	1	3,1 %
Without windows	28	84,8%
Other	0	0%

Table 11. Characterization of access door – survey in 07.2013

	Units	Percentage
Original in wood	25	75,8 %
Replaced in wood	2	6 %
Aluminum	2	6%
Iron	3	9,1%
Without access door	1	3,1%

The need to provide large spaces - to promote the versatility of space - presents itself as a major factor in housing restoration and adaptation. If we consider the gross construction area identified we verify that most of those houses have a reduced floor area; thereby, we must consider to combine to units for the construction of a single unit with suitable dimensions and space - Table 12.

Table 12. Characterization of gross Building area (Approximate values) – survey 07.2013

	Units	Percentage
Less than 50m ²	12	36,4 %
Between 50m ² and 75m ²	15	45,5 %
Between 75m ² and 100m ²	4	12,1%
More than 100m ²	2	6 %

Twenty houses have terraces (to the rear; along the common main entrance to different houses, or both). We identified three sites with three or more unoccupied houses that share a common outdoor terrace area, which may allow the creation of residence and community areas (Figure 2).

Figure 1. Pessegueiro, Martim Longo – Alcoutim, Unoccupied houses – Survey in 07.2013. Scale 1:2.000.

Figure 2. Pessegueiro, Martim Longo – Alcoutim. Unoccupied houses. Photographic survey in 07.2013.

Synthesis

We can conclude that, from the referenced houses, the majority maintains features of local architecture, but are badly preserved and require significant intervention. However, it is possible to follow their structural and constructive nature and simultaneously endow the space with the desired versatility. Building elements such as walls, roofing and interspaces can be restored and integrated within the new habitability concept. The ratio between street and housing in some cases may require an intervention to remove existing barriers.

Proposal

To promote the revitalization of the territory by implementing a housing structure of community life - based on the structural principles of the Retirement Villages - which can simultaneously promote the restoration of unoccupied cultural heritage, and its adaptability to mobility needs, we hereby present an intervention proposal.

This proposal was formalized in a summarized form in a previous study and synthesizes the exposed concepts.

Image presents the different functional spaces and their interrelations. It is visible the importance of vegetable gardens in the structure of the village, since they are considered as very important for the local population - essential for the maintenance of physical activity and healthy eating (affordable). Support spaces for the resident elderly population – medical and nursing services, maintenance services, meals - were located centrally.

Image identifies new construction proposals, as well as some buildings the use of which may be altered or reclassified. Parking spaces should be considered, organized and allowing easy access to the houses, services, trade and industries.

The fact that the village is "torn" by the National Highway may be a concern to the pedestrian level crossing, since residents of the West side (higher concentration of population) have to cross this road in order to access different services.

The urban structure of Pessegueiro is characterized by the absence of pavement, and should remain so, because this feature undo's the gaps (architectural barriers) – occasionally verified, at the entrance of some houses, a situation that can easily be reversed. The streets may maintain, or restore, regional features with schist flooring, as long as prevention of the danger of falling is ensured (without variations in heights between stones and slip-resistant finish). The arid aspect of outdoor spaces can be minimized by introducing small notes of green spaces, residence and community areas for residents.

The proposed interventions adhere to the principles set by the Universal Design and space use concerns - some of which are reflected in national legislation. Among these, we can list: elimination of physical barriers, such as stairs; placement of switches at a height of 90cm maximum of 120cm; placement of sockets to a minimum height of 45cm; Proper sizing of the spaces to allow its versatility (possible changes in furniture arrangement); allow visual contact with the outside, at the level of the individual when sitting (between 80 and 120cm minimum height from the floor); Use of devices with correct ergonomic dimensions suitable for use by all individuals (doorknobs, taps, supports, etc.); and good placement of equipment in order to enable its use without additional effort (such as dishwashers, washing machines, furnaces, etc.).⁹

Case scenario A presents a small housing, with an approximate gross construction area about 43,00m², badly preserved, inserted in an inhabited building, near one of the community ovens. Given its dimensions, it could only be used as a Studio, one bedroom (double or single), a bathroom and a small private outdoor terrace covered or not. Constructed with exposed schist masonry, precisely whitewashed near the access opening. This house is characterized by the absence of windows, only a small wicket envisages a mark on the facade. The access openings (main and rear facade) do not satisfy the minimum dimensions (height and width) considered as necessary and comfortable, in a living space that respects the principles of universal design, therefore needs to be resized. It is also necessary to regularize both the ground floor level with the interior floor, so as to eliminate any architectural barriers. Another important element for the construction of a comfortable and cosy living space is the introduction of natural light. This can be achieved through the introduction of glass doors with wooden frames (at the access openings), duly protected with wooden shutters – characteristic that respect the design and constructive system of the original door – in order not to change the architectural characteristics of the houses.

Case scenario B presents a set of two houses, also very small (with gross areas inferior to 50m²), interconnected to shape a one bedroom house. This house enjoys two outdoor terraces: one private, at the rear, and the other one is common area, along the main access, marked with shading elements and residence areas. This case scenario includes the interventions mentioned for the case scenario A, especially with regards to the dimensions of the access openings; removing steps at ground floor level; levelling interior floors; provide the rooms with natural lighting; creating wide and adaptable spaces to the various needs of its users.

Conclusion

The depopulation and aging of the rural regions of Portugal is not a modern problem, in a territory marked by inland regions and rural environment. Different rural areas watched their youngsters (e)migrate; schools, health centres, courts, public and private services and local trade closing, generating lack of opportunities; consequently more people abandoned those rural areas.

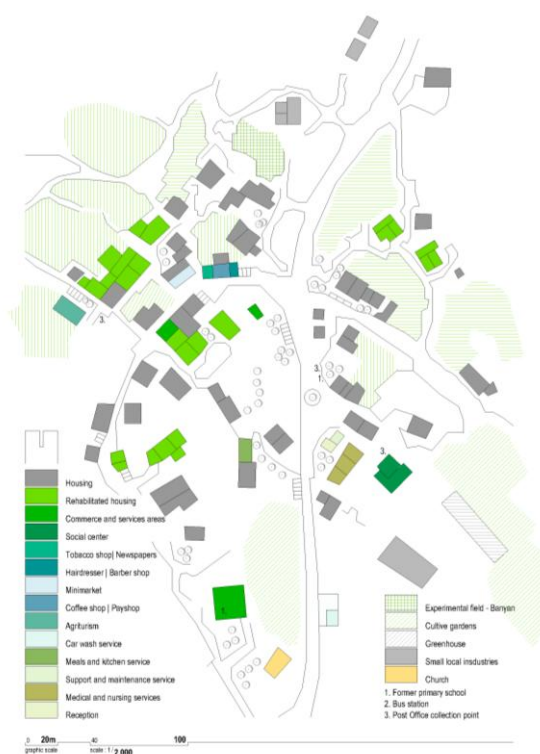

Figure 3. P essegueiro, Martim Longo – Alcoutim. Intervention in the territory: Urban Structure. Scale 1:2.000.

Figure 4. P essegueiro, Martim Longo – Alcoutim. Intervention in the territory: Urban Structure – identification of new constructions, new uses and redevelopment of the existing uses. Scale 1:2.000.

Figure 5. Pessequeiro, Martim Longo – Alcoutim. Intervention in the territory: Road Structure and parking area. Scale 1:2.000

Is depopulation a consequence of an aging population? Or is aging a consequence of depopulation? On one hand, young people abandon rural areas looking for opportunities, on the other hand, the lack of youngsters leads to a non-investment (public or private) for this investment is not feasible (lucrative).

In Portugal, inland regions interior will always be different from the coast regions. Different, in regards to the undertaken economic activities or, urban characteristics. These differences may be positive, since they can generate differentiated infrastructure's in the inland regions and promote a balanced revitalization of the territory. Housing structures for elderly people - developed according to a model of community life, like the Retirement Villages – may be one of those infrastructures.

These arise from the response needs in providing quality housing for local elderly and simultaneously the establishment of others, who wish to return to their origins, but seek

differentiated spaces and services; these may also attract other individuals (national or foreign) that intent to spend their retirement in a rural environment. This population increase brings new job opportunities, providing the establishment young people, whom also need different support structures. That is to say, taking one of the characteristics that mark the rural areas, aging population, and we may achieve the answer to another problem: depopulation, by transforming the aging population into an agent for change.

Abstract. *June of 2013 will be remembered in Brazilian history. The main reason for that could be the Confederations Cup held by FIFA and also the victory of the Brazilian team in such tournament. Nevertheless, between June 15th and June 30th of that year, the spotlight turned to the popular manifestations, protests to show disapproval of the perverse socio-spatial segregation processes that inform the history of the country. In order to hold the event, a major transformation of the structure and image of the six host cities – including Belo Horizonte – was necessary. However, it is important to emphasize that these changes are part of a larger process that indicates a concept of city which reinforces the capitalist basis of the property market and consolidates the historical process of social exclusion. In response to dissatisfactions accumulated over many decades, there have been several urban conflicts during FIFA Confederations Cup Brazil 2013 that turned the city into an arena and an object, in order to expose government's mistakes and claim rights. We remark that, when using the key concept "Urban Conflict" we mean any confrontation or dispute relating to infrastructure, services or urban life conditions which involves at least two collective actors and/or institutions (including the state) manifested in public space. This research is one of the subject areas of the Urban Conflicts Observatory. The main objective of this research is to analyze the urban conflicts that happened in Belo Horizonte during the FIFA Confederations Cup Brazil 2013, according to data and studies developed by the Urban Conflicts Observatory of Belo Horizonte.*

Keywords: Urban Conflicts; FIFA Confederations Cup Brazil 2013; Belo Horizonte.

Introduction

The Confederations Cup 2013, just like the 2014 World Cup, demands the fulfillment of a long list of requirements and recommendations made by the International Federation of Association Football (FIFA), ranging from technical issues related to the host stadiums and their surroundings (easy road access, proper public transportation and hotels near the airport), infrastructural issues (transport and telecommunications) to budget issues (the local government and the country's football federation must bear the costs regarding infrastructure). Therefore, many public works were started and planned in preparation for the events. An institutional arrangement was made, with new organizational departments and organizational committees at the national, state and local governments, and also partnerships with private companies (Alvares *et al.*, 2013).

These major sporting events have led to the transformation of the games host cities in Brazil. Football stadiums went through great improvements, since the government was aiming to meet the stadium requirements made by FIFA, such as expansion of their seating capacity, improvements in infrastructure, fire systems, among others.

¹³¹ This research is funded by UFMG (Universidade Federal de Minas Gerai), FAPEMIG (Fundação de Amparo à Pesquisa do Estado de Minas Gerais) and CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico).

Moreover, urban plots were dismembered to set new systems of public transportation and to expand the existing ones. Families were expropriated to make room for the construction of public works related to the events, being these areas, in most cases, interesting in the housing market.

It is emphasized that the occurrence of such mega events in the country, as well as the transformations they brought, are part of a larger context that involves new ways of thinking cities. Hence, these new local-global relations would be leading cities towards the adoption of policies and practices that would ensure their integration into the globalized world.

“We notice that the worldview that is imposed, in contemporary times, is covered with a kind of economic rationalization and the logic of the market begins to dominate consciences and permeate new discourses that arise. An arsenal of keywords and/or key concepts, to begin with the so-called globalization, an established belief that is often justification for thoughts and attitudes, and also means maximum growth, productivity and competitiveness appear in recent times as background of a context where the business/commercial realm is practically imposed to the most diverse discursive fields, also gaining strength in practice performances that refer to space in general”. (Gonçalves, 2005, p.42).

However, we can observe the engagement and the work carried out by groups that resist the current processes in progress. Among them, the Popular Committees of the Cup and the Olympics and its National Articulation (ANCOP) stand out, since they contributed prominently to build a collective consciousness about the fact that those mega events are a burden for the Brazilian population, as they lead to the deviation of resources from priority sectors (Vainer 2013).

Against the backdrop of the new perception of the events that were being developed in the country and bringing up dissatisfactions accumulated over many decades, there have been several urban conflicts during FIFA Confederations Cup Brazil 2013 that turned the city into an arena and an object, in order to expose government's mistakes and claim rights. We remark that, when using the key concept “Urban Conflict”, we mean any confrontation or dispute relating to infrastructure, services or urban life conditions which involves at least two collective actors and/or institutions (including the state) manifested in public space. This research is one of the subject areas of the Urban Conflicts Observatory under the leadership of ETTERN laboratory of the Institute of Research and Urban and Regional Planning – IPPUR, of the Federal University of Rio de Janeiro - UFRJ. One component of this network is the Centre of Urban Conflicts of Belo Horizonte, created in 2006. With this paper, we aim to analyze the urban conflicts that happened in Belo Horizonte during the FIFA Confederations Cup Brazil 2013, according to data and studies developed by the Urban Conflicts Observatory of Belo Horizonte.

The Confederations Cup 2013 in Brazil

The Confederations Cup is an event held every four years by the International Federation of Association Football (FIFA) and was held in Brazil in 2013, between the 15th and 30th of June. It was supposed to be an experimental event, prior to the hosting of the World Cup 2014.

The cities chosen to be the hosts of the event were Rio de Janeiro, Fortaleza, Recife, Brasília, Salvador and Belo Horizonte, whose major works and projects are briefly presented below.

Rio de Janeiro, city whose governor considered the Confederations Cup 2013 a rehearsal for their major projects for the World Cup, failed in his intention. The Cup happened and the only public work that was completed in time for the occasion was the Maracanã stadium, which cost twice what was anticipated in the original budget (from BRL 600 million, the budget was brought to BRL 1,049.00 billion, according to the state government). Besides, this stadium, that held the final match of the Confederations Cup and will also hold the final game of the World Cup, had a test match canceled and was inaugurated on the eve of the competition. The intention to expand the stadium capacity to 200,000 people was also not achieved, as it was reopened with a maximum capacity of 78 thousand supporters (Estádio, 2014).

The other public works anticipated in the original Responsibility Matrix of the Sports Ministry were postponed until the competition of 2014, for example, Antonio Carlos Jobim International Airport, the Galeão, whose improvement works were not finished by the beginning of the Confederations Cup and had its privatized services started only in September 2013. The new expected delivery date, according to the city of Rio de Janeiro, is the month of April 2014 (Portal Da Copa, 2014).

The Bus Rapid Transit (BRT) in Rio – Transcarioca – a project that involves the construction of an express corridor connecting Barra da Tijuca to the international airport, was 85% complete by the time the Confederations Cup started.

Rio de Janeiro wasn't even able to conclude its projects related to tourism in the city. The evaluation of the Brazilian Hotel Industry Association of Rio de Janeiro (ABIH - RJ) showed that only 70% of the 33 thousand vacancies of hotels in Rio would be filled during the Confederations Cup, and that the host capacity of the hotels will be increased for the World Cup, with over 10.000 new vacancies (Associação Nacional De Transporte Público, 2014).

In Fortaleza, also a host city, there were many pending projects by the time of such event, particularly related to mobility in urban environments surrounding Castelão Arena. In front of the stadium, the biggest of the public works (an overpass that was supposed to connect two major avenues) was shut down during the event. In a statement, the Ministry of Cities asserted that some of these great works will not be ready for the World Cup 2014 (MOBILIZE, 2014). The main urban mobility work in Fortaleza is the Light Rail Transit route (LRT) that has not been completed yet, and also the BRT along with its four projects, totaling 20 km and that will lead to the expropriation of 144 families to give space to a line of 3 km; the works of the Mucuripe port and the airport of Fortaleza, Pinto Martins, were also delayed when the Confederations Cup started (Mobilize, 2014).

In the city of Recife the numbers were around USD 918 million, according to the Responsibility Matrix. The works involve the Caxangá Corridor, that will become the main access of public transport by bus to the Pernambuco Arena, besides other projects related to buses, road transportation and the remodelling of Gilberto Freyre International Airport of Recife and also the port (Portal Brasil, 2014). The Pernambuco Arena was not complete during the games of the Confederations Cup and is still in the works, according to Portal da Copa 2014.

In Brasília, public works regarding urban mobility and improvements in Juscelino Kubitschek International Airport and the Mané Garrincha National Stadium were proposed. At first, a Light Rail Transit route would be built in the Federal capital, but the work was stopped due to irregularities concerning public bidding and ended up being removed from the Responsibility Matrix.

The city of Salvador had expected investments of BRL 172.00 million (Responsibility Matrix, 2010), which would be distributed between urban mobility works and improvements on the airport and the port. By the time of the Confederations Cup, a major part of such public works was delayed and/or unconcluded. We observe, therefore, that the cities were not fully prepared for the event.

Besides these five cities, Belo Horizonte hosted the FIFA Confederations Cup, whose projects and conflicts that occurred during such event will be presented below.

The Confederations Cup 2013 in Belo Horizonte

In the city of Belo Horizonte we can highlight some projects related to mega-events (Image 1), namely: the improvement of the Magalhães Pinto Stadium – Mineirão (1), the expansion of the International Airport (2), the creation of the Liberty Square Cultural Center and the revitalization of Savassi (3), the implementation of the BRT (Bus Rapid Transit routes), the transport corridor linking Pedro II avenue to Carlos Luz avenue, linking Route 210 (between Via do Minério and Tereza Cristina avenue in the west region) and linking Route 710 (connecting Andradas avenue to Cristiano Machado avenue) and Boulevard Arrudas to Tereza Cristina (Alvares *et al*, 2013).

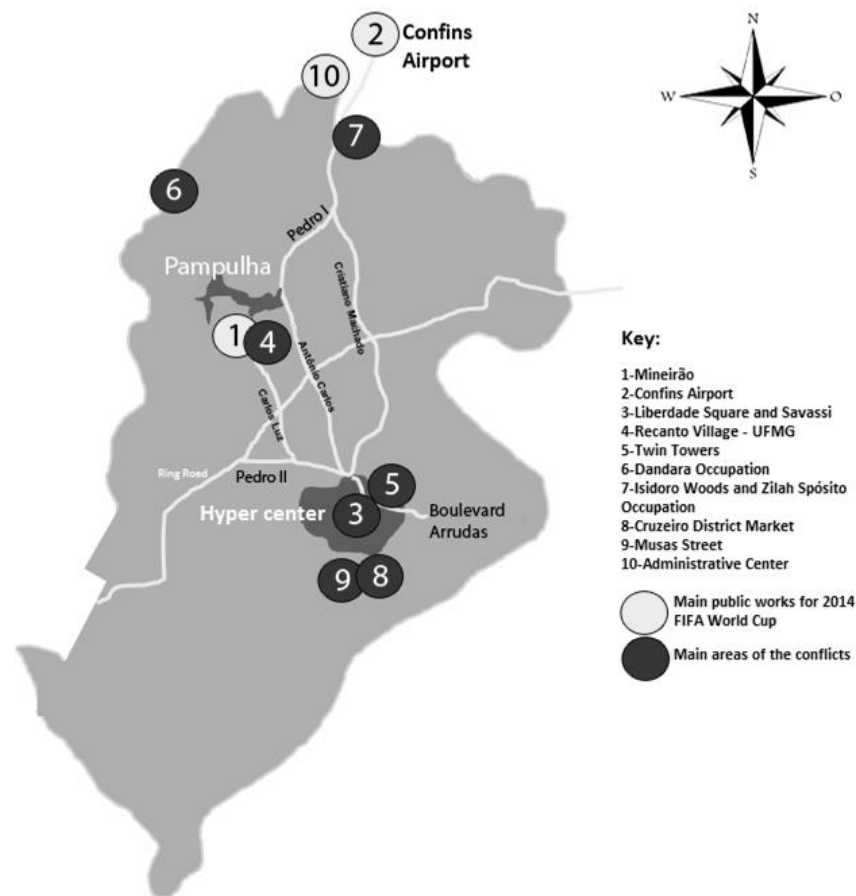

Figure 1. Location of the main projects in Belo Horizonte and conflicts due to the World Cup 2014 mega-event (source: Authors, 2014, based on Alvares et al, 2013).

The remodeling of Mineirão Stadium was completed on 20th December 2012, after two years and ten months of stoppage, with an expense of BRL 666.3 million. The Stadium is a preserved historical heritage of Belo Horizonte and therefore its original design, inaugurated in 1965, was not modified. However, some significant changes were made, for example, in its outdoor area, which currently contains an esplanade of 80.000m², called "Mineirão for All", with capacity for 65,000 people. The "New Mineirão" has better uses than before, since it now contains panoramic restaurants, 58 bars and snack bars, luxurious locker rooms, high definition screens; the field was lowered by 3.4m to improve its visibility, but its internal capacity decreased from 64,000 to 62,170 covered seats and 98 loges (Portal Transparência, 2014).

The BRT - Bus Rapid Transit implementation works were initiated on important roads of the city in 2010 but were not completed during the Confederations Cup, estimated period for the completion of such project. The construction of the BRT caused major detours and traffic problems, besides the expropriation of residents, especially in the vicinity of Pedro I avenue, which caused dissatisfaction among the population of Belo Horizonte.

Since the connection that the BRT would enable – between the center of the city and the Confins International Airport, located in the north of the Metropolitan Region (40 km far) – was not performed in time for the Cup, supporters who hoped that the city would be able to welcome visitors and provide quick and economic system of transportation were distressed. It is noteworthy, however, that the biggest losers were the inhabitants, workers and everyday users

of public transport and roads majorly affected by the works. The increase of time spent in traffic was significant and the delay in completion of those works made the situation worse.

Thus, the solution to a system with insufficient means of transportation to serve the supporters of the event was to facilitate the use of buses for those who would watch the games at Mineirão Stadium and issue decrees creating holidays, mostly because of the protests made by the population to show their dissatisfaction with the occurrence of the events in Belo Horizonte.

Regarding the promised subway expansions, its project began with surveys on routes throughout the city, but nothing was done besides that.

In order to stimulate the hotel business, Belo Horizonte established the Urban Operation (Law n. 9952/10), a "stimulus to the development of health infrastructure, cultural tourism and business, to meet the demands of the World Cup" in 2014. Thus, the city, that had 17,920 vacancies, was expected to increase that number to 31,240. The laws regarding such operation, when setting quite permissive urban parameters, fostered the construction of buildings considered out of the current context of Belo Horizonte, since minimum bedrooms were offered on abusive prices (Jornal Estado De Minas, 2014).

The dissatisfactions accumulated over decades, the changes aforementioned, as well as other modifications in the urban landscape of the state capital generated a remarkable grievance among the population and, consequently, several urban conflicts, manifested during the Confederations Cup.

Urban conflicts manifested in Belo Horizonte during the FIFA Confederations Cup 2013

There are several groups and residents who have been "affected" by the Cup and the public works it demanded. In line with other movements in other host cities, by the end of 2010, the Committee of People Affected by the Cup in Belo Horizonte (BH-COPAC) was created, as a way to group the various people and groups negatively affected and articulate their demands. COPAC-BH is part of the National Articulation of Popular Committees for the Cup, which comprises all Brazilian host cities and released, in December 2011, the Mega-events and Human Rights Violations in Brazil dossier, denouncing a number of systematic violations perpetrated by governments and their partners against population at three levels (Alvares *et al*, 2013).

According to Álvares et al (2013), arbitrary actions have been reported in the blogs of local committees (as for Belo Horizonte, the <http://atingidoscopa2014.wordpress.com/>) and at the Portal da Copa (www.portalpopulardacopa.org.br). In June 2011, along with the "Freedom March", different groups that compounded COPAC - BH protested in downtown Belo Horizonte against the social impacts caused by the Cup, requiring – among other things – an end to evictions and expropriations, as well as demanding popular housing construction rather than hotels.

The timing of the occurrence of the Confederations Cup ended up encouraging mass outbursts of protests throughout the country. Most of them were connected to COPAC and questioned the social impacts caused by the realization of the Confederations Cup 2013 and the World Cup 2014.

In this period, the Urban Conflicts Observatory of Belo Horizonte researched 134 conflicts, dated 13 of June 2013 to 31 of July 2013. This data collection was done by consulting the electronic newspapers: O Tempo online, Portal UAI - Estado de Minas, Portal PBH (DOM – Diário Oficial do Município), Portal globominas.com - MGTV and Portal Alterosa. The conflicts spread throughout the city, as it can be seen in Table 1. Among the chosen areas (Table 2), 28% of the conflicts occurred in the city center and 17% in the Center-South

Region¹³², where most part of the public agencies of Belo Horizonte are located. In addition, big public parades of protest occurred significantly throughout the city (15 %), starting in distant districts, heading to the center and neighborhoods of the Center-South Region and ending at the City Hall, in the central area.

Table 1. Areas of the conflicts, June and July 2013 (source: Authors, 2014).

Table 2. Areas of the protests, June and July 2013. (source: Authors, 2014).

Most protesters demanded the repudiation of the abuse of political power and also the explanation, by the authorities, of alleged misuse of public funds and corruption schemes.

Based on Table 3, we notice that the majority of conflicts (27 %) had multiple objects ("other"), regarding the dissatisfaction related to the government's implementation of projects and public works for the Confederations Cup according to FIFA rules, instead of those related to education and health. The protests with multiple objects were eventually criticized and led to the discussion regarding the protesters "lack of focus".

¹³² Belo Horizonte is divided into nine regional administrations (Barreiro, Center-South, East, Northeast, Northwest, North, West, Pampulha and Venda Nova), according to their geographic positions and occupation history.

Claims concerning transportation (18%) were also recurring subjects during the Confederations Cup. Protests to demand the increase of the half fare bus pass program gathered a number of protesters since the outbreak of such protests in June.

The outrage began after the government's assertion that the half fare bus pass program would serve 95,000 students, when the actual number would not reach 8,000. Students demanded meetings with the mayor, requiring plebiscite on free fare in the city.

Furthermore, movements were organized to discuss the public transport systems in the capital and to discuss bus fare costs.

The grievances of employees of private and state companies were also expressive. Workers of the BRT (Bus Rapid Transport) public works, for example, made several stoppages and threatened to go on strike to demand better working conditions.

Health issues were also widely questioned (7%) and, as one of the responses, the Federal Government released the More Medical Doctors Program, for which foreign doctors were recruited to work in the country, especially in areas where medical services are scarce and lacked professionals or urban infrastructure.

Issues regarding education were also widely questioned (7%), ranging from the infrastructure of public schools to the increase in the number of schools vacancies and wider recruitment of qualified teachers. Along with the discussion related to education, there was a discussion concerning the share of GDP that is spent on education and also the proposition of increasing the share, which is currently 7%, to 10%.

Table 3. Objects of the conflict, June and July 2013 (source: Authors, 2014)

Concerning the mobilized groups (Table 4), most of them are "residents or neighbours" (24%). Therefore, remarkable are the protests of squatters – who questioned their rights in order to evoke a response from the Local Government – as well as the new land occupations and squats that happened during this period.

Professionals from the same area (15%) also joined to protest for better working conditions and some peculiarities in each area: the Organic Law for Police Officers; the return of fare collectors on Sundays and holidays, concerning the demands of bus drivers; the complaints of the Brazilian doctors related to the More Medical Doctors Program and the work overload of health professionals; public transportation vouchers and overtime work concerning waste collectors; salary increase and guarantees required by employees of banks; among other issues that arouse during this episode of massive dissatisfaction.

The number of students who went to the streets to protest was also significant (11%), since they showed a politicized attitude and outrage at the events that occurred in the country.

What draws attention in Table 4 are the "Other Social Movements" (10%) that include the population and the citizens as a whole, in addition to other types of movements and appearances of other existing and not recognized associations. Included in this category are people who were expropriated, either due to the BRT, to another public work made by the Municipality or because they were expropriated from areas which are interesting in the housing market.

We also emphasize the meaninglessness of the Syndicates, labour unions and professional associations (6%). In fact, we noticed protests characterized by little premeditation and euphoric outburst, in a certain way, as well as the rejection of partisan organizations.

Table 4. Mobilized Groups, June and July 2013 (source: Authors, 2014)

Regarding the means of protest (Table 5), 21% of the outbursts occurred as parades, especially in the aforementioned areas. Another significant means of protest was the closure of public roads, totaling 17%.

It is noteworthy, however, that the most common mean of protest was the outbreak in public squares (23%), drawing the attention of people who were passing by strategic locations of the city and encouraging the participation of people who were often unaware of the causes of such protests.

Depredation was little used, totaling 2% of the means of protest, but reverberated in society. Repression by the police force was significant and the protesters themselves repudiated depredation, understanding that such actions disqualified them and emptied their speeches, always full of claims.

Table 6 indicates to which institutions the complaints were made. The majority, 40% of the complaints, was directed to the Local Government, which explains the protesters choices to make outbursts in the Center and Center-South Regions, since the City Hall is in the center of Belo Horizonte, such as other public facilities where population claimed their Objects of the Conflicts. 13% of them were directed to the State Government, mainly due to the public works on roads and other structural changes, and 11% of the claims were directed to the Federal Government, which can be related, above all, to the problems in the housing programs, deemed ineffective and inefficient.

"Whole Society" represents a percentage of 11% and sums up the widespread outrage and generalized dissatisfaction, which were amplified in the given period.

The total of 7% concerning the Private Company as target of the claims represents the union of professionals from the same area, calling for improvements in working conditions, and also by users of such companies demanding the improvement of the companies' services and questioning the price of the service and the treatment given by companies.

Table 5. Means of Protest, June and July 2013

Table 6. Target of the claims, June and July 2013 (source: Authors, 2014).

Conclusion

Understanding the conflicts manifested in a area involves understanding the context that led to their emergence.

In recent times, Brazilian cities, often based on the adoption of international standards, have been seen as productive platforms and economic vectors, being designed within the construction and reproduction of competitive advantages and development of strategies that will ensure them a favorable position amongst the global intercity competition space. These ideas can be related to a neoliberal scenario and can be translated by the "urban entrepreneurialism".

Interventions related to communication or other activities connected with the global economy (information, quality of public services, culture, accessibility) are gaining space within the contemporary context and are, in most cases, nothing but specific interventions (which indicates that the general plans are little emphasized) of monumental or symbolic character - huge visible works that can be turned into spectacle. We can notice that the urban policies should be instruments capable of placing the city in the best possible way to seize opportunities, identify and promote its main attractions, according to the current propositions.

Ergo, the mega sporting events - the FIFA Confederations Cup 2013 and World Cup 2014 - fit into the picture, since they provide visibility to a country and its host cities. To attract investment, tourists and capital - that is the justification for such events.

However, it is noteworthy that the huge urban projects which are conceived and executed based on new planning models and also to meet the demands of the mega-events, in Brazil, have been reinforcing the capitalist basis of the property market and consolidating the historical process of social exclusion.

Increasingly, public spaces generated by such interventions are presented as spaces which are not accessible to a major part of the population - for example the Stadiums that cost billions and the prices of the tickets, which are not compatible with the reality of most residents. Also worthy of notice is the incentive given to the hospitality industry in Belo Horizonte, in disregard of the real needs of the city. Another example can be the public funds spent in spectacular public works for the Cups if compared to the neglected sectors of health and education in the country. Our current projects end up promoting a kind of urban "sanitization" in social terms, i.e. expelling groups that occupied certain areas of the city to distant places, far from the areas which are interesting in the market and that are only revalued after the urban "regeneration" or "renovation".

It is clear that these models that emerge in recent times, supported by the idea of the inevitability of competition between municipalities, present themselves in a convincing and hegemonic way. One should, however, consider other possibilities that are presented in the same context. In this sense, to evidence and understand the conflicts and events that took place in Brazilian cities, intensified during the 2013 FIFA Confederations Cup, can help to change the course that the aforementioned socio-spatial issues are taking in the country. Describing and enhancing the conflicts of a city are means of listening to what the city has to say. What happened in Brazil in June and July of 2013 brought to the surface some issues related to historical and recurring problems and showed the negligence, by the government, of one of the most fundamental rights - the right to the city. After all, for whom is the Cup? Who wins and who loses? For whom is the city?

Therefore, we must rethink the city based on concepts such as minimization of social exclusion and, considering the importance of citizen participation in the processes of management and planning, this path can be longer and more complex, but fairer. Pondering the particularities and historical and cultural realities of each place can expand the possibilities of effective and efficient action and may also contribute to the disruption of the historical process of reckless use of formulas and ready models.

Urban morphologies of alternative spaces: a case study of Tehran

Babak Soleimani, Alexandra Staub

Stuckeman School of Architecture and Landscape Architecture, Penn State University, University Park, PA 16802 USA. E-mails: bxs386@psu.edu, acs11@psu.edu.

Abstract. *For the past century, Iran has been characterized by an intense social polarization: on the one hand, those who claim a traditional, “Islamic” lifestyle, on the other those who champion a modernization akin to Westernization. This paper examines how the two forces have played out in shaping the physical spaces of the capital city, Tehran. The urban transformation of Tehran initiated in 1934 aimed, among other things, to restrict the cultural activities and public life of a traditional urban class in favor of a Western-oriented elite. The Iranian revolution of 1979 attempted the reverse: with similar procedures but with different outlooks, the revolution reinserted traditional culture into the public sphere and marginalized non-traditional subcultures. Both after 1934 and again after 1979, particular urban settings have played a key role in the form of “alternative spaces” that enabled the marginalized social group to preserve the vitality of their lifestyle. Using a case-study approach, this paper examines the ways specific aspects of urban morphology have contributed to the formation of these alternative urban spaces. Through a parallel analysis of Tehran’s Grand Bazaar and Ekbatan housing estate, this study posits that urban boundaries shaped by physical structures have been a significant factor in the formation of these alternative social spaces. The outcomes of this research shed light on the interrelationship of physical and socio-cultural landscapes in socially contested cities.*

Key Words: Iran, public spaces, social transformations, Bazaar, Ekbatan.

Iran’s cultural dichotomy

Iran has experienced two cultural upheavals in the past 100 years: a radical “modernization” in the 1920s and 1930s, and the Islamic revolution of 1979. Both led to vast transformations in the structure and use of public spaces in the capital city of Tehran. It was Shah Reza Pahlavi (1921-1941) and his son Mohammad Reza Shah Pahlavi (1941-1979) who forcibly modernized Tehran through both cultural and economic reforms as well as physical changes, including a new Western-style matrix of streets superimposed onto the old urban fabric. After the Islamic revolution in 1979, the new government, promoting a more traditional society based on religious values, shifted this social and cultural framework to limit the manifestation of a Western-oriented lifestyle in public spaces. Both conditions resulted in the polarization of the city, a strengthening of spatial dualities and the marginalization of certain groups in society.

Several studies have been dedicated to the spatial conflicts and territorialization of public spaces, both in the pre-revolutionary and post-revolutionary time periods (Mowlana 1978; Abrahamian 1982; Keshavarzian 2006; Amir-Ebrahimi 2006). Often the focus has been on the socio-economic processes that result in the internalization of public activities, or manifestations of resistance in public spaces. However, the role of spatial factors has often been neglected in these studies.

We aim to contribute to this body of work through focusing on the socio-spatial processes in the city. In this, we have studied Tehran’s conflicting conditions based on a parallel study of morphological, social and cultural transformations since the 1920s. We have investigated urban boundaries that segregate space in the city of Tehran from a socio-spatial point of view, in order

to explore the paradoxical relationship between governmental powers and people's actions in public spaces.

This paper focuses on the process of spatial segregation and internalization as a reaction to governmental control in two different and even contrasting historical and spatial settings: the Grand Bazaar of Tehran during the Pahlavi period, and a large residential complex named Ekbatan in the years after the 1979 revolution. We argue that the spatial segregation of these structures from their urban context blocks the homogenizing and controlling power that dominates the rest of the city, allowing the formation of an alternative socio-cultural landscape. Thus, despite significant variations in their mechanisms, these urban zones have become the spatial manifestation of the conflicting dualities that shape the power struggle in Iranian society.

Before 1934, the structure of Tehran was comparable to that of other traditional Iranian cities: surrounded by defensive walls, and with a bazaar that ran through residential neighborhoods, connecting a southern city gate to a citadel located in the north (Figure 1).

Figure 1. Map of Tehran and the Old Bazaar in 1859. Arrows shows the gates. Bazaar connects the main streets that are connected to Tehran's gates Source: Author reproduced from the Map of Tehran in 1859 Available from <http://geographyscience.persianguig.com/Map/>.

Transformations in the Pahlavi era dramatically changed the face of Tehran. In 1937, the walls and the twelve main gates of Tehran were demolished to open the city for future growth (Madanipour 1998). A matrix of wide and straight boulevards was superimposed onto the traditional urban fabric, destroying some parts of the Grand Bazaar (Figure 2). Replacing old narrow streets, these new boulevards gradually became the main channels of transportation in the city, as well as providing a backdrop for a new urban life. Through linking a series of squares, the new street network accommodated an increasing number of cars and facilitated the flow of traffic within Tehran (Mirgholami & Sintusingha 2012).

Parallel to this physical transformation, widespread socio-cultural changes were under progress. A new Western-oriented consumerist life style started emerging in Tehran, while religious spaces were replaced with new institutions. Reza Shah's reforms provided a basis for secularization in Iranian society, a lifestyle that required new public spaces (Abazari et al. 2007).

Figure 2. Map of Tehran 1944, reproduced by Author from: <http://nimrouz.com/blog/?p=618>, Accessed on May 14, 2014.

Secular institutions defined new zones for social life through providing public spaces. Through offering new forms of sociability and entertainment, these spaces implied a rejection of traditional lifestyles. At the same time, new activities expressed Western cultural components that were in conflict with the values of a traditional society. The hierarchical network based on social structures and public-private relationships in cities was replaced by a gridded network of streets that created homogeneity through connectivity (Madanipour 1998). The public realm, which was previously concentrated in the bazaar and its vperipheral urban structures, became a widespread network of orthogonal streets distributed across the whole urban fabric, and bordered by new commercial venues on both sides.

Social, political, cultural and urban transformations shaped a polarized public sphere in society. A fresh lifestyle started emerging under a new capitalist mode of production, as well as growing relationships with countries abroad. Exposed to modern ideas and cultural products, a new urban class was seeking a new identity. This was contrasted by traditional parts of society, who were following their own culture and beliefs. The foreign ideas, products and cultural manifestations brought in by the Shah were perceived suspiciously, and rejected unless confirmed by major clerics. These rejected a significant part of the new activities and products that were being promoted as part of a modern lifestyle as “immoral” and “non-Islamic”.

After the revolution of 1979, Iranian society saw a return to traditional values as a basic theme for cultural policies. “Modernity” and “secularity” were replaced with “Islamic” in public spaces. While cities did not face major physical changes, new policies limited Western cultural products, encouraged women to concentrate on domesticity and motherhood as their main responsibilities, and ended cultural secularization by bringing religious values back to the public realm. Rules and regulations were established to reinforce new codes of appearance and behavior in public spaces including traditional dress codes for women, separation of men and women in public spaces, prohibition of music and dance performances, and the prohibition of alcohol.

The cultural policies critically changed how people used public spaces, especially in large cities. The new codes significantly limited the continuity of the modern life style that had taken shape during the Pahlavi years. Spaces for non-traditional forms of interaction, including bars and clubs, were closed. Major urban spaces, such as squares, streets and parks, became a stage for implementing new codes. The controlling power was being transmitted through the urban network into the public realm of the cities, where even without the presence of police people were expected to respect the new rules (Amir-Ebrahimi 2006).

This controlling power shaped a paradoxical condition for public urban spaces, in which the most integrated urban spaces, i.e. those with the highest visibility, were at the same time those that were the most controlled. This paradox significantly changed the relationship of public to private life in society: home, as the most private space with private ownership, allowed freedom, while urban spaces became a stage where control would be exercised over one's behavior and appearance. In this sense, the meaning of visibility, usually associated with security, shifted to represent the insecurity of constant control through the moral police, neighbors, and community (Amir-Ebrahimi 2006).

The Grand Bazaar

The bazaar in Iranian society is a traditional market with small, individually run stalls, but was traditionally also the area for extra-familial sociability, public life and urban activities (Ashraf 1988). The bazaar usually consisted of a number of covered linear streets, interspaced with enclosed courtyards, small squares, and cross roads. This system provided access to major public buildings located within the bazaar, including mosques, public baths, cafes and gymnasiums. For this reason, the bazaar also played a significant role in the structure of Iranian cities. Tehran's bazaar is comparable to that of other Iranian cities, and to this date it contains all the original components of a traditional bazaar.

In Iran, the bazaar is recognized as the main core of the city. It is the extension of major streets in the city, which can be read in the continuity of the urban street system. Its central location in Iranian cities has a significant role in the formation of the bazaar's distinctive role as the center of social activities. The bazaar acts as an axis that connects different segments of the city through its linear structure.

Passing through the gates of the bazaar marks a major sequence within the city, that of moving from a publicly owned street to a seemingly privately owned and controlled urban structure. In this sense, the bazaar creates a paradoxical situation: it is the most sociable and the most integrated part of the city, while at the same time being owned and controlled by *bazaaris* (merchants who work in the bazaar), and protected by gates. The bazaar thus becomes a pseudo-public space in which activities, behaviors and appearances are highly controlled. Through their daily use of the spaces that comprise the bazaar, the merchants who work there have complete control over the behaviors and activities that take place in this space. The *bazaaris'* traditional outlook is reinforced by clerics, whose close relationship with *bazaaris*, allow them to have a significant role in controlling public spaces.

The transformation of Tehran in 1937 included ideas for controlling the urban fabric through the ease of access for troops; however the bazaar remained intact and, to an extent, untouched by this policy. Yet the attempted integration of the bazaar into the larger urban network became, for Iran's traditional society, an attempt to merge them into a Westernized lifestyle that was in contrast with their culture and beliefs; the attempted control over the space of the bazaar was thus perceived as an attempt to create a homogenizing network that would allow the government to flow its power into all segments of society.

The urban transformations of 1937 changed the spatial role of the bazaar within the city. The urban matrix shifted the public realm to the new streets.

The urban grid plays a major role in the patterns of use in a city (Hillier et al. 1993). Based on the space syntax theoretical framework, theory of natural movement investigates the relationship between pattern of using urban spaces and the spatial layout of the urban grid. Using space syntax's axial-line analysis, we show the change in the bazaar's integration level and changing role into the urban fabric before and after the transformation. The axial line analysis of the Tehran map of 1859 reveals that the city's urban core matches the location of the bazaar. The main axis of the bazaar have the highest integration value ($R_n = .81$), while other highly integrated lines are located on further streets of the bazaar. The integration value of the bazaar is much higher than the mean integration level in 1859 Tehran (which is $R_n = 0.51$) and

reveals the relatively central role of the bazaar in the urban structure of Tehran at the time (Figure 3). The urban transformation of 1937 shifted the core of the city from the bazaar to the new matrix of streets. After the transformation, the bazaar's degree of integration ($R_n = 1.59$) became less than the average degree of integration ($R_n = 1.64$). The urban integration has been shifted from the bazaar to the new major streets in the city, including Boozar-jomehri (later Panzdah-e-Khorded) ($R_n = 3.03$), Shapoor (later Hafiz) ($R_n = 2.89$) and Pahlavi (later Vali-asr) ($R_n = 2.96$) (Figure 4).

Figure 3. Global integration map of the City of Tehran based on the map of 1859. Main axis of Bazaar is marked by a circle. Source Author Reproduced from <http://geographyscience.persianguig.com/Map/>.

The other reason that the bazaar became more segregated within the city was the fact that without major destructions, the narrow and irregular streets of the bazaar were not compatible with the new vehicle-based transportation system in Tehran. Supported by clerics and traditional social groups, the *bazaaris* resisted the demolition of the bazaar, and any attempts at major reconstructions remained ineffective. Thus, movement within its spaces remained pedestrian-based and separated from the urban transportation system.

Despite its declining economic significance, the bazaar as the core of public life found a critical new role. Resisting external pressures, the bazaar gave an alternative space to traditional segments of society, allowing them to keep the vitality of their rituals, culture and belief. Without access to the new mass media, traditionalists relied on the bazaar and its subsidiary spaces as a channel of public communication (Mowlana, 1979). The bazaar was thus promoted from an economic center to the powerful basis for spreading cultural values of the traditional parts of society.

Urban transformations turned the bazaar from the spatial core of the city to a segregated shell protecting its spatial, economic, cultural and social structure from the life of the streets beyond. Urban transformations in the old urban fabric were a tool for integrating these areas into the larger socio-economic system promoted by the government and other modernizing forces within society. The coherent space of the bazaar protected the network of public buildings and religious spaces that functioned as the cultural and intellectual center for traditional elements of society, and provided space for the traditional rituals and beliefs that were being promoted inside the bazaar.

The bazaar's significance for traditional parts of society was also symbolic. The city's new public spaces, through their resemblance to European streets and through offering new forms of sociability, were perceived as a break from the past and as advocating "modernity", "connectivity" and "engagement with a developed world." In this system, the bazaar found symbolic meaning as the dynamic continuity of traditional values and meanings.

Figure 4. Global integration map of the City of Tehran based on the map of 1944. Main axis of Bazaar is marked by a circle Author from: <http://nimrouz.com/blog/?p=618>.

Ekbatan housing estate

The revolution of 1979 established restrictions over public appearances and behavior. As the rigidity of these codes declined somewhat after 1989, the rigorous distinction between the private and public realm of life shifted, and a new type of public space emerged that, while still controlled, allowed people to express themselves and act with a higher degree of freedom than in the city's most visible public spaces. This new type of space was usually privately owned yet open to the public, with less control over patrons' activities, appearances and clothing. Shopping centers, coffee shops, cultural centers, art galleries and restaurants were among these spaces.

Residential complexes in Tehran are the largest privately-owned spaces that are open to the public. In this study we focus on Shahrak-e-Ekbatan, the largest residential complex in Tehran, to investigate the role of urban boundaries in its spatial segregation from the city. A community planned as several building phases by American architect Jordan Gruzen in the 1970s, our analysis concentrates on Phase I of this complex.

Ekbatan's segregation from the urban fabric has created a space able to allow alternatives to the current top-down system of social control. Bordered by Mehrabad International Airport to the south, Ekbatan is bounded by highways to the north, east and west. The first phase of Ekbatan includes ten distinct blocks straddling a linear market place. This configuration is bordered by a row of trees, which has shaped a green belt around Ekbatan.

The spatial relationship between Ekbatan and its urban context depicts the relationship between residents and the city as a whole. Vehicular access to Ekbatan is possible only through two entries, one from the south and one from the north. The highways surrounding Ekbatan have completely disconnected it from rest of the city; pedestrians are not able to access the complex from outside (figures 5 and 6).

Vehicular traffic within the complex is limited to a single peripheral street that circulates around the complex and provides access to parking. The vehicle access to Ekbatan is possible through two entries from southern and northern highway. Ekbatan is not accessible from outside the region for pedestrians. Figure 7 is an axial line analysis map that shows the degree of integration between Ekbatan and surrounding areas. As can be seen in the axial analysis, the most integrated street is Nafisi Street, located between Ekbatan Phase I and a complex called Shahrak-e-Bime. Interestingly this street was blocked for so many years by a wall to prevent access from Shahrak-e-Bime until the wall was destroyed in 1997. This street was blocked by a

wall until 1997 to prevent access to Ekbatan from Shahrak-e-Bime. Despite this, Ekbatan remains spatially segregated from the surrounding city, and with its large size, the segregation of Ekbatan has shaped a hole in the urban fabric.

Figure 5. Three phases of Ekbatan from “Tehran.”, $35^{\circ}42'31.99''\text{N}$ and $51^{\circ}18'30.59''\text{E}$. Google Earth.

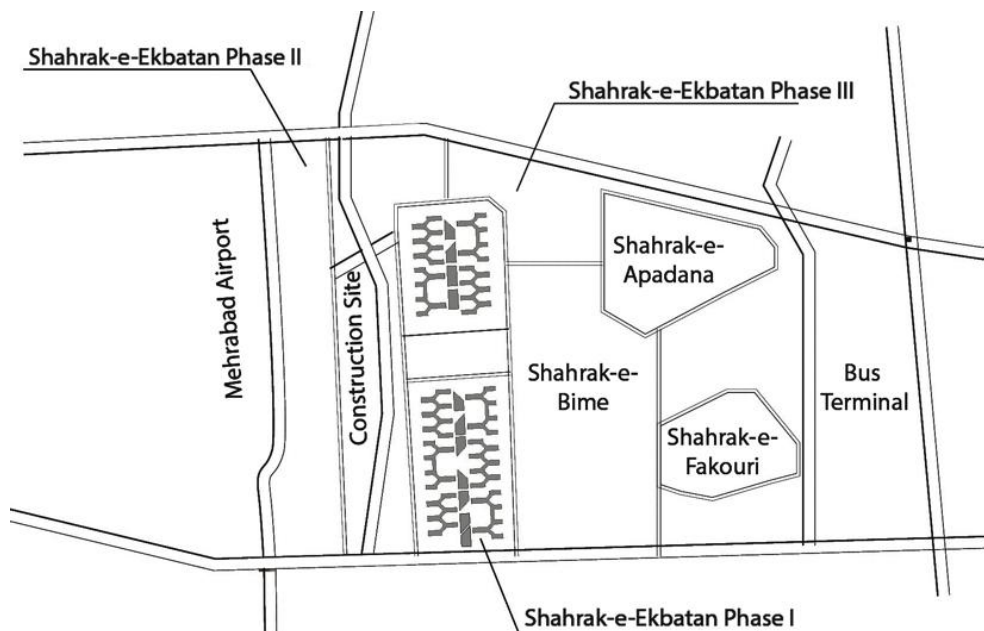

Figure 6. Ekbatan phase 1 is bounded by highways. Source: Author reproduced from “Tehran.”, $35^{\circ}42'31.99''\text{N}$ and $51^{\circ}18'30.59''\text{E}$. Google Earth.

Figure 7. Global integration map of the City of Ekbatan. The street between first phase and Shahrak-e-Bime is the most integrated street which is blocked by a wall, Source Author reproduced from “Tehran.”, 35°42'31.99"N and 51°18'30.59"E. Google Earth.

A layering of space has intensified the disconnection between Ekbatan and the city. Ekbatan's space configuration is based on striation, with transitions from the surrounding streets to the central market associated with crossing several layers of space. Layers provide a set of boundaries that decrease the spatial and visual connections between Ekbatan and rest of the city. These layers shape a shell for Ekbatan and create a visually and physically segregated “inside” (Figure 8).

Through its physical segregation, Ekbatan blocks the flow of movement from the surrounding urban network. Inertia caused by boundaries minimizes social exchanges between Ekbatan and rest of the city. In essence, Ekbatan is a micro-city separated from the main body of Tehran, which has allowed the complex to reject external surveillance and control. Socio-spatial barriers between Ekbatan and the surrounding city have developed the concept of “strangers” and “outsiders” among the residents in Ekbatan; residents use these terms to describe non-residents who use the open spaces of Ekbatan. Residents consider the exclusion of “outsiders” as the main aim behind the formation of a controlled world of familiar people, images and settings that contrast the anonymity and chaos of the uncontrolled world beyond Ekbatan's walls. Residents of the complex consider public spaces a part of their living environment, and the presence of police forces in Ekbatan is considered a violation of their private domain.

The boundaries of Ekbatan not only exclude outsiders but also limit the connection between the residents and the surrounding city. This border has created inertia against going outside Ekbatan, reinforced by the local availability of amenities such as shops and parks, or institutions such as schools and clubs. Thus the immobility of people within Ekbatan, as opposed to the “otherness” of people moving in the surrounding metropolis, has resulted in the locality of activities and relationships. More significantly, limitations shaped by these boundaries are a means of extending individual control over public space. The anonymity of the metropolis is substituted by familiarity and local social surveillance. Adjacency of living areas and public spaces has shaped the residents' high levels of control and dominance over the courtyards.

Residents recognize courtyards as the extension of their territory. In contrast with governmentally sanctioned external control, which Ekbatanis consider a form of restriction, local surveillance is considered as a means of security.

The proximity of public spaces and residential units, as well as the strong social bonds among residents, brings about their dominance over the public spaces. The moral police sent by the government usually avoid interfering in these spaces. In observing behavior taking place in Ekbatan, one sees that activities and appearances are much less hindered in these spaces. Women can be seen without head coverings in public spaces, people walk dogs, otherwise prohibited under Islamic law, and social interactions between unmarried young men and women are common.

The relative exclusion of external controlling forces within Ekbatan has made possible activities that are rarely seen outside. While the hijab¹³³ is mandatory in Iran, women can be seen without Hijab. While taking pets out of home is illegal in Tehran, pets are an impartible part of the activities in Ekbatan. Ekbatan is well known for its subcultures influenced by Western culture. Ekbatan is the origin of *parkour* or free-style running and a major site for *parkour* festivals in Iran. The complex is also known for its graffiti artistry. Concrete walls of Ekbatan are a safe canvas for graffiti artists to show their work. There is a concrete wall in Phase III of Ekbatan which is called “free wall”; it has become a favorite place for graffiti artists. Not surprisingly, a significant number of Western-style underground music groups also work in Ekbatan.

Conclusion

This work has investigated public spaces that, through their spatial segregation, have shaped a socio-cultural landscape different from the rest of Tehran. The two spaces discussed have created “alternative spaces” within two different regimes. While the role of the bazaar, as the core of the urban fabric and the main center for public activities, changed due to the urban transformations and rapid growth of Tehran, Ekbatan was originally imagined to be a segregated, self-sufficient complex. Both the bazaar and Ekbatan create urban voids in Tehran’s transportation network, further increasing their isolation. Both spaces are not accessible by car, while pedestrian and visual access is controlled.

The interrelationships between a top-down system of control and these urban boundaries are different in the two examples studied. Tehran’s bazaar has been symbolically and functionally merged with the public life of the city’s traditional society. The bazaar includes significant public institutions, and administration is provided through the traditional powers of *bazaaris* and clerics. Consequently, the bazaar has remained structurally and semantically engaged with traditional life. Segregation of the bazaar during the Pahlavi era provided an opportunity for preserving the continuity and vitality of a traditional lifestyle within the bazaar. Offering an alternative space inside the city, the bazaar rejected the homogenizing world being shaped outside, and offered traditionalists a controlled environment.

Ekbatan is also secluded from the city through physical borders. Rather than providing a socially controlling environment, however, the complex offers a more liberal environment than that of the city beyond. External control forces are blocked through a lack of vehicular access, creating a basis for a higher degree of freedom compared to the rest of the city. Both the bazaar and Ekbatan have created the opportunity for an alternative system to exist within the greater society. In this, the duality of Iranian culture has existed over time.

¹³³ *Hijab* is a veil that covers the head and chest, which is particularly worn by a Muslim female.

Revisiting urban morphological classics

‘The future has an ancient heart’ is the title of a book written in 1956 by the Italian writer Carlo Levi. I mention it as inaugural metaphor of our session: the classics of Urban Morphology can be considered as the foundations of a building under construction, which will be much firmer and more cohesive than us (who are the builders) we will be able to recognize and focus our cultural debts with the masters who anticipated, with their studies, the complex problems of the urban form. In this respect the language barriers are a severe limitation to the international circulation of the texts of the pioneers of Urban Morphology, who as ‘classics’ should be read, summarized, commented and compared in a systematic way in their chronological sequence, regardless of the language in which were written. It could think out to put in them in a critical anthology, to be published in the future as a further step for the growth of our discipline. Moreover *Urban Morphology* in his collection has already hosted a series of articles aimed just to document the different national traditions of urban studies that preceded the ISUF establishment. Vitor Oliveira in his summary article (Oliveira, 2013) there has provided the references, which I here enclose as useful starting point for this project (which could be called ‘Critical Anthology of Urban Morphology’) to bring to completion in next few years.

Abstract. *This study attempts to throw light on the different approaches to urban design between Saverio Muratori and Ludovico Quaroni, with particular emphasis on the way in which the two architects interpreted the idea of morphology and typology and the relationship between these two concepts, with its origins in the lessons they both received from Marcello Piacentini. The idea of 'typology' for Quaroni¹³⁴ was not to be confused with 'type', in the enlightened sense of the term (investigations of which are legitimate only in the case of monuments), even though, as Quaroni maintained, «the word 'typology' has been confusingly replacing 'type'¹³⁵, perhaps because of the word's aura of scientific fascination». For Quaroni, 'typology' meant simply the study of 'building typologies' and was not to be thought of as a generative process or a 'form-creating form' that was understood a priori – as Saverio Muratori would put it.¹³⁶ Quaroni in his writings usually talks of the 'successful achievement'¹³⁷ of a given building-type, as the result of a spontaneous process of a given urban civilisation. Rarely does he mention the idea of 'morphology-typology', identifying it as an interconnected problem to be examined 'in order to formulate correctly a design process' as is the case, on the other hand, with the Muratori-Caniggia school.¹³⁸ The paper includes some comparative notes on certain of the residential districts designed or built by the two architects, in particular the INA-Casa 'La Loggetta' district in Naples, and the INA-Casa at Magliana, Rome, 1956-57 by Saverio Muratori, and the Casilino residential zone of Ludovico Quaroni, 1963-64.*

Key Words: Saverio Muratori, Ludovico Quaroni, morphology, typology, Rome School of Architecture.

In modern Italian architecture, the work of both Ludovico Quaroni and Saverio Muratori had an important role in defining the relation between architectural typology and the form of the city. The relationship between the two architects has often been described as being fraught by bitter animosity and academic competitiveness; this was demonstrated to a large extent when they both took part in important design competitions at the end of the 1950's, and even more so when they both taught in the Faculty of Architecture in Rome in the sixties. Yet younger critics of architecture saw this apparent conflict as a sign that their opposed ways of thinking and different ways of envisaging architecture derived from their divergent educational background in radically distinct cultural, political and architectural principles.

¹³⁸ Petruccioli A. (1998), *Exoteric, Polytheistic, Fundamentalist Typology*, In *Typological Process and Design Theory*, Akpia, Boston, 9. For a full-scale coverage of the schools, themes and protagonists of the so-called 'morpho-typological schools in architecture and geography, their roots in the Enlightenment (Nicholaus Louis Durand and Etienne Louis Boullée), and their differences – the French school (Marcel Poete, Pierre Lavedan – J. Castex, P. Paerai, J. Depaule), the English (M.R.G. Conzen) and Italian (Saverio Muratori, Gianfranco Caniggia vs Aldo Rossi, Carlo Aymonino)

The well-known designs that they created, in competition, for the Cep residential zone at the Barene di San Giuliano in Mestre in 1959 became almost emblematically an icon of their antagonism, of their wholly different way of imagining and designing cities. However, the urban design projects briefly described in this paper also include the *Villaggio La Martella* at Matera (1951) by Quaroni, the residential district *INA Casa 'La Loggetta'* in Naples (1953) by Muratori, the *INA Casa 'Magliana' I-II* (1957) by Muratori, Quaroni's design for the *Edilizia Economica e Popolare del Casilino 23* in Rome (1964), as well as, naturally, the various designs for the Barene di San Giuliano (1959). I have decided to examine these projects, which are well-documented with drawings and in some cases with photographs, because I feel that they enable us to reconstruct the progress attained by the two architects in their most productive years as regards their different achievements, and also the possible reciprocal influences between them. I believe this owes much to their common educational background, to the fact that they both belonged to the same generation of Italian architects who, since the 1930's, cast doubts on the dogmatic axioms of 'rational' modernism and preferred to speculate on the relationship between tradition and modernity, and on the formative processes of ancient cities compared to those of modern ones.

On closer inspection, both Quaroni and Muratori, even though they arrived at an interpretation of urban phenomena that was based on a different sense of the values involved, always conceived of and worked towards a better form of modern city, and held in their minds, openly or almost unconsciously, the idea of the city that had been handed down to them by their teacher Marcello Piacentini: a city of comprehensive monumentality, which was ensured by the design of the whole, its architectural richness consisting of monuments and 'small town' buildings fused together into a continuous fabric of architectural systems that complemented each other, and that, from the viewpoint of their teacher Piacentini, guaranteed that the entire urban organism was a programmed whole. Yet Piacentini had worked in a historical period and on projects whose themes were completely different from those undertaken by his two best pupils. The judgement of history that has up till now been passed on our two architects means that their ideas and projects deserve an ideologically less specialist outlook than they have so far been given. However, what is primarily needed is a critical and academic perspective that is more open to other academic systems – non-Roman, non-Italian – which for some time now have been observing and studying Italian architecture in a much more attentive fashion, seeing that no major Italian critic (Ernesto Rogers, Manfredo Tafuri and Bruno Zevi are long gone) is capable of using his own, *home-grown*, authoritative interpretation to mediate between Italy and the international critics.

All the preconditions are in place. The recent historical importance given by European and North American critics to Italian architecture from the thirties to the sixties is well documented. I need only cite one instance which points to a potentially new way of thinking about Italian architecture and architects. These are the words spoken by Eric Mumford in 2002¹³⁹ at a conference entitled *Urban Design: Practices, Pedagogies, Premises*, held at Columbia University, exactly two years after the death of Bruno Zevi, the oldest member of the great Italian critics of modern architecture: "Postwar Italian architects developed positions, which in different ways advocated the importance of architecture's relationship to the city and to historic urban culture, themes that continue to resonate in urban design down to the present. In Rome, Bruno Zevi (1918-2000) and Ludovico Quaroni (1911-1987), later joined by the young Manfredo Tafuri (1935-1994), advocated an organic and populist approach to the design of modern cities in which the neighbourhood or "quarter" assumed particular importance." In these few words, the irreconcilable ideological differences between Zevi, Quaroni and Tafuri were dismissed as nothing more than a thin coat of paint over the strong collective identity of modern Italian architecture. They are mentioned only as 'different ways', which did not hide the

¹³⁹ Mumford E., Framing paper delivered for the conference "Urban Design: Practices, Pedagogies, Premises" at Columbia University on April 5-6, 2002. File available at: <http://www.arch.columbia.edu/files/gsap/imceshared/Briefing%20Materials.pdf>

common intention of our twentieth century architects to express ‘an organic and populist’ concept of the city and its design. I am sure that not only Ernesto Rogers (the theoretician of the Italian neo-liberty style), but also Saverio Muratori, had Eric Mumford known them better, would have been included in his list. Naturally, by accepting Mumford’s perfunctory judgement of the heated debates that enflamed any discussion on Italian architecture within Italy itself to the point of almost destroying its vitality, the new critical perspective could start by finding a more cogent definition of the two adjectives ‘organic’ and ‘populist’ used by Mumford as describing the more progressive Italian viewpoint as seen from outside, as he was doing. Because it is actually in the debate on the significance of the *organic* in architecture that Marcello Piacentini, Bruno Zevi, Saverio Muratori and Ludovico Quaroni came together and disagreed with one another, as Lucio Barbera has also revealed in his essay *Ludovico Quaroni e Saverio Muratori, between dialogue and silence*¹⁴⁰; and it is precisely about the meaning of *popular*, in other words the popular culture of the city, that the four architects directly or indirectly disagreed. Piacentini recognised the people of modernity in the mass of the middle class that settled in the new cities, and who made their bonds with tradition the lifeline that helped them face modernity; Zevi fled from any kind of extreme or cathartic political ideology and believed it was each individual’s aspirations towards freedom that acted as a catalyst for the freedom of the urban population and of his own architecture. Muratori looked to the evolution of the culture of building and living, that which was thus anthropologically *popular*, within the processes of nature, the most important philosophy of history and architecture. Quaroni saw the fascination of cities not as a product of the overlapping of dominating, formalist or rationalist cultures, but as being due to the dialogue between these and the adaptive capacity for continual constructive inventiveness of a people without architects, who throughout history countered the restrictions of the dominant way of thinking by finding ever new ways to express the truth of their existence, which is and will always be our own.

Starting from that short quote from Eric Mumford and from my own concise observations, I am convinced that *a study carried out in a different spirit* on Quaroni and Muratori’s academic and design practices, as well as on the differences between them as regards urban design, could be a valuable Italian contribution for everyone, also – perhaps above all – in the non-Italian context.

Returning to the particular aims of my paper, I should remind anyone who is not Italian that in Italy, Quaroni and Muratori are figures (without any critical limitations, along the lines of star architects competing with each other) that are usually mentioned in association with the now mythical open competition for the Cep residential neighbourhood at the Barene di San Giuliano in Mestre in 1959, in which each of them took part as leaders of different groups. An experience that brought to a head their divergence as urban designers, began twenty three years previously. In 1936, the Italian architectural world had come to admire the two young architects who were participating together in the open competition for the plan for Aprilia, a new town on the agricultural land that was created when the Pontine Marshes were reclaimed. Their design did not win, but it was selected by the Milan Triennale for the 1936 exhibition. Pippo Ciorra reminds us that it was their design for the Aprilia Plan, and the different and contrasting designs for the Barene, that are both, after all these years, astonishing in their ability to renegotiate the relationship, or the “indirect dialogue with the urban formulations of the great master of the modern, [...] establishing form as the principal instrument of urban design”¹⁴¹. In between these two experiences, which without a doubt can be seen as important examples of design, we have the project that Saverio Muratori, Ludovico Quaroni and Francesco Fariello developed in 1939 for the *Piazza Imperiale* for the *Esposizione 42*.

Piacentini's gymnasium

The professional relationship between Saverio Muratori and Ludovico Quaroni had never been the subject of detailed study before the recent essay by Lucio Barbera – who was an ‘eye-witness’, as pupil of both of them at different times and in different ways – entitled *Quaroni-Muratori between dialogue and silence*¹⁴². Barbera’s study was encouraged (one might say commissioned) by the organising committee of the Convention of Studies on Saverio Muratori of 2011 recently published¹⁴³, and was presented in its first draft during this itinerant convention on Muratori in May 2011. What follows are the issues that emerge from Lucio Valerio Barbera’s study that are relevant to our purposes in this paper. First of all, the joint experience in the 1930’s of the youthful studies shared between Saverio Muratori, Ludovico Quaroni and Francesco Fariello, classmates in a faculty dominated by Marcello Piacentini. Barbera reports a rather difficult confession made by Quaroni: “between ’37 and ’40 they called us “the Dauphins”. Barbera reckons that this ‘ironically regal’ title was, on the one hand, due to Quaroni’s presence in the group, and ‘his never-mentioned though well-known Piacentinian “ascendance” had made him, in the eyes of many, the principal heir to a formidable professional and political position. Yet that nickname used in the plural – “the Dauphins” – revealed that there had been, perhaps, a shift in its meaning; the three were not simply the “Dauphin’s group”, but each stood out and distinguished himself for some recognisable individual quality – they were only twenty-six or twenty-seven at the time. I am certain that the young Muratori, with his capacity, or better yet his absolute necessity to make each act of design the consequence of lofty philosophical principles, undoubtedly stood out as a singular young individual with a tendency toward the theorisation of architectural composition”¹⁴⁴.

The Muratori-Quaroni-Fariello group, then, developed a series of projects for competitions, among the most important of which were the design for the *Aprilia Plan* already mentioned, the competition for the *Preture unificate* (1936), the *Opera Nazionale Combattenti* (1936) and the *Piazza Imperiale* project for EUR (1938). The detailed list of the competitions and works can be found in the section *Regesto delle Opere* in Pippo Ciorra’s book on Quaroni.¹⁴⁵

It was a period of real communal training; Barbera continues in his essay, trying to find useful clues to the ‘singularity and diversity’ of the two architects: ‘They constructed a very exclusive “time and space of self-education” [...] that generated lines of research that each would pursue in his own right over time [...] Despite the scale of the distance and growing mutual rivalry that developed over the years, we must not forget that in cultural terms they were linked by a common root and by a number of shared underlying convictions. These latter included the conviction that Rationalism, often in its German incarnation, served as an extraordinary demonstration, with touches of elegance, of the necessity of overcoming *the crisis of a determinate moment in a determinant space*. Making it a universal language meant making it a “style” among others, though it was intellectually comfortable and very economical to build. The post-war birth of the so-called “International Style”, in Italy loaded with political meaning – rationalism as the “style” of democracy – appeared to support their claims. Their point of view was derived from an even more profound conviction: that history is a continuum in which fractures and dramas can be overcome only if, beginning precisely with them, we start out once again with a greater understanding of the city in history, calling on all that we identify in it as significant values, processes and forms to model the city of the future. As part of this vision, at a certain point Quaroni and Muratori, so young at the time, appeared to confront also the problem of technology, in order to test the possibility that their vision could synthesise it, utilising in

favour of the modern city less its incomparable productive efficiency as the new idea of beauty that accompanied it.¹⁴⁶

The urban culture of Europe in that period reached the young Quaroni and Muratori through the filter of Piacentini's view of it; he used to teach wonderful lessons on European cities furnished by photos – his book, *Architettura d'Oggi* is an example – and up-to-date maps, but above all backed up by his incomparable direct knowledge (for his day) of the cities of Europe. Even when he became a professor emeritus in the fifties, Piacentini was still giving introductory lessons on the historical design and the form of European capital cities and their architecture (*Edilizia Cittadina*, town building, was the term he used) almost as if such didactic exercises were the lifeblood of his cultural outlook and of that of future Roman architects.. Piacentini was of the opinion that cities were the expression, and at the same time the *bedrock of culture* and the laboratory, of the development of architecture; modern architectural research derived its strength and its sense from the historical character of cities, as had always been the case throughout history.

Let us look at what he wrote in his book *Architettura d'Oggi*¹⁴⁷ in 1930 regarding European and Italian architecture, particularly the Roman variety: “Modernism in Italy became bogged down in simplifying theories, without taking the plunge. Rationalist and ultra-modern formulas are only now beginning to interest some of the younger architects, especially in northern Italy, but these ideas have an imported feel to them, and cannot yet be adapted to our particular climate. Our form of modernism instead is reattached to the entire evolution of Italian architecture and reflects the character and traditions of our regions. *Among the Romans, as is only natural, a broad sense of solemnity predominates*; for the Milanese, a greater reserve, a finer circumspection. *The Romans remain in touch, in a very free fashion, with ancient architecture, taking their inspiration from the ruins of the Empire, and reconnecting with sixteenth century art, with its wide surfaces, heavy protuberances and splendid profiles. Nor is there always an order to these massive forms. Their tutelary deity is Sangallo* (author's italics)”.

Baroque Rome, neo-realist Italy

Piacentini's words reinforce the idea that in that period there was in Rome a widespread and specific method of envisaging the form and the architecture of the city, rooted in history in its materials and appearance; but Rome was no exception. Piacentini maintained that the different European cities, regarded as primarily ‘cultural areas’ or a significant variation of such, were each characterised by a specific way of organising space and creating architecture that derived from a stable evolutionary process, taken up by and strengthened by becoming the dominant mindset of the local ruling classes, and in the case of capital cities, the national ruling class. This was a way of conceiving and organising the city that was to be respected or renewed or even invigorated by modernity, as Saverio Muratori would say at a later date. One certainly cannot hide the fact that for Piacentini, the elements of architecture (building materials present on site, climate, housing styles, social culture, relationship with natural and planned (urban designed) morphologies) were only vaguely and misleadingly defined as ‘spiritual identities’ of the local culture, or even merely as ‘Italian’, and other similar convoluted simplifications. However these few lines, where Piacentini traces a chain of natural evolution and reproduction from the remains of ancient Roman architecture through the early and late Renaissance to the threshold of the Baroque, describe the material and cultural (or ‘spiritual’, if we include all his categories) landscapes on which the main ‘Roman’ exponents of the Baroque era modelled themselves, and on which, therefore, the major exponents of modern Rome should continue to model themselves, in their own way. We should bear in mind that Piacentini was born at the end of the nineteenth century, and for him, the Rome of the popes, which commissioned and created much

¹⁴⁶ Barbera L.V. (2014) op. cit., 228

¹⁴⁷ Piacentini M. (1930), *Architettura d'Oggi*. Re-print 2009, Mario Pisani (ed) (Libria, Melfi), 36

of the Mannerist and Baroque architecture of the city, had lasted until just a few years before his birth. The exedras, both large and small, of the temples, the villas and the ruins of the baths that emerged from the landscape of the *horti urbani*, the idea of axial roads, tridents, symmetrical squares or squares with dynamic central spaces, ellipses, the idea of lines converging on an actual or virtual centre point or points – all these, originating in Rome, had certainly had an effect on most of the greater or lesser capital cities of Europe and had become the most lasting and recognisable components of western city culture. For Piacentini they had to continue to be a point of reference and an inspiration for the new generations of Italian architects, the precious grounding of modernity. This was the basis of his teaching, and Quaroni and Muratori, in the accustomed fateful dissension between master and pupils, reacted against it but also absorbed it while trying to supersede it with their own new youthful ideas. Each of them, in attempting to reject Piacentini's teaching, chose two different paths that led to the same end: the repudiation of rationalist and internationalist orthodoxy. Setting aside here the problems that they themselves would have seen as problems 'of style' rather than 'of architecture', in the post-war years, their interest in urban design pointed them towards the world of small Italian towns, situated in the arduous morphology of the Apennines, beset as they were with economic difficulties from ancient times. For each of our architects, this interest came about in different ways¹⁴⁸. Briefly, for Muratori, concentrating on these valuable places that seemed to best exemplify the strength, rationality and overall organic nature of 'natural' architectural processes, created an opportunity and a field for analytical research into the 'true state' of humanity within nature. For Quaroni, on the other hand, the same truth was to be learned through intuitive impressions, through the power of suggestion, by means of an ability to identify with and creatively reproduce the wealth of an urban and environmental complexity that no analytical or systematic process could ever replace. Here we should take a quick look at Quaroni's deeply felt belief about the value of intuition as a major tool for understanding and modifying reality. He used to say to his students (who sometimes would have preferred a more systematic or rationally organised form of teaching) that intuition was a form of reasoning of a higher order, a granule without size that contained the entire complex repository of our cognitive processes, which, if expressed in linear fashion or even in the most intricate of three-dimensional frameworks, demonstrate the transience and insufficiency of all reductive simplifications. And so, in the very years in which Muratori was starting to build his monumental system of 'scientific' interpretation of the relation between man and nature, in other words, of architecture, Quaroni resurrected the expressionist intuition of Bruno Taut, publishing for the first time in Italian his *Die Stadtkrone*¹⁴⁹, the City Crown, with a marvellous introduction, which I advise everyone to re-read.

Quaroni and Muratori

But at the end of these journeys of research that were so different, the arrival points as regards design seem to me, living two generations after the two architects' confrontation, to converge on one another to the point where they overlap in certain of their basic premises; I would say that they appear to coincide 'even more strikingly' if I consider those who have made each one of our architects the founder-figure of their own monolithic 'party', totally closed off to outsiders. On the other hand, for both Quaroni and Muratori, the spark that lit their independent research came from the short-lived yet intense enthusiasm of Italian neo-realism that almost unanimously assailed the thinking and aroused the interest of educated, professional, artistic youngsters who emerged after the second world war. For both of them, this experience, after initial experimentation, proved to be inadequate, and so, without changing the focus of their attention (the connection between building and organism, between the individual and society, and

¹⁴⁸ Cfr. Barbera L.V. (2014) op. cit., 219

¹⁴⁹ Taut B. (1919), *Die Stadtkrone*, (Eugen Diederichs)

therefore between an inhabitant and the urban space he inhabits), they moved from the poetry of the small ancient towns, which they saw as models for the new residential neighbourhoods to be built on the city outskirts, towards the search for an overall picture of the city, seen as a physical, and above all conceptual, place with a continuity of settled spaces and the co-presence of many-sided and contradictory (or also complementary) aspirations belonging to a complex society. During the same period that Quaroni, after his designs for the Tiburtino IV residential quarter, wrote his famous article criticising architectural neo-realism entitled *Il Paese dei Barocchi*¹⁵⁰, Muratori began revising his own design methods that he had adopted immediately after the war which were in part neo-realistic and in part rationalistic, moving on from his work in Rome on the INA Casa quarter at the end of the 1940's to the Naples and Magliana designs of the early 1950's. And here there unexpectedly appeared what Piacentini had perfunctorily prophesied, the 'genetic' teaching of Rome's urban architecture, which materialised in the atmosphere of antiquity, I would say of history, that typified the researches of Muratori and Quaroni, and which was certainly reinforced by their intuitive analysis of unplanned settlements in Italy, but also and directly by an exquisitely morphological examination of the 'compositional' efficiency at any given scale of the baroque urban and scenic system. Thus it is not difficult to see the 'genetic' origins of the great spoke-shaped radial systems that are a feature of the residential zones of Muratori's Loggetta and Magliana and of Quaroni's designs for the Barene San Giuliano and the Casilino district. In the first of these Quaroni designed a polycentric system of convergences which is monumental and semi-hidden at the same time, while in the Casilino project he dogmatically designed all the fabric according to polycentric convergences towards focus points that were by this time merely virtual; this marked Quaroni's elimination of any symbolic effect inherent in urban systems since he no longer believed that there was any remaining possibility of there still being a 'Crown' of the District. Instead Muratori still seemed to believe it in his Loggetta project in Naples, but this was no longer the case for the Magliana or the designs for the Barene di San Giuliano, where his research is entirely morphological and the monumentality that is indispensable in an urban context is exclusively assigned to the layout of the residential buildings themselves. It therefore seems to shed light on Muratori's remark in the academic year 1959-60, when he was commenting to his students on the results of the open competition for the Barene di San Giuliano, which he had won, that the only project that he found interesting (apart from his own, naturally) among all the designs presented by the elite of Italian architects of the day, was that of Ludovico Quaroni. A project, however, Muratori pointed out, that had been dealt with in a 'formalistic' manner; his use of this word revealed the difference between the two approaches, his and Quaroni's. Muratori certainly realised that his words were in any case an important tribute to Quaroni, but he could never have known then that he was proving Pippo Ciorra right, when, many years later, in the book mentioned above, he revealed that in the Barene project Quaroni was attempting to uphold "form as the primary instrument of urban design", to the astonishment of the Italian architectural world, and that he was opening "an explicit dialogue with the urban proposals put forward by the great modern masters". But Quaroni also, Ciorra goes on to say, appeared to want to restore meaning (if somewhat abstrusely) to the long-term aims that linked him to Saverio Muratori from an early age. Muratori's designs for San Giuliano, Ciorra says, were "the exact opposite in every sense to Quaroni's, yet this 'opposing polarity' – and here Ciorra is quoting Quaroni – 'resulted in a confirmation, rather than a contradiction of certain affinities that I shared with Muratori in the pre-war infantile period of architecture'". Finally, reflecting on the courses in composition during his teaching experience at the Rome School of Architecture, Quaroni wrote¹⁵¹ some significant comments on Muratori in the cultural atmosphere of the Faculty of Architecture in Rome: "after the twenties, which were a sort of decade of trial runs, came the thirties and the crisis of rationalism, the controversy of 'the arches and the columns' and the famous struggle between modernity and tradition (the review

¹⁵⁰ Quaroni L. (1957), *Il paese dei barocchi*, in (Casabella-Continuità, Milano), n.215

¹⁵¹ Quaroni L. (1972), *Cronaca d'un corso di composizione*, (Controspazio, Roma), maggio-giugno, n.7

Casabella was forbidden to students and the Library did not subscribe to it); then we had the forties and the war, then the 1950's and the neo-realist crisis, the organic movement and the APAO which flowed into the student movements, a battle that pivoted round the *old* and the *new*, that was principally a movement of an élite that was aware and culturally and politically committed, up against an élite that was conservative, culturally represented by Muratori alone, but exploited politically by a group that had more or less disqualified itself by the bad behaviour of its followers and disciples. Muratori's philosophical standpoint was totally different from that of the Italian Academy who wanted the Faculty to be a 'breeding ground' for small-time professionals armed with tracing paper. It was Muratori who first began to read books on architecture and get his students to read them; the first, in Composition, to teach on a cultural plane and get to work on a disciplined plane. He was also one of the first to specialise in city architecture [.....] But the discipline Muratori insisted on did not work for our times, and despite the fascination of his words, many students said they were dissatisfied with his teaching". At this point Quaroni's voice seems full of consideration and regret, a voice speaking the truth about his 'true' Muratori, his companion in 'the pre-war infantile period of architecture', but also a difficult, fragile friend; there was much that linked the two of them, and much that separated them; there was much that he learned from him, and much that he rejected. In the last years of his life Quaroni loved to listen to the music of Brahms, with whom one can imagine he loved to secretly identify himself; he saw himself in the loneliness of the German composer, who was only half understood in his day, and also perhaps, in the pointless, condescending story about the great rivalry between Brahms and Wagner and the Wagnerians, invented, as always, by the 'best' disciples of one or the other.

Project descriptions and figures

The geometric arrangement of the 'La Loggetta' (up) project in Naples has many similarities to the Casilino project: it has a radial network system, but compared to the Roman project it is situated on a hill rather than on flat ground. This has influenced the creation of a landscape¹⁵² which has as its focal point the service area and the church which are clearly shown in the perspective view of the project. This view brings to mind the designs for the village of La Martella Village by Ludovico Quaroni (down), built with a completely different rationale in an area that is mostly flat and only slightly sloping, and which determines the scenic appearance of the buildings that surround the 'crown of the city', the church, with the rich variety of residential buildings below (La Martella Photo). The height of the buildings in the La Loggetta project, on the other hand, is constant, and the variations in shape are made by varying the heights of the plots on the sides of the hill. Reproduced from Maretto M. *op. cit* (La Loggetta) and Ciorra P. *op.cit.* (La Martella).

Muratori created four designs for the Magliana project (Magliana I on the left, Magliana II on the right), one for a settlement at the foot of the valley, and the other three for a settlement arranged on a complex hill ridge. All of them remained in a somewhat preliminary state, especially those for the ridge. The most complete was the one for the valley, and shows a considerable evolution from the INA-Casa La Loggetta project from a few years before. The designs for the hill ridge are masterful compositional exercises in a very difficult natural morphological situation using the most refined instruments from the baroque urban project in which, under extreme conditions, Muratori experimented with his already elaborate system of analysing and designing the city: external and internal polarities, architectural piazzas, and axial and radial roads worked out, naturally, by his very advanced studies of the hill ridge settlements. Reproduced from Maretto M. *op. cit* (Magliana I-II)

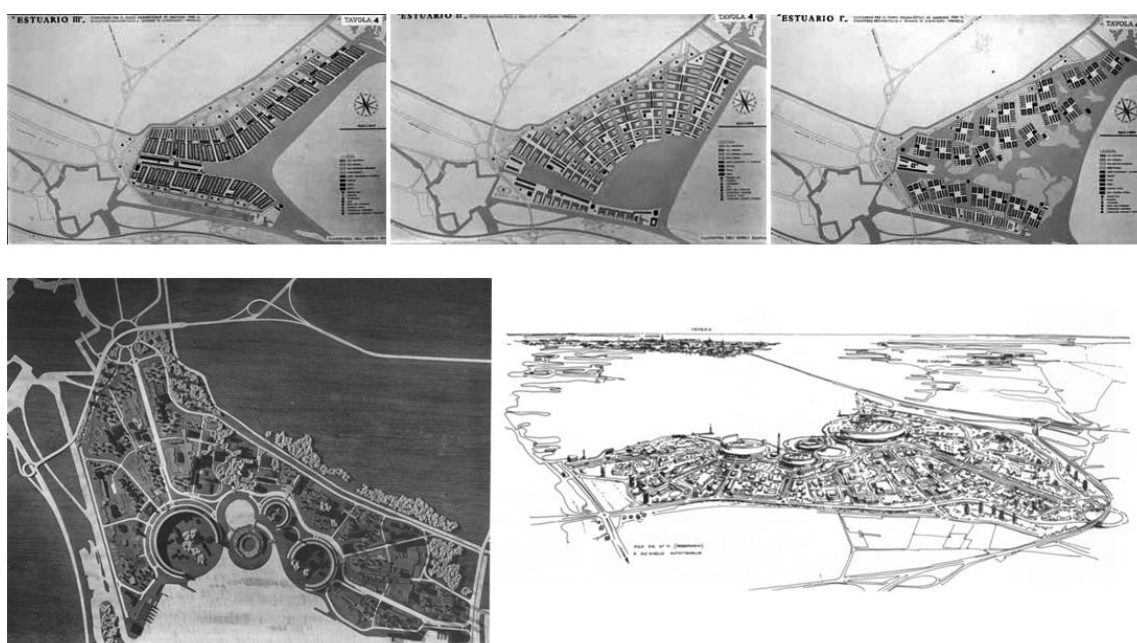

Figure 4. Le Barene di San Giuliano (1959): centre and radial system.

The projects developed by Muratori and Quaroni for the Barene di San Giuliano are too well known, analysed and published for me to make a detailed description here. I shall merely draw attention to certain characteristics that are relevant to our present purposes in this short paper. Both architects made the presence of the city of Venice on the horizon of the lagoon the focal point of their designs. These designs therefore were arranged according to a radial layout, more or less expressed in the overall plan. The interrelation with the water was determined in different ways by the two architects; Quaroni used a language that was decisively geometric, abstract and expressive, while Muratori saw the logic of the inescapable morphology of the sea front with respect to the urban fabric, and he could not avoid, for example in his winning design, a reference to the baroque and late-baroque palace complexes of the cities on the Tyrrhenian sea and the attempt to restore the apartment blocks of Giuseppe Samonà in Messina. In Muratori's designs for the Barene, the *centre* as a physical place is an identifiable area and forms part of the design. Quaroni's designs, on the other hand, did not have an well-identified functional centre, while there was a central zone of great modern monumentality which however seemed to be mostly residential. This was set in a geometric radial system, whose rhythmic force was interrupted dynamically by great circles of varying size, which were where the entire design converged; behind was an area developed in an apparently free style, like a Kasbah, wrote Ciorra, 'a series of types of the modern: a residential fabric with courts, in clusters, in lines, uniting together in a new mode the typology and the form of the city. The form and size of all the buildings, in fact "essentially depend on their function within the general form and concept of the quarter"¹⁵³. Yet even in Quaroni's design the real centre of the fan-shaped composition is the view of Venice that emerges delicately across the waters of the lagoon. The sense one has of large buildings in the form of cylinders open to the landscape is therefore one of great *mirrors*, *reflecting* the geometric centrality of the residential district within the landscape of Venice at the centre of its inland sea. Figure 5. Casilino (1964): the opposite of the Barene of Quaroni, the similarity to the Barene of Muratori.

¹⁵³ Ciorra (1989), *op.cit.*, 46

An important commentary on the questions we have been discussing here, and in particular, on the Casilino 23 project, is made by Roberto Maestro in his recent essay on Quaroni's Casilino project, in which he took part as a young and active assistant: 'How do you arrive at that solution? At first sight we thought of using the model of the geometry of Roman piazzas (based on circles and ellipses) but we scrapped that idea because it would lead to a solution that was closed, not really suitable for the design of a city neighbourhood in expansion. And then that solution was too 'Quaronian', or rather too formulaic for Quaroni himself. Lucio Barbera recalls that he used to tell Quaroni that the Casilino 23 project seemed to follow along the same path as Muratori's researches for the Magliana quarter, and so also some of his designs for the Barene. Barbera noted however that Quaroni's Casilino 23 designs appeared to be the reverse of his designs for the Barene. On the same radial layout at the Barene, Quaroni envisaged the powerful architectural presence of the polycentric arrangement that supported the fan shape of the convergence of the fabric, whereas at Casilino the centres of the convergence disappeared into an indefinite space that was partly green, partly and irregularly covered, while the rays of the fan emerged stereo-metrically as the main features of the urban form. Roberto Maestro, another pupil of Quaroni, adds: 'in the Casilino project you can quite easily see that Quaroni's idea was to reproduce, on an experimental scale, that mixture of freedom and restriction (or rules) that formed the basis of the medieval city, and thus prove the effectiveness of the traditional tools of architectural design on the formal management of a modern city of today.'¹⁵⁴ Reproduced from De Sola M. Re-thinking city. An example of Ilse's multidisciplinary approach to urban morphology questions

Corinna Nicosia

DASTU – Dipartimento Architettura e Studi Urbani, Politecnico di Milano.

E-mail: corinnanicosia@gmail.com.

Abstract. *«Architettura della città» written by Aldo Rossi (1966) is a classic in urban morphology, but we must look at this book in its original form, a field research report (1964), in order to understand how much urban morphology is important in the city planning design process. Analysing the report we can point out the main references on which Rossi bases his new urban science theory, also we can trace the basis concepts that Rossi will develop in the book written two years later. Reading the report within its original wider context, the Ilse's scientific program – a program shared by politicians, administrators, technicians and academicians – means contextualize the Rossi's thought in the Italian Sixties debate, a reformism season where territorial management could not regardless reasoning about city, its form and its content. In this sense, the Rossi's theory goes back to being part of the urban planning debate in line with one of the two new territorial imagines discussed.*

Key Words: Ilse's, Aldo Rossi, urban questions, urban planning.

The urban question in the Italian sixties debate

The Sixties were the most fertile period for Italian urban planning: the economic boom, the reconstruction of bombed-out city, the large-scale migration and immigration movements and the rapid urbanization of increasingly large portions of territory posed a number of new technical and theoretical problems. The 'urban question' becomes part of the public language: State becomes a promoter of development and, therefore, demands to local governments a qualitatively and quantitatively improvement of their action. New situation make it clear that studying in depth the socio-economic aspects of territory has become a necessity (Bellaviti and Fareri 1986, p.3, p.43).

To cope with these new demands, some public and private research institutes were established. These ones – as well as providing support to the government – thanks to the introduction of social sciences, help to update the techniques, methods and tools of all those disciplines that have city and territory as their object of study (Romano 1980, p.127).

At the same time, the urban question animates the town planning-architectural debate raising numerous objections to the disciplinary tradition that, according to some critics, was not able to deal with the new territorial transformation dynamics. Especially planners, who still had not been able to formalize a scientific statute for their discipline, trying to legitimate their technical knowledge by developing a new cognitive model (Olmo 1992, p.X; Romano 1980, p.80).

A strange relationship between politicians and technicians was created: politicians see technicians as the modernizing force that is essential for the development and, therefore, they seek a technical advice to justify their political choices; technicians need the support of political power to give authoritativeness to their intervention (Crosta, Pizzorno and Secchi 2013, pp.11-12; Olmo 1992, pp.X-XI).

Milan, where a part of political forces had already begun a slow renewal process of the ruling class, becomes an excellent testing field where for the first time technicians work with politicians (Landoni 2011, p.107). The Institute for Economics and Social Studies of Lombardy (Ilse) established in Milan in 1960, is an illustrative case of this reformism season: representatives of the main political forces and the most important members of the academic

staff are involved; the scientific products, based on American socio-economic researches matrix, help to introduce social sciences in the Italian culture (Crosta, Pizzorno and Secchi 2013, pp.11-12).

The 'Metropolitan area urban structure' research group

Ilse's aim was twofold: to carry out socio-economic studies; to cope with the problems related to regional planning¹⁵⁵. The Institute tries to accomplish its task by putting together a team of experts from different disciplines (urban planning, sociology, economy, finance, etc.) to take an overall view of the complexity of territory.

The original work program was organized in nine projects research whose case study was the Milan metropolitan area. This was not just an object to be analysed – what are its structures? how can we steer the development? – but also a problem to be defined – how can we recognize the metropolitan area spatial extent? how can we trace characters of a metropolitan community?

The 'Metropolitan area urban structure', directed by Giancarlo De Carlo and Paolo Ceccarelli, is the most interesting research project. They carried out about eleven researches (1962-1965) through which they wanted to understand what were the factors, that interacting with each other, determined the structures and the morphological configurations of the Milan metropolitan region. Among these works, in 1964, was published the Aldo Rossi's research, «*Contributo al problema tra tipologia edilizia e morfologia urbana. Esame di un'area studio di Milano, con particolare attenzione alle tipologie edilizie prodotte da interventi privati*¹⁵⁶», on which he will base the book «*Architettura della città*» (1966).

Many of the conclusions outlined in this research group have also had wide repercussions outside the Institute: the famous *Turbina* plane (1963), made by Giancarlo De Carlo, Silvano Tintori and Alessandro Tutino, was based on the data and analyses carried out by Ilse's; the De Carlo's book «*Questioni di architettura e urbanistica*» (1964) was taken from results of numerous observations made by the Ilse's researchers and it tried to state a new way of reading and interpreting territory; the famous meeting «*La nuova dimensione della città. La città regione*¹⁵⁷», organized in Stresa (1962) by the De Carlo Ilse's research group, was one of the most important moments of the international debate.

The new dimension of urban phenomena forces architects and urban planners to redefine their branch of learning (Lobsinger 2006, pp.30-32). Rossi's opinion gradually moves away from the De Carlo's group statement and we can see the impact of these theories on the disciplinary debate looking at the two new spatial images produced: *città regione* and *città territorio*.

The report

Rossi shared the De Carlo's group starting hypothesis: there is a close relationship between planning goals and urban form, since each phase of planning process is crystallized in a specific pattern, but the targets choice, although based on multiple factors, depends largely by human behaviour. For this reason, enforcing a city in a form without regard these complex dynamics, would have serious implications both from an economic point of view – because there would be a resistance would rise the operation costs – and from a social point of view – because the

¹⁵⁵ Although Regions had already been included in the Constitution (1948) and the issues related to regional planning had already been dealt with in the Planning Law (1942), Regions were officially established in 1970.

¹⁵⁶ «*Contribution to the problem of building typology and urban morphology. Examination of a study area in Milan, with a focus on building types produced by private interventions*»

¹⁵⁷ «*The new dimension of the city. Città regione*»

operation would be rejected. The De Carlo's group was working on the theoretical references developed by F. Stuart Chapin, who correlated urban structure changes to the sequence of individuals and social groups behaviour, and those developed by Lynch and Rodwin, whom proposed an alternative analytical method to describe urban form and to extrapolate the traces of effects left in space organization by the activities localization.

In my opinion, Rossi takes two step forward: he explores the transformation of urban fabric in a transversal direction that can hold together times and modes of evolution (Rossi 1964, p.II); he shifts the focus of analysis from urban structure to the structure of architecture, because Rossi thinks that the changes in a minimum element of a system can trigger the mechanism of the whole structure.

Already in this first work, we can see the main features of the new urban science developed by Rossi in the following years. He proposes urban planning shifts towards architecture, where architecture becomes the tools through which know the reality: on the one hand, architecture allows us to study the structures and dynamics of the city process formation; on the other hand, through architecture we can develop new tools and methods for planning (Vasumi Roveri 2010, pp.26-30; Lobsinger 2006, pp.28-29).

It is no coincidence that Rossi develops this new ideas within Ilse: on this occasion Rossi comes into contact with social sciences that widen his literary knowledge and help him to 'rediscover' some classics (Vasumi Roveri 2010, pp.32-54).

An urban morphology study, in the context of this reformism season, is relevant: who have to deal with urban morphology becomes an interlocutor for who dictate terms of the public agenda because urban morphology specialists view city from a different angle, since urban fabric is no longer considered as a product of time but as a product of society. This turnaround appears in the Rossi's work especially in the choice of references on which he builds the reasoning.

Object of Rossi's research is a wedge-shaped area that extends from the center of Milano to the periphery¹⁵⁸. The result that this research wants to reach is the identification of the interrelationships between urban form – in terms of the relationship between building typology and infrastructure – and social structure. The aim is twofold: using the data obtained from survey to express an opinion about the characteristics of urban fabric; formulating hypothesis about the structure-form ratio, referring both to the present situation and the evolution in progress (Rossi 1964, p.I).

The report is organized into three sections: the introduction, where the author exposes the underlying assumptions and describes the methodological approach; the first part is divided into four chapters, which collect the cartographic documents and surveys; the second part is divided into nine points or paragraphs, where Rossi argues investigation findings. The iconographic equipment is composed by maps and technical drawings that attend and illustrate the analysis. One interesting thing is that this section has its own bibliography. The bibliographic notes conclude the report and are a programmatic selection. Looking at the bibliographic references, explicit and implicit, we can understand the Rossi's attempt to reformulate the problem of urban form within a wider design reflection, although initially Rossi seems to abstract its reflection compared to the contemporary debate on the different governance dimension (Vasumi Roveri 2010, pp.28-29). Four books are essential: «The City», written by Robert E. Park, Ernest W. Burgess, Roderick D. McKenzie (1925); «*Introduction à l'urbanisme. L'évolution des villes*», written by Marcel Poëte (1929); «*Le mémoire collective*» written by Maurece Halbwachs (1950); «*Géographie des villes*» written by Pierre Lavedan (1936).

Revising them, Rossi extends the meaning of urban morphology from a simple analytic tool to a guide for planners.

¹⁵⁸ From Piazza Mazzini to Viale Beatrice d'Este; from Corso Italia to Corso di Porta Romana

Study area, urban space construction, *fatti urbani*

The definition of the study area is not a simple problem of selection, but it is a very important theoretical point. Rossi refers to the concept of natural area¹⁵⁹: is a city portion that, during the urban structure evolution, develops its own characteristics because of different growth processes. This allows us to distinguish it among other areas. This means that, if it is possible starting from the analysis of these characteristics, through historical recognition, to reconstruct the area evolutionary process, it is also true that the identification of these dominant features allows us to work out future trends (Rossi 1964, p.105). Rossi starts from the assumption that city is built up over time, therefore, on one hand, as citizens we can experience just a few moments of its history, on the other – both from the architect and the urban planner point of view – city maintains the memory of what it has been and it holds traces of what it could be.

Another important aspect is the interdependence between area and its inhabitants: environment is continually shaped by individuals and social groups behaviour, understood as common values and ideals inherited from a particular culture; environment affects these behaviours through primary impulses of urban life, such as economic and social needs and desires. Spatial grouping forms, therefore, may be constant or they can change over time. This depends on the importance of behaviour patterns, since they cyclically affect the spatial forms reappearing, determining frequency and permanence over time. This spontaneous zoning trend was also empirically demonstrated by the early sociology and ecology studies applied in the urban field.

The main contributions about the sociology aspects of urban life came from the surveys realized by the Chicago School of Human Ecology (1920-1970). The first collection of essays is «The City», published (1925) by Ernest W. Burgess, Roderick D. McKenzie and Robert E. Park.

This book is relevant for some key concepts that have opened up the way for new studies. One of these concepts is 'natural area', proposed by Park to indicate the people tendency to congregate according to homogeneous characteristics. From the human ecology point of view this process can be explained by distinguishing between two basic relationship types: social selection and division of labour; agreement and assimilation (Torres [1996] 2000, pp.217-218). Evolutionary process can be summarized, therefore, in two main phases, invasion and succession – taking these concepts from natural ecology – that indicate penetration and slipping of a group in an area that is already occupied by a different entity. We can understand how social mobility becomes synonymous of spatial mobility. Contrary to what we may think, the area still retains a leading role, because it develops its own character – let me say – its own consciousness, which allows it to react to invasion in a positive way, attracting them, or in a negative one, rejecting them (Elia 1971, pp.31-32).

What is natural to assume, therefore, is that this process occurs regardless of planners' projects, because it takes life by energy that – as in the osmosis processes – is generated when social organization and physics organization interact. Understanding city development as a 'process' is another original and important aspects dealt in this book: Burgess uses 'metabolism' to describe this continuous process of organization and disorganization of society that leads to the renewal of urban organism (Park, Burgess, McKenzie [1925] 1967, p.7, pp.52-53; Elia 1971, pp.31-32).

The biunique relationship existing between environment and people, in terms of mutual transformation, has already been recognized, but Rossi wants to emphasize that there is a further degree of complexity expressed in the consciousness of social body in relation to the places it occupies. Social morphology studies, developed in France in the late Nineteenth and early Twentieth century, had faced the problem of social body 'form', that is how society is spatially determined within urban structure, describing the practices and their effects from the social point of view, and how its structure evolves over time. A breakthrough is made when

¹⁵⁹ Rossi uses the English word in the report

Halbwachs analyses through what kind of *immaginario* the different entities – that make up the social body – become aware of it (Jedlowski 1987, pp.13-14).

We must look to the Halbwachs' book « *Le mémoire collective* », in order to understand how the thought of the French sociologist and philosopher influenced Rossi. Halbwachs wanted to investigate and examine the relationship that memory, here understood in the particular meaning of collective memory, interweaves with the various dimensions of reality (Halbwachs [1968] 1987, p. 137).

Signs and images that are gradually deposited on the elements of the city express the dialectical relationship existing between environment and inhabitants. This slow sedimentation process means recognizing a value in certain areas or in certain buildings that goes beyond their formal or aesthetic qualities. At the same time, however, this accumulation process turns out to be a strict selection process: we can perceive only the strong and distinctive characters that remain over time, ultimately, those which contribute to form the image of the city. In this sense, the memory becomes the instrument through which we – as citizens – take position into its construction process. Contrary to what we might think, our contribution, since it is strictly temporally defined, is still active and constructive, because the tool we use – memory – is a tool for a critical selection: it does not make us able to revive the past, but through memory we can remodel some aspects of the past in response to the needs solicited by our present conditions (Jedlowski 1987, pp.20-21).

Thinking city as the deposit of the community experience signs, reminds me of what Roland Barthes said about urban semiology. Urban space, understood in a strictly material sense, has always been a mediator of meaning, and as such it is comparable to a linguistic sign. Therefore, urban space can be broken up into form – the combination rule that organizes concepts – and substance – the material articulation of the concept. Understanding city as the expression of a concept through a material mediation, but mainly as a linguistic sign, means reading it by forms and substances whose physical traces can be taken up and manipulated. These signs whereas are irreversible because they are a container for the transmission of the social institution values, therefore they can not be changed by individual, but only by community. Introducing the concept of space as a sociological category, Halbwachs considers the memory as an institution. Urban space and its elements become the forms through which the memory explicits itself.

Obsolescence and decay become synonymous of continuity. The slow aging of certain parts of the fabric, due to the progressive loss of efficiency and functionality, is interpreted as a loss of value and it shows those parts of building fabric that are prone to accommodate recovery or expansion. At the same time, however, the presence of these parts shows that, regardless of evolutionary process that involves the whole urban system, some items – houses, streets or neighbourhoods – survive the natural selection. These *isole* or *aree di riserva*, as Rossi defined it (Rossi 1964, p.110), can become strategic elements because they are the result of almost spontaneous micro-dynamics, which express the right and natural city evolution process.

If evolution of urban structure is not governed by a top-down action, it must exist an implicit design that directs development. Rossi, referring to the Pierre Lavedan's studies, talks about the 'implicit plan' as a set of city elements that create an invisible but solid frame on which city grows. «*Qu'il s'agisse d'une ville spontanée ou d'une ville créée, le tracé de son plan, le dessin de ses rues notamment, n'est pas dû au hasard. [...] Il existe toujours un élément générateur du plan*» (Lavedan [1936] 1959, pp.91-92).

Lavedan introduces and develops the concept of 'plan' as that forces system which, forcing on some foundation elements, determines the shapes of urban structure evolution. Through History, we can see how human laws have gradually replaced the laws that had always governed city development. In certain cases it is complicated finding the *élément générateur* of these forces, especially if the city is ancient, and is also impossible to think that there can be only one generating element (Lavedan [1936] 1959, p.18, pp.92-94). The «*comprensione e creazione*» (Rossi 1966, p. 142) process through strategic elements, as Rossi said, joins the past city to the future city. This is the right way to accompany urban system evolution in accordance with his implicit plan.

Lavedan rightly states those generating elements can be either *matériels* and *intellectuels*, Rossi often uses the expression *âme de la cité* to give us the idea and make us feel the consistency of this aspect that is intangible and indescribable with the terms of reason, but all of us daily experience it as citizens. The preeminence or individuality – to use a Rossi's word – of these elements, therefore the justification for their active role within urban system, is due to their ability to catalyse forces. Rossi uses *fatto urbano* locution to indicate these urban elements: the word *fatto* takes us back to the real and physic dimension of what we experience as inhabitants of a place; while its nuances of meaning – action, event, etc. – can make us feel the exceptionality dimension of that experience. This locution comes from the French urban geography knowledge and we can find it especially in the Pierre Lavedan and Marcel Poëte studies.

Rossi referred to Poëte theory, when he says city is an organism. This means not only that who want to design city have to deal with past, but it also means that city is a living entity. Continuity of life is manifested by the presence of some significant elements – roads and buildings – that come from distant eras and characterizes city as a whole and also they infiltrate into its minimum elements. Reconstructing the story of a particular building we can see that it is constantly in evolution, although it seems fixed in a precise form. Poëte suggests a evolutionary approach to the study of city: as in the case of human organism, evolutionary process selects only those characters that have been able to adapt to change. From the urban planner point of view, therefore, it will be crucial examining how some urban structure elements have been evolving naturally to adapt itself to the needs dictated by time, rather, this study should become the guide for planning actions (Poëte [1929] 1958, p. 25, pp. 128-129, p. 132).

City structure, in other words, varies over time, it maintains some fixed elements that constitute its load-bearing structure. They are active elements compared to the city growth dynamics, because they are the centers around which – and through which – city continuously reorganizes itself. These elements are permanence in real and physical terms, «*un passato che sperimentiamo ancora*» (Rossi 1966, p. 51), but they are persistences from a 'qualitative' point of view, because of their intrinsic qualities which distinguish them in the system.

Their function or their form does not determine the exceptional nature of these elements, although in most cases their trace constitutes an exception within urban fabric. Speaking of the exceptional qualities of these elements, we immediately think of monuments (Rossi 1966, p. 24): 'monument' is a status that we confer to an element in reference to the community imagination.

Città regione vs città territorio

If city grows without the aid of a plan, what is the urban planning role? «*D'altro canto il concepire la fondazione della città per elementi primari è a mio avviso anche l'unica legge razionale possibile; cioè l'unica estrazione di un principio logico nella città per continuarla*» (Rossi 1966, p. 143).

The city that Rossi imagines is a city of cities, where each fragment evolves as a result of both direct transformations – which depend on factors within the area – and reflected transformations – whose causes stem from dynamics originated in other portions of the city (Rossi 1964, p. 6). According to this logic, using the plan as a tool would be contradictory: we can not think of applying a unique design on different reality. In most cases, in fact, the plan does not have a positive effect on city structure, rather it isolates *fatti urbani* and it contrasts its action (Rossi 1966, p. 133). If we accepted the idea of a city made by fragments, we should work focusing on primary elements in order to take advantage of them as growth engines.

Although initially Rossi seems to abstract its reflection compared to the contemporary debate on the different governance dimension, this statement shows us how his thinking is in line with one of the two hypothesis that, in those years, animated the disciplinary debates.

The De Carlo's research group was processing a new territorial concept, *città regione*, that comes from the American 'city region'. They look at Geddes and Mumford theories and they refer to the line of research generated after the publication of the Robert E. Dickinson's book 'City, Region and Regionalism' (1947). *Città regione* is a constellation of remarkable points of the territory linked by continuous and dynamic relationships, in this way they share the same economic, social and urban development process (Aymonino 1964, p.94; Dickinson 1952, pp. 2-17). In this scenario, we can no longer talk about town as a generator center, but we can talk about the potential expressed by the different parts of the territory in order to capture or repel the forces that govern the location process of people and activities. Urban planning goal, therefore, is to identify systems and structures (Viganò 2010, p.215).

This concept is opposed to *città territorio* that is an own Italian locution, in fact, it appears for the first time in the workshop organized by Aymonino «*La città territorio. Un esperimento didattico sul Centro direzionale di Centocelle in Roma*¹⁶⁰» (1962), and in the essay «*La città territorio. Verso una nuova dimensione*¹⁶¹» (1962), written by Giorgio Piccinato, Vieri Quilici and Manfredo Tafuri. According to the authors, it was necessary using this neologism to emphasize the difference between American examples, where 'region' is an area whose size is variable, and the Italian situation, where the word *regione* referees to a specific political and administrative entity (Campos Venuti 1967, p. 62). *Città territorio* instead means a network formed by different cities. In this scenario, urban planning has to identify new themes and their interrelationship (Piccinato, Quilici, Tafuri 1962, pp.16-17).

An illustrative example of the latter statement can be found in the debate about *centro direzionale* and *asse attrezzato* in relation to historical center – which is well documented in the Casabella numbers published during Sixties. These two elements were the solution to remove directional functions from historical center, in order to protect it and to promote the localization of cultural activities (Aymonino 1964, p. 21). This issue has always been felt in Italy, but new size of urban phenomenon imposed a serious and critical meditation. Before the explosion of city in modern times, our territories had homogeneous characteristics, therefore, the ancient nuclei had to stand out as a place of interests and values. In a *città territorio* scenario, instead, the old center will have to find a synthesis with the whole territory in order to restore the balance necessary to survive. This means understanding *centri direzionali* as elements that mediate city and territory. They should be complementary respect historical fabric and they should work in synchrony with it. The lesson we can learn from historical centers is the ability to develop a continuous and compact fabric, where functional and formal uniformity also allows the formation of singular points or 'monuments' that are its backbone (Aymonino 1964, pp. 28-29). *Centri direzionali*, therefore, would have become the new generating element of *città territorio* (Aymonino 1964, p. 24). *Centri direzionali* and all the facilities for community life – universities, shopping centers, cultural centers, etc.. –, which are already spread in the contemporary territory, will become the monuments of the metropolitan area.

In opposition with *città regione*, they want to reflect again about city as a generator, but redefining the meaning for the word 'city' because it is no longer sufficient to describe the spatial, economic and social complexity of the urban organism (Lobsinger 2006, p.30). The reasoning about the shape of the city goes back to being central in the urban question debate: the many issues raised by urban phenomena can not be resolved through a single and general project, but the action should be focused on the design of little city fragment that can be strategic for the evolution of the whole organism (Viganò 2010, p.219).

We must read the Rossi's reasoning in this second line of thought, that aims to redefine the role of planning within the architecture field: urban planning goal is to provide a framework within which the urban fabric project can deal with the construction of urban space, as a place where society can build its image. Urban morphology, therefore, from an analytic tool becomes a design tool.

The influence of classics on contemporary thinking Louis Kahn and Hestnes Ferreira

Alexandra Saraiva

Faculdade de Arquitectura e Artes. Universidade Lusíada _ Porto; CITAD
Rua Dr. Lopo de Carvalho 4369-006 Porto, Portugal.
E-mail: saraivaalexandra@gmail.com

Abstract. *Architecture and the consequent urban form can be analysed and interpreted without reference to classical influences? Or can we analyse the urban form dated to the time and devoid of any previous bonding or influence? The purpose of this article is to show that two contemporary architects, Louis Kahn and Hestnes Ferreira created their own language of interpretation and implementation of formal relations at the same time they developed their buildings, transposing the formal urban analysis for the formal development of each projected unit. The designation of morphology results from the analysis of configuration and the exterior structure of an object, in direct relation to the phenomena that arise. Despite all the classical thought, the architecture of both architects closes a dimension beyond the essential nature of architecture as Michel Freitag uttered (2004) in his book *Architecture and Society*. The architecture relies on a phenomenological and sociological interpretation related then with *History of Architecture*, aiming to understand the urban form. Louis Kahn and Hestnes Ferreira approach the process and the materialization of urban form by following these guidelines. The main conclusion of this article is to prevent that architecture, in contemporary thought, do not continue to be associated with the paradox of the beautiful and the ugly.*

Key Words: Louis Kahn, Hestnes Ferreira, classic influence, contemporary thinking.

Introduction

Our reading and comprehension of architecture remain intertwined, with architecture history always supported in Art History tradition, oblivious of social analysis and social and historical identity. Therefore, it is almost impossible to analyse both the architecture and the urban form without comparing them to the classical models. Architecture, art, literature and philosophy history have always determined broad and deep domains.

Louis Kahn and Hestnes Ferreira's fascination with Architecture History and classical models knowledge were essential in their architecture. The purpose of this article is to demonstrate that these two contemporary architects have created their own language of interpretation and implementation of formal relations, simultaneously to the development of their buildings, transposing urban formal analysis to each projected unit's formal development.

The influence of the classical thinking on contemporary architecture

Our intention to map the classical thinking influence is centred on these two architects and how their architecture displays that influence.

Morphology is the result of both configuration analysis and outer structure of an object, in direct relation with the phenomena that originate it. Analysis fits in the sectorial dimension, just as Lamas (1993) refers the street scale, having the author also analysed the dimensions as presented by Rossi and Tricart.

The proposed formal analysis is based on the four aspects presented by Lamas (1993), the quantitative, the functional organization, the qualitative and the figurative ones.

Studies by Rudolf Arnheim, Kevin Lynch, Christian Norberg-Schulz, Francis Ching, Josep Maria Montaner, among many other authors, present different models of descriptive and phenomenological analysis of formal configuration.

In his book *A Modernidade Superada. Arquitetura, arte e pensamento do séc.XX*, Josep Maria Montaner (2001) refers to Louis Kahn as one of the architects from the third generation of the Modernist Movement, next to Denny Lasdun, Jorn Utzon, Aldo van Eyck, Josep António Coderch, Luis Barragán, Fernando Távora, and others. According to Montaner, all these architects assume a different attitude, they intend to incorporate history, to associate it with vernacular architecture, adjusted to reality and its user, thus rejecting both the formalism and mannerism of the international style.

Louis Kahn initiated his professional practice under the scope of the Modernist Movement, but evolved in a different direction from the 1950's on. Kahn didn't relate to the rupture propositions meanwhile adopted regarding the form and planning of the modern city.

Montaner (2013, 41) refers that,

... con un fuerte ascendente platónico, el pensamiento de Louis I. Kahn evidencia la influencia de Andrea Palladio, por su relación entre obra escrita y construida y por divinización de la idea, el orden y la simetría. Y una de sus más destacables aportaciones se refiere al concepto de nueva monumentalidad en arquitectura.

Although Louis Kahn never refers to Martin Heidegger or his *Carta sobre o Humanismo* (1949), Norberg-Schulz writes that he intends to find the projecting form reasons and their theories, in light of Heidegger's philosophy. The text is rather surprising, once that, just like Hestnes Ferreira does, it mentions that Louis Kahn did not reveal his source of inspiration, nor did he talk about his conception process. Hestnes Ferreira mentions in Saraiva (2011, 287),

Kahn não defendeu princípios que depois renegasse, havia sempre uma evolução, o pensamento dele flutuava, evoluía, assim como evoluía a arquitetura dele, criando novos conceitos e espaços. A coerência com que destacou nessa altura a importância da arquitetura moderna, dado o seu contributo para a renovação da arquitetura americana e para si próprio, nos anos trinta e quarenta, levou-o também mais tarde a ser dos primeiros a criticar a arquitetura moderna, nos anos cinquenta.

Ignasi de Solà-Morales states that ethical humanism and aesthetic phenomenology had their highest influence in 1950's architecture, presenting the reasons for that influence,

Realización personal, producción experimental, plena libertad estética, disolución de la tradición moderna como método racionalmente elaborado serán puntos de apoyo de un sinnúmero de obras arquitectónicas en las que la experiencia individual, la primacía de lo privado, el anti monumentalismo, la incorporación de materiales y técnicas antropológico-vernaculares, la búsqueda, en definitiva, de un grado cero para la arquitectura. (1991,33)

Although he wouldn't say it, Louis Kahn used Beaux-Arts notions, namely the central plan and the centrelines, even if only as starting points that would then be overcome by other factors. Hence the need to travel, to know, to register and understand the classical civilizations, having stayed in Europe for two long periods. This same need was confessed and felt by Hestnes Ferreira.

The sectorial dimension in works by Louis Kahn and Hestnes Ferreira

According to Kahn, the architectonic project process is divided in two distinctive stages that alternate throughout the process: the conceptual and the material stages. The process initiates from the production of a conceptual image that sets the basic principle around the project essence and to which all other generated elements are subordinate.

In terms of formal and conceptual process, there is continuity in Hestnes's process, when compared to Kahn's.

Design, order and form are understood as part of the formal development process, where geometry and formal hierarchy allow to define the character and the essence of the project.

To achieve the purpose of this article, we compared a building by each architect, Kahn's Indian Management Institute (1962|1974), in Ahmedabad, India, and Hestnes's Casa da Cultura da Juventude de Beja (1975|1985), in Portugal.

The suggested formal analysis is based on the previously mentioned four aspects presented by Lamas (1993). However, we will name them design | order | form, in dialogue with the function, the spaces quality and the aesthetic communication.

Design | order | form

Even though these projects' dimension is sectorial, in both projects the architects structured them as elements of transition between the street scale and the neighbourhood scale or, as referred to by Lamas (1993), the urban dimension.

According to Kahn and Hestnes, form is always associated with a set of parts that determines a whole, providing the final result with a strong sense of unity.

This strong sense of unity is the result of an evolving and cumulative process. In it intervene the formal, conceptual and material processes, the latter making the whole set visible.

Louis Kahn defines design as something circumstantial, order as what determines appearance and form as something that does not materially exist, something that can be understood as pre-form.

To Hestnes Ferreira, design, order and form are concepts that interrelate and complement each other, willing to overcome the conceptual process.

With the square and rectangular forms, Louis Kahn usually defines the unit. It is through repetition and the proposed relation between units that he obtains the building, granting its unity and formal coherence.

In a line of continuity with Kahn, also Hestnes finds formal coherence in geometry and unit exploration.

This analysis helps to reinforce the formalists' idea over the functionalists' one, that is to say that form in both architects' buildings is much more than a consequence of a function.

Analysing the quantitative aspects in both the Indian Management Institute, in Ahmedabad, India, and Casa da Cultura da Juventude de Beja, according to Lamas (1993), there is a very unique and cohesive reality, developed and tested by Louis Kahn and followed by Hestnes Ferreira.

Dialoguing with Function

This institute's programme would reveal itself to be comprehensive and at a large scale. It included classrooms, administrative areas, a library, students dormitories, faculty and workers residences and other services and premises.

As always, the first thing Louis I. Kahn would do would be having a look into the programme and rewrite it according to his ideas for each space. He wouldn't be intimidated by its restrictive character nor its dimension.

From the beginning, Louis I. Kahn would exhibit a visible distribution according to the spaces required by the programme, dividing the project into specific areas, as he had previously done in La Jolla, at the Salk Institute for Biological Studies. Such a division assumed a hierarchy and simultaneously pointed out the main structure, the school building – although Louis I. Kahn never referred to the spaces in a differentiated manner, as they were all equally important –, where all the school community's functions would concentrate. This hierarchy and space division are only noticeable because Louis I. Kahn has always based his project ideas on one of his fundamental concepts – order.

The school building solution would suffer the most modifications, as it held numerous functions. Kahn's final version would be presented in 1972, although some areas would never

be built. In this plan, his order principle can be observed, as well as a slight symmetry. Its contours resemble the rectangular shape Louis I. Kahn had envisioned from the beginning, creating a united space in which all parts are intertwined. The different functions gather around a central area, the court, where students and teachers should meet. *'The court is the meeting place of the mind, as well as the physical meeting place.'* (Kahn apud Brownlee e De Long, 1997, 163)

Montaner (2002) describes Louis Kahn's ability to differentiate spaces and functions also through the proposed construction system, introducing the double façade, also referred to as membrane wall (Saraiva, 2011).

It is interesting to understand that central spaces assume utmost importance in Louis I. Kahn's architecture, which would be related to his fascination with Italian squares, which he repeatedly drew during his travels to Europe. He was able to capture the essence of those meeting areas and to build them in his works. This same fascination is also present in Hestnes Ferreira's work, in particular regarding Casa da Cultura da Juventude de Beja.

Figure 1. Floor plan, main symmetry centrelines_ Casa da Juventude de Beja.

Casa da Cultura da Juventude de Beja (Picture 1) was the first construction of its kind to be built after 25th April 1974. Because of its use specificity and the population it was addressed to, Hestnes Ferreira intended it to have a festive atmosphere.

Its privileged location, making it visible from every angle, has reinforced its sense of centrality, which has contributed to its formal feature, intensely symmetric.

The central building includes a court at a lower level, from which all other areas develop, clearly representative of both serving and served spaces. The constant search for these two spaces translates into projecting in a continuity line with Louis Kahn.

Spaces quality

Louis Kahn's architecture assumed a constant search for materiality, implying that the choice of material was much more than its function and its technical characteristics.

Materials were used according to their formal and expressive possibilities, simultaneously staying true to them and also to the construction systems, by not hiding them.

This attitude matches Frampton's (1996) definition of Critical Regionalism, assumed by Louis Kahn and followed and sustained by Hestnes Ferreira.

In both architects' work, materials respect the interaction between the light and themselves. The surface texture definition, and how it reveals the light, intensifies even more the proposed space quality. We can say that the revealing of the materials' secret qualities depends on the

shadows that occur when the light diverges from the surface and on how the material absorbs the light.

In both these architects' work, expressiveness is directly related to the concept of light, as the combination between light and shadow highlights the formal composition, originating volume effects on the façades.

According to Leland M. Roth (2005, 77), Louis Kahn stated that light is the most important and significant element in the perception of an architectural work, and as such it should be integrated and worked upon according to its potential.

Urs Büttiker (1993) developed a thorough research on the effects of light on Louis Kahn's work, having created analysis diagrams. In the same line, we present a similar analysis on Hestnes Ferreira's work. (Saraiva, 2011)

Both Louis Kahn and Hestnes Ferreira reveal extreme care towards comfort and quality standards in their work. The pinnacle of this comfort is achieved through the interaction between interior|exterior they suggest in association with the materiality.

In this interior|exterior interaction, the significance of the openings in the built architecture should be highlighted. The way Louis Kahn and Hestnes Ferreira capture the vertical light sets them apart from other architects by their use of geometry in the opening, that is its dimension and form.

Hestnes Ferreira, in his Casa da Juventude de Beja, (Picture 2) materializes this interaction including a small skylight in the cupola centre.

Figure 2. Light entrance scheme _Casa da Juventude de Beja.

Vertical light, as used by Louis Kahn and Hestnes Ferreira, assumes two possibilities and consequently determines two differentiated light spaces.

The first one is related to large scale interior spaces, enabling the intensification of the beam of light projection; the second one occurs when the opening is smaller, directing and intensifying the beam of light, increasing the luminous concentration in one point.

As we can see, the form and dimension of the opening intensify the beam of light, at the same time that they increase the lightness concentration in one point.

According to Hestnes Ferreira, Louis Kahn defined silence as the key to the understanding of architecture.

Kahn, in his drawings for the *Architecture: Silence and Light* conference, defined silence as the wish to be|express, and the light as the wish to be|make. In his perspective, silence also depends on the light diversity, introducing the concepts of *Darkless* and *Lightless*.

Aesthetic communication

Local construction tradition was a defining element in these architects, who have always projecting in respect to it without mimicking it.

Along with this tradition, the respect for the structure and its material is another essential aspect in aesthetic communication.

In Casa da Juventude de Beja (1975|1985), Hestnes Ferreira uses cloister vaults inspired by traditional domes from Alentejo to cover the building, in a total of twenty domes. Brick assumes a double feature, as both structure and coating. The work was so thoughtful that to this day the quality and final image of this element is well preserved in the global context of this building.

Louis Kahn, in his Indian Management Institute project, in Ahmedabad, included the traditional brick arch in the 20th century architecture vocabulary.

The Indian Management Institute buildings translate an unparalleled spiritual quality. This ability in Kahn's work relies on the constant dialogue between light and silence.

Among the different architectural elements, silence can be interpreted as the one that links and synthesizes Louis Kahn and Hestnes Ferreira's works.

Kahn establishes a relation between the concepts of light and silence. Silence represents what is not there, and light what is.

In both architects' work, silence translates into the simplicity and neutrality of spaces and is achieved through the absence of ornament and effortlessness and clarity of the form. Their architecture is defined by homogenous spaces, valued for their light and silence. Both architects convey a Monumental architecture. The Monumentality concept can be defined by the way the building manifests itself, by the identity it transmits, by its use of scale, by its interaction with light and by the way it rouses a reaction.

Conclusions

The university campus in the Indian Management Institute (1962|1974), in Ahmedabad, may be understood as a synthesis of buildings within the comprehensive work of Louis Kahn.

According to both Hestnes Ferreira and Louis Kahn, each architectural work should be simplified, allowing to exclude any element that might confound its reading, in order to achieve its purest aspect.

In part, the range of timelessness in Louis Kahn and Hestnes Ferreira's architecture is a result of their own capacity to observe and reflect on the two most important and always existing entities: nature and Man.

In the perspective of Campo Baeza (2013), the desire that architecture persists in time depends on its capacity of persisting in the memory of Men.

Beauty may only be achieved when architecture is true in its Conception, idea and materialization. This kind of beauty shall not be related to the beautiful and ugly paradox. According to Nesbitt (2008), in 20th century architecture, the reference to beauty and to sublime was repressed both by scholars and architects, eager to break from the past.

Campo Baeza (2013) notices the concept of time in its relation with history, as presented by Heidegger. He summarizes every architect's ambition to accomplish an essential work, able to transcend them, to exist as a part of history and to persist in time.

The truth and beauty motto '*Design with beauty, build in truth*', that features in the London's A.A. Architecture Association coat of arms, is the perfect synthesis of Louis Kahn and Hestnes Ferreira's work analysis.

Louis Kahn's architecture is formalist, intense and true, simple but not minimal as it unveils the essence of architecture.

Hestnes Ferreira, like Louis Kahn, does not project dependent on a style, a trend or a mainstream. By repeating some elements, he creates a unique signature and sets aside the Portuguese national scene. Assuming his own authenticity, his path is the result of a continuous search for the architectural essence.

Acknowledgments

I would like to thank the architect Raúl Hestnes Ferreira for his availability and for providing me with all the necessary material, as well as for all his support throughout the research process. Also significant were the interviews in his Lisbon office, on 12th October 2009 and on 1st April 2010, included as attachment in the doctoral thesis. (Saraiva, 2011).

Relevance study: relationship of morphological characteristics between residential plot and building pattern in Nanjing, China

Qin Zhao

School of Architecture and Urban Planning, Nanjing University, Hankou Road 22,
Nanjing, Jiangsu, P. R. China, 210093. E-mail: zhaoqinwyx@126.com.

Abstract. *Residential plots dramatically contribute to urban form of Chinese modern cities for large quantities. However, just a few studies following Conzenian tradition of urban morphology have been undertaken in China, especially few at the scale of plot. And previous researches about residential plot concentrate on living units or indicators of plot, lacking in thoroughly morphological exploration of relationships between plot and buildings within. Therefore, this paper pays attention to residential plots, describes geometrical characteristics of these plots and building patterns and reveals their relationships. By investigating of 2019 residential plots within urban area in Nanjing, this paper has categorized them in terms of residential building types within plots. According to different shapes, rotation angle of residential plots, how patterns of building arrangement change has been examined. It thus firmly proves that residential building pattern has a relationship with shapes and rotation angle of plot. And through several typical building patterns, how they are affected by geometrical characteristics of plot is demonstrated with boundary condition as well. These discoveries on the relevance of residential plot and building pattern lead to a complete summary of designing rules for residential plots, and are valuable for urban design reference and policy-making.*

Key Words: residential plot; building pattern; morphological characteristics; relevance

Introduction

Background

Chinese cities have seen dramatic changes of urban form with the process of urbanization in past three decades. Especially large numbers of residential buildings for increasing population contribute to these changes, forming notable urban fabric. Plot as a unit of or component of urban fabric has helped to clarify the relation between buildings and the town as a whole (Kropf, 1998). Therefore, it is essential to identify morphological characteristics of residential buildings at plot scale and articulate the formation mechanism of urban fabric.

Nanjing, one of main developed cities in Yangtze River Delta, is a typical Chinese city undergoing extensive development, and residential plots account for nearly 65 percent of all residential and commercial plots. Excluding vernacular dwelling, 2019 residential plots from old town and Hexi new town in Nanjing form sound basis of the study (Figure 1), which provide good examples of all kinds of residential building types and plots over the course of past three decades (Figure 2). Based on mass data of these residential plots, statistics is an effective way to focus on common problems and build up appropriate classification.

Morphological study on plot and residential plot

The Cozenian school founded by M.R.G. Cozen recognized urban landscape into the town plan or ground plan, comprising three distinct ‘plan elements’: streets, plots and block plans of buildings. The plan analysis following Cozenian tradition has been identified as a fruitful

approach in Europe (Whitehand and Gu, 2007), and the study on relationships of plan elements above to analyze contemporary urban fabric was emphasized (Levy, 1999).

Figure 1. All the plots in old town (left) and Hexi new town (right), residential plots are shaded.

Figure 2. Urban fabric formed by typical residential building types and plots in old town (left) and Hexi new town (right).

Morphological studies on modern cities concentrate on streets and their arrangement in a street system (Scheer *et al.*, 2001), plots and their aggregations in block (Siksna, 1997). And this paper pays attention to the plot level. Plot is a crucial notion in building typology and urban morphology, and typomorphological studies is a view of type that shows built structures and their associated open space (Kropf, 1998). Along this acknowledgment comes that plot is a basic unit of urban planning and direct restriction of architectural design, which builds a firm link between building typology and urban form. Therefore, morphological element 'plot' provides an effective tool to clarify the relation between plots and buildings within.

Related studies on plot and buildings within fall into three groups. First one refers to building typology and building patterns. Building types are carefully examined to articulate

physical transformation (Moudon, 1986) and building arrangement in a plot to distinguish plot types has drawn attentions (Kropf, 1998). These studies have some influence on this paper. The second is characteristics of plot, such as density and coverage, are used to describe urban fabric (Lupala, 2002). However, studies of this subject mainly correspond to square or rectangular plots, plot shapes are seldom discussed. Geometrical characteristics of plot are very complicated in Chinese modern cities and are worth studying. Meanwhile, research on plot characteristics is not closely connected with physical form. The third group emphasizes the typological process of buildings (Corsini, 1997; Gu *et al.*, 2008), typomorphological attempt in urban renewal rooted in building history (Maretto, 2005), and socio-economy linked with morphology (Mowla, 1997; Chen, 2012). These studies pay less attention to an overall view of physical form of a city. A few pioneer studies at plot level have been undertaken in China (Whitehand and Gu, 2007; Chen, 2012). As for residential plots, previous studies summarize the basic residential building types (Liu, 2012), and reveal the rules of building pattern within residential plots in a quantitative way (Zhang, and Ding, 2013).

Above all, relative research on residential plot and buildings within has not been widely conducted, especially in Chinese modern cities. This paper accordingly makes an attempt in the direction following Conzenian tradition, and take Nanjing city as an example, trying to uncover the mechanism of physical form in China. Levy emphasizes the distinct relationships between plan elements (streets, plots and block plans of buildings) correspond to the typological analysis of each individual element of the fabric (Levy, 1999). Therefore, in order to articulate the relationships between residential plot and buildings within, building typology and building patterns should be further studied except some existing research.

Types of residential buildings and plots in Nanjing

Residential building types

Quan Liu's research on residential plot in Yangtze River Delta (2013) clearly reveals that natural climate and living habits in China mainly influence the shape of residential buildings. That is the need for southern sunshine, natural lighting and cross ventilation determines the basic compositional rules of basic rooms, limiting the depth of the buildings. Normally, a living unit is composed of several rooms for daily life. A dwelling unit is composed of several living units that share the stairs and emergency exits (including lifts), which are the core of a dwelling unit. According to economic efficiency and safety regulations, living units are organized in various ways, thus forming different dwelling units (Figure 3).

Having investigated residential buildings of old town and Hexi new town in Nanjing, residential building types are sorted into two kinds: slab apartment and tower apartment. Slab apartment is composed of several dwelling units in a row, while tower apartment is only one dwelling unit usually composing at least two living units. Specially, one dwelling unit whose aspect ratio of plan is greater than 1.5 is defined as slab apartment, or it is a tower apartment. And among slab apartments, majority dwelling units are arranged together completely along a straight line, while there exists the types that the dwelling units of same orientation are dislocated along an oblique line (Figure 4).

Residential plot types according to building types

Based on the combination of building types within a plot, residential plots are divided into three categories (Figure 5): slab apartments only; tower apartments only; slab and tower apartments. All 2019 residential plots from old town and Hexi new town in Nanjing are classified according to building types. It is obviously found that residential plots with slab apartments, including both slab apartments only and slab and tower apartments, make up nearly 95 percent of all plots

(Figure 6). In order to articulate the most widespread urban fabric, the scope of the research focuses on residential plots with slab apartment for next analysis.

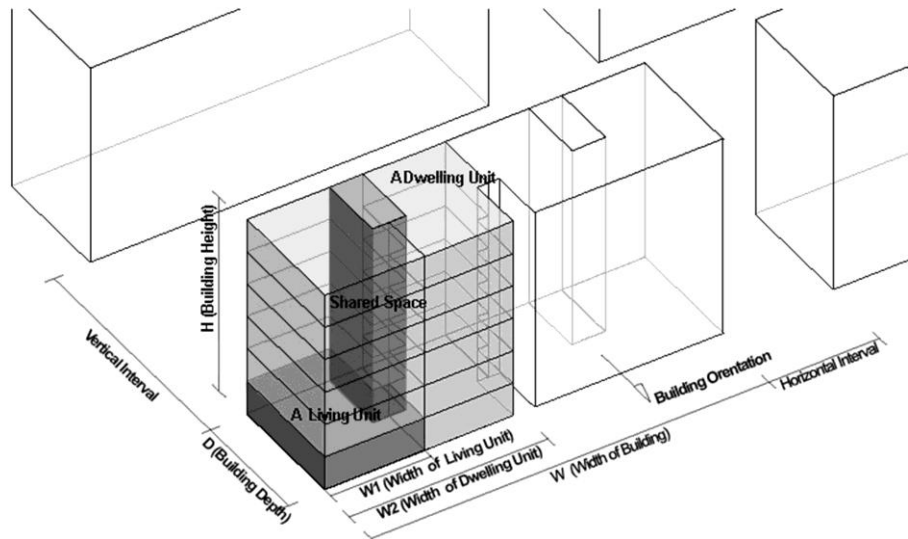

Figure 3. Components of an apartment in China. A living unit is composed of several rooms for daily life. A dwelling unit is composed of several living units that share the stairs and emergency exits (including lifts) (source: Quan Liu, 2013, “Morphological Study on Units of Urban Fabric that Constitute Contemporary Residential Plots in the Yangtze River Delta, China”).

Figure 4. Residential building types are sorted into two kinds: slab apartment and tower apartment.

Figure 5. Residential plot types according to building types.

Figure 6. The quantities of three kinds of residential plot types.

Relevance analysis

Reclassification of residential plots

For it is more complicated to discuss the problem of building pattern based on residential plots with at least two buildings, reclassifying the plots with slab apartments according to quantities of buildings within is necessary.

It is read from the table that among all the residential plots with slab apartments, nearly 86 percent plots are composed of more than one building. Emphasis will be laid on these plots.

Table 1. Reclassification of residential plots.

	slab	slab & tower	Amount	Percent
1	272	0	272	14.3%
>1	1238	397	1635	85.7%
Amount			1907	

Elements of typological analysis

The notion 'plot' is not only one of the morphological elements of town plan, but a significant link between individual building and urban fabric. It is quite important to perform typological analysis of residential plots from a perspective of designing rules of buildings.

For Chinese living habit, sunlight reception and natural cross ventilation are the first consideration, which makes orientation of slab apartment is crucial. Then how geometrical characteristics of plot, such as shape, rotation angle, are correlated with orientation of buildings within are worth discussing. When trying to illuminate the relationships above, boundary condition of plot should be taken into consideration as well. Therefore, the typological analysis of residential plots is based on such elements as below according to designing rules of residential building:

- Geometrical relationship between buildings and plot sides;
- Geometrical characteristics of plot;
- Boundary condition of plot.

It should be declared here that building pattern within plot is related to two factors: how buildings within plot as a whole are associated with plot and the interrelation of buildings per se. This paper concentrates on relationships between plots and buildings, regardless of the latter factor.

Geometrical relationship between buildings and plot sides

For these residential plots with one slab apartment, it is easy to see that about 91 percent of the plots are composed of slab apartment parallel to the plot sides conforming to appropriate orientation of residential building no matter what plot shape. And the rest are regular transformation changing with the plot boundary (Figure 7).

Figure 7. Residential plots with one slab apartment.

By investigating the rest 1635 residential plots with more than one slab apartment, it is explored that there exist three types of geometrical relationships between plot and buildings as a whole (Figure 8):

- a. buildings parallel or perpendicular to at least one side of plot;
- b. buildings totally not parallel or perpendicular to any sides of plot;
- c. part of buildings parallel or perpendicular to at least one side of plot while the rest not, that is the combination of situations above.

Building's side and plot side are identified as parallel or perpendicularity when the angle of the two sides is less than 10 degree.

Figure 8. Three types of geometrical relationships between plot and buildings within.

Figure 9. The quantities of plots following three kinds of geometrical relationships.

Nearly 95 percent residential plots with more than one slab apartment conform to the first geometrical relationship (Figure 9). In other word, no matter how residential plot shapes change, the buildings are arranged along (parallel or perpendicular) at least one side, which suggests that the arrangement of residential buildings within plot, namely building pattern, is mainly influenced by plot edge.

However, not all the building patterns are clearly clarified by such geometrical relationship between buildings and plot sides. On the one hand, it is mentioned above that the need for southern sunshine, natural lighting and cross ventilation shapes the east-west long slab and then constitutes the row fabric of residential areas (Liu, 2013). And through long-time summary of designing experience, the appropriate orientation of residential building in Nanjing ranges from south to south by east or west 15 degrees, which provides more comfortable living environment. If rotation angle of residential building is over that degree in a reasonable range, the living environment is not that good but still accepted. Actually, the statistics shows for one third of residential plots, parts of the buildings within adjust themselves to plot boundary beyond reach of appropriate orientation. On the other hand, while majority residential buildings are arranged in rows within plot, for one quarter of residential plots there are one or more buildings within are totally perpendicular to the rest ones. These types of residential plots need to be further studied according to other elements, such as the geometrical characteristics of plot.

Geometrical characteristics of plot

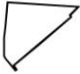

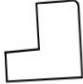

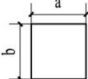

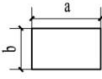

Shape, size, rotation angle and scale of shape are main geometrical characteristics of plot. In this paper, plot shape and rotation angle of plot are mainly discussed to analyze the relationship between plot and buildings within.

Plot shape

All the shapes of residential plots are sorted into 6 categories after carefully examined and reasonably simplified as below:

- Triangle: approximate three straight sides or the length of forth side is less than one third of the longest side;
- Square: approximate four straight perpendicular sides and the aspect ratio is less than 1.5;
- Rectangle: approximate four straight perpendicular sides and the aspect ratio is greater than 1.5;
- Trapezoid: one pair of sides parallel while the rest two sides not, including shapes satisfying condition above with one unfilled or additional shape;
- L-shape: a quadrangle with one unfilled or additional shape;
- Polygon: more than four sides.

Table 2. Categories of plot shape

						
	Triangle	Square ($a/b < 1.5$)	Rectangle ($a/b \geq 1.5$)	Trapezoid	L-shape	Polygon
Regular Shape						
Transformation						
						

Rotation angle of plot

Considering appropriate orientation of residential building, rotation angle of plot is defined here as the angle between bottom side of plot and the horizon for easier description in next analysis (Figure 10).

Figure 10. Definition of rotation angle of plot.

Boundary condition of plot

It is found that two kinds of boundary characteristic of plot that are worth discussing in this paper: next to road, including main road, secondary road and branch road, and next to adjoining plot (Figure 11).

Figure 11. Two kinds of boundary characteristic of plot.

Comprehensive analysis

According to the typological analysis above, 1549 residential plots with more than one slab apartment parallel or perpendicular to at least one side of plot are further studied here with geometrical characteristics of plot. Based on the shape category of residential plots, rules of building arrangement are analyzed comprehensively with rotation angle and boundary condition of plot. Through statistics below, square, rectangular and L-shape plots need detailed discussion for their great proportion.

Table 3. Quantities of plots with more than one slab apartment parallel or perpendicular to at least one side of plot based on shapes

	slab	slab & tower	Amount	Percent
Triangle	11	3	14	0.9
Square&Rectangle	475	61	536	34.6
Trapezoid	204	67	271	17.5
L-shape	331	118	449	29.0
Polygon	148	131	279	18.0
Amount			1549	

Square and rectangular plots

These two kinds of plots are put together for their similar rules of building arrangement, which account for the nearly 35 percent of all plot shapes and can reveal the most common rules. As it has shown that slab apartments are mainly parallel or perpendicular to plot sides, it is easy to imagine that in square and rectangular plots, slab apartments should be arranged in rows at certain angle with corresponding distance between according to the need of sunshine. Actually, about 20 percent of these residential plots are composed of slab apartments perpendicular to each other, thus leading to two plot types: square and rectangular plots with unidirectional slabs and the ones with multidirectional slabs (Figure 12, 13).

For plots with unidirectional slab apartments, rotation angle of plot plays an important role in building arrangement. The rotation angle of square and rectangular plots ranges from 0 degree to 45 degree, among which nearly 98 percent ranges from 0 to 15 degree, that is conform to appropriate orientation of residential building. Therefore, it is valid for slab apartment to be parallel or perpendicular to plot sides while keeping appropriate orientation. When rotation angle of plot ranges from 15 degree to 45 degree, arranging slab apartments along plot sides

regardless of the appropriate orientation may make plot accommodate more buildings and living environment of these slab apartments is still accepted. Such building arrangement is overall consideration of living habits and economic benefit.

Figure 12. Typical square and rectangular plots with unidirectional slab apartments and multidirectional ones.

Figure 13. The quantities of square and rectangular plots with unidirectional slab apartments and multidirectional ones.

The rotation angle of square and rectangular plots with slab apartments perpendicular to each other also follows the rules above, thus majority of buildings within such plots keep unidirectional in rows, while there are small parts of buildings perpendicular to the rest ones. The arrangement of these perpendicular slab apartments correlates with two aspects: boundary condition of plot and designing requirements.

Boundary condition. There are 58 plots within which these perpendicular slab apartments are parallel to plot side next to road, which account for nearly 70 percents of plots with perpendicular slab apartments. Taking function of ground floor into consideration, three quarters of plots with slab apartments parallel to road are commercial-residential types. It thus suggests that these perpendicular slab apartments are the result of overall consideration of residential needs and economic benefit.

Designing requirements. The rest plots with slab apartments parallel to sides adjoining to other plots are preliminarily supposed to be the result of some stage, for that in cases from Hexi

new town lately, such plots are quite rare, while it is more common in old town. The perpendicular slab apartments may be designed to contribute to Floor Area Ratio (FAR). It needs further study on typological process historically.

Triangular plots

In triangular residential plots, though all sides of plot are oblique at different angle, slab apartments are firstly arranged parallel to the sides which are conform to appropriate orientation of residential building. As for the rest sides, they mainly have effect on size of the slabs (Figure 14a).

When one side of the plot is next to road, slab apartments tend to be arranged along the side. Cases show that within some triangular plots, except slab apartments conforming to appropriate orientation of residential building, the rest are totally parallel to the side next to road beyond reach of the appropriate orientation, or the dwelling units are dislocated along the side next to road as mentioned above to keep the appropriate orientation (Figure 14b).

Figure 14. Typical triangular plots with unidirectional slab apartments and multidirectional ones.

Trapezoidal plots

Similar to triangular plots, sides of trapezoidal plots conforming to appropriate orientation of residential building firstly determines the arrangement of slab apartments. Then the direction of unparallel sides of trapezoidal plots makes sense. On the one hand, unparallel sides of vertical direction mainly limit the size of slabs. On the other hand, slab apartments are prone to be organized parallel to the sides of horizontal direction conforming to the appropriate orientation (Figure 15).

Figure 15. Typical trapezoidal plots with unidirectional slab apartments.

There are one third of trapezoidal plots composing of multidirectional slab apartments. Firstly whether side of plot is next to road is still important. Statistics shows that for 75 percent of trapezoidal plots, the slabs within perpendicular to the rest ones beyond reach of the appropriate orientation lies along the side of plot next to road. Secondly, in order to

accommodate more buildings, the shape of ‘trapezoid’ itself determines slab apartments’ arrangement along hypotenuse. Regular trapezoidal plots with one unfilled or additional shape follow the rules as well (Figure 16).

Figure 16. Typical trapezoidal plots with multidirectional slab apartments.

L-shape plots

Nearly 97 percent of L-shape plots are identified as a square or rectangle with one unfilled shape. Therefore, the rules of building arrangement within square and rectangular plots can be applied here. What make a difference specially in L-shape plots is the size and scale of the unfilled shape, in other words, the size and scale of the two wings of L-shape (Figure 17,18). The minimum width of the wings almost equals to the depth of slab apartment.

Figure 17. Typical L-shape plots with unidirectional slab apartments and multidirectional.

Figure 18. The quantities of L-shape plots with unidirectional slab apartments and multidirectional ones.

23 percent of L-shape plots are composed of multidirectional slab apartments, among which arrangement of slabs beyond reach of the appropriate orientation are influenced by two equally important elements, one is still the side of plot next to road contributes to that change, the other one is L-shape itself with two wings of certain size and scale only can accommodate multidirectional slabs. Regular L-shape plots with an unfilled or additional shape still follow the rules.

Polygonal plots

Although polygon is defined as shape with more than four sides, it can be seen as combination of simple shapes (triangle, square, *et al*). After investigating all the polygonal plots, it is found that rules of building arrangement within regular plots (square and rectangular plots) and irregular plots (triangular, trapezoidal and L-shape plots) fit polygonal plots as well.

It is strengthened here that for all multidirectional slab apartments within irregular plots (triangular, trapezoidal and L-shape, polygonal plots), the correlation between arrangement of slab apartments along the side of plot next to road and the boundary condition is similar to the situation in square and rectangular plots.

Conclusions and further work

The paper pays attention to plot level in the light of Cozenian morphological study. By investigating 2019 residential plots from main city and Hexi new town in Nanjing as mass database, residential building typology and geometrical characteristics of plot have been examined. In order to reveal the relationship between residential plot and buildings within, how building arrangement changes with geometrical characteristics of plot is analyzed step by step and demonstrated with boundary condition. Statistics provide effective tools for processing data to articulate the classification in typological analysis.

The geometrical analysis of buildings and plot sides has shown that building arrangement within residential plot is related with such geometrical characteristics of plot: plot shape and rotation angle of plot. For irregular plot shapes (triangle, trapezoid and polygon), hypotenuse of these shapes has obvious effect on orientation or size of building. As for regular plot shapes (square and rectangle), plot angle plays an important role in controlling rotation angle of

residential building except the experiential orientation. Beyond that, plot side next to road as main boundary condition of plot mainly contributes to the change of residential building beyond reach of appropriate orientation.

As the second level of morphological elements, plot links building typology with urban fabric, which prompts the cognition of physical form of Chinese modern cities. In Nanjing, as residential buildings are always arranged along plot sides, the key point of different fabric between old town and Hexi new town is plot, especially plot shapes. Complicated historic-geographical transformation of plots in old town leads to more fragmental plot shapes and more various building arrangement than those in new town.

The study is preliminary analysis of residential plots, more detailed and comprehensive work should be conducted. First, more characteristics of plot need to be taken into consideration, such as size, scale of plot and FAR. Then the tower apartment and interrelation of slab apartment should be included in following research for overall understanding. Furthermore, more precise geometrical analysis of the relative study can be made to summarize designing rules practically. All the achievements will contribute to better understanding of plan analysis following Cozenian tradition in Chinese modern city.

Multidisciplinarity in urban morphology

Multidisciplinarity in urban morphology constitutes one of the ten thematic sessions of ISUF 2014 that wishes to reflect on 'Our Common Future in Urban Morphology'.

The main goal of this session is to encourage new multidisciplinary teams to come together to strength and depth the study of urban form fresh perspectives. Urban Morphology as already recognized by some of ISUF founders and the editor of *Urban Morphology* journal is a field of knowledge that exists for over than a century ago and that was built up throughout the contributions of different disciplines, including, history, geography, architecture, among others. It is precisely on the possibility that urban morphology offers as a potential bridge to bring together knowledge provided by different disciplines that this thematic session has been proposed and encourage reflection and debate upon three specific topics: i) The benefits from the potential of cross-disciplinary knowledge, while bringing together separate disciplines to better contribute to the study of urban form; ii) The need to encourage the formation of new areas of knowledge, while encouraging new multidisciplinary teams to come together in a timely manner in response to identified opportunities as places by *Our Common Future*; and iii) Determine how can urban morphology better determine and evaluate the impacts of urban form on the natural environment and therefore contribute to our common future through sustainability at the ground. In order to reflect on the potential of these three main topics, a group of question was placed by this session to encourage further discussions: Which are the contributions that the different disciplines have imputed to the study of urban form? What advances can be identified from such cross-disciplinary knowledge and what lines of thought are emerging? How and why specific relationships between changes of lifestyle, population growth and urban form can be identified? How can these be measured and evaluated? Which are the impacts of these factors on the natural environment? How to evaluate the dynamics interactions between urban form, water and green spaces? How can urban form better respond to the call for Sustainability?

Teresa Marat-Mendes

The study of urban form versus water management

Teresa Marat-Mendes, Joana Mourão, Patrícia Bento d'Almeida

Instituto Universitário de Lisboa, DINÂMIA'CET-IUL, Av. das Forças Armadas 1649-026 Lisboa, Portugal. E-mail: marat.mendes@gmail.com.

Abstract: *This paper exhibits the on-going results of a research project, MEMO - Evolution of the Lisbon Metropolitan Area Metabolism. Lessons towards a Sustainable Urban Future, which aims to develop a comparative analysis of the metabolic behaviour of Lisbon Metropolitan Area (LMA), in different historical periods (1900-1950-today). The existing relationship between urban form and the access to water is examined, to provide a possible application of urban morphology to face Our Common Future (WCED, 1987). The concept of urban form considered in this investigation includes territorial, urban and rural forms that testify the man will to transform the territory, while providing access to water. Nine types of water elements were identified and analysed against three territorial scales: Municipality, Settlements and Royal Farms. The analysed relationship between the water elements and the access to water contributed to visualise the characterization of the metabolic behaviour of Lisbon Region, in 1900. Finally, this study testifies that specific urban forms of water typologies are preferable than others, at different territorial scales. Thus, testifying the interaction between urban form and water management, but also how and why specific urban forms and territorial arrangements were selected and allocated to better respond to human and environmental needs.*

Key Words: Lisbon region, royal farms, settlements, urban morphology, water

Introduction

Requests for more linkages between sustainability and the study of urban form have already been addressed. As emphasized by Marat-Mendes (2013) and Talen (2014) urban morphology is strategic for the recognition and articulation of the relationships between changes of lifestyle, population growth and urban form, as well as to explore the impact of these factors on the natural environment.

Recent studies focusing the study of urban and rural form (Cakaric, 2010; Ribeiro, 1989), the evaluation of the metabolism of cities (Barles, 2009; Billen et. al., 2009; Gandy, 2004; Niza et al., 2009), and also historical accounts of water infrastructures and cities metabolism (Bocquet, 2008; Barles, 2007; Swaney et al., 2011; Tarr, 1980) evidence that water infrastructures are responsible for urban transformations within cities, rural territories and the natural environment. It is based on this assumption that the study of urban form, conducted by this investigation integrates several forms built by man, including: water infrastructures, territorial arrangements, and urban and rural forms. These are the forms that have contributed to modulate the physical form of the built environment within which man lives and testifies its respective lifestyle.

This investigation analyses the urban form of Lisbon Region against the access to water, in order to identify why and how specific territorial arrangements, water infrastructure typologies and urban-rural morphological units were conceived, while responding to specific human and environmental needs.

This paper is organised in four parts. After this introduction and the description of the adopted methodology, it moves into the analysis of water and urban form evaluation for the Lisbon Region in 1900. More precisely, it identifies and characterizes: i) the territory under analysis; ii) the historical archive and cartographic sources that have informed the analysis; iii) the identified water typological elements; and iv) the territorial units under analysis. Finally, the access to water evaluation is provided in section four.

Sources and method

Study area and territorial scales

The territory under analysis agrees with present LMA administrative limits, which did not exist yet in 1900. Thus, this paper has designated such territory in 1900 as Lisbon Study Area (LSA). Sixty-three charts at scale 1:20.000, elaborated between 1896 and 1905, acquired from the Instituto Geográfico Português (Charts 1 to 34; 36 to 38; 44; 59 to 74; 79 to 82 and; 84 to 85), belonging to Carta dos Arredores de Lisboa (CEM, 1893-1932) (see figure 1) illustrate LSA for the period under analysis. Complementary cartographic and historical sources were also used to visualise the territory under analysis and confront it against the account and characterization of the identified water elements.

The methodology involved an analysis of historic cartography and other original archive documents. Selected data and information for the period under analysis, aimed to identify and characterize: i) water elements; ii) water volumes; iii) population; and iv) urban form.

From the analysed sources and cartography it was possible to identify three territorial scales, according to the availability of needed data: 1) the Municipality; 2) the Settlement; and 3) the Royal Farm scales. Fifteen Municipalities were identified at the municipal scale, as existing in 1900: Alcochete, Almada, Barreiro, Cascais, Lisboa, Loures, Mafra, Moita, Montijo, Oeiras, Seixal, Setúbal, Sesimbra, Sintra and Vila Franca de Xira (Direcção Geral dos Trabalhos Geodésicos, 1907). Sixteen Settlements were identified. These corresponded to the main Settlements of the above identified Municipalities, plus Palmela. The number of inhabitants, the area and the number of dwellings for each municipality were gathered from the 1905 Portuguese Census (DGEPN, 1905).

The 1903 survey on the hygienic conditions of the most important Settlements of Portugal (CMSMOPCI, 1903) and the 1935 survey on the water provision of Portugal Municipalities (CEMOPC, 1935-1936) constituted two important sources regarding water use in LSA Settlements and Municipalities.

In 1900 LSA included a high number of farms (Marat-Mendes, 2011). This paper focuses its analysis exclusively on the Royal Farms, as information about water supply was available for 1904 (CFR, 1905). Ten Royal Farms were identified: Ajuda, Alfeite, Belém, Caxias, Mafra, Necessidades, Pena, Queluz, Sintra and Tapada da Ajuda.

Water supply typologies, Settlements and Royal Farms

The adopted methodology implied: i) geo-referencing the selected cartography; ii) geo-referencing a mosaic map in Geographic Information Systems (GIS); and iii) a web map.

A GIS Survey for the nine water elements, identified from the analysed cartography and geo-referenced in the mosaic map provided an innovative database of aqueducts (including underground aqueducts), fountains, springs, tanks, tide-mills, water mills, water mines, water reservoirs, and wells (see figure 2), totalizing approximately 3.800 units (see figure 3, table 1 and table 2)

The location and the relative position of all water elements, at the sixteen Settlements and at the ten Royal Farms, within LSA, were also identified.

At the Settlements scale the perimeter of the built area determined the polygons that allowed measuring each Settlement area (see table 3). An overview of these sixteen Settlements, within in their established limits, at the same scale (except for Lisbon) is provided in figures 4 and 5. For the ten Royal Farms, the GIS survey was complemented with data and information provided by the 1904 report (CFR, 1905). Additional aqueducts, fountains, pipelines systems, springs, tanks, water mines, water network and wells were identified. When present, the Royal Farms inherent Royal Properties were also identified. These were considered for the delimitation of the Farms polygons, bounded by the farms walls and surrounding roads (see table 4). An overview

of these ten Royal Farms, within in their established limits, at the same scale, (except for Mafra), indicating water elements is provided in figure 6.

Access to water in Settlements and Royal Farms

Following the cartographic treatment, and based on the geo-referenced cartographic mosaic, it was developed a comparative systematization of the access to water for the sixteen identified Settlements and ten Royal Farms. Information provided by the 1903 and 1935 surveys, but also by the 1904 report, was used for this systematization.

This systematization required the establishment of a standard graphic representation. This informed about the location and the relative position of water elements to the Settlements and Royal Farms. No scale consideration was required.

Four relative positions of the localization of water elements in Settlements were identified: 1) in public space; 2) inside the Settlement; 3) at the Settlement border; and 4) in the vicinity of the Settlement. For these last ones, it was considered elements existing within a radius of 1 Km approximately (see figure 7).

Two relative positions of the localization of the water elements in the Royal Farms and their inherent Royal Properties were identified: 1) inside the Royal Farm and; 2) inside the Royal Property (see figure 8). The relative position of the Royal Farm to nearby Settlements was also represented.

Water elements considered in these analyses did not cover the nine identified water elements. Water reservoirs and water mines were excluded from the Settlements analysis, as these were inexistent. The analysis was based on the observation of the water elements within, at the border and in the vicinity of the delineated polygons, which gave a very subjective detail. For the Royal Farms, the 1:5000 scale plans of water distribution within the Royal Farms provided by the 1904 report, allowed to complement this analysis with greater detail. Nevertheless tide mills, water mills, water mines and water reservoirs were excluded from the accounting, as these were inexistent within Royal Farms. The number of water elements in each identified Settlement and Royal Farm, and the rate of water elements per area unit, is provided in tables 3 and 4.

Water and Urban Form in Settlements and Royal Farms

The present section follows with a brief description for each Settlement and Royal Farm. Gathered information includes: location; elevation, water elements, water supply net, building form, public space availability; and land uses. An account of the inhabitants and dwellings was also provided for Settlements description.

Settlements

Vila Franca de Xira (5-25 meters above sea level, MASL) located beside Tagus River and North railway, in 1911 housed 4873 inhabitants in 1220 dwellings. No water network was present in 1935, and in 1903 this Settlement was supplied by one fountain, two municipal wells for irrigation and washing and also by private wells. Buildings were distributed along the access roads in narrow blocks and beside the railway, in large scale closed blocks with vineyards in the inner space.

Mafra (210-230 MASL) located beside the Convent of Mafra, in 1903 housed 2175 inhabitants in 387 dwellings. In 1935 it had no municipal network, except a municipal pipeline located at the Royal Farm. Water was sold by watermen and collected in two fountains, next to the convent and the Royal Property entrance. The Settlement was distributed along two radial roads, starting from the main entrance of the convent. In the vicinity vineyards and pinewoods were located.

Loures (20-45 MASL) located along Malveira hills, in 1903 housed 457 inhabitants in 118 dwellings. A high slope, at 110 MASL, surrounded *Loures* where spring water was brought by an underground aqueduct to the central fountain, where the water was free. In 1903 the water network was only provided for the City Hall and Military buildings. Water was sold to the remaining buildings. The Settlement, formed by three radial short rows of buildings was surrounded by ploughed land.

Sintra (160-200 MASL) in 1903 housed 2856 inhabitants in 753 dwellings. One water network existed since 1855, although private and partial. In 1914 there was a municipal network and in 1923 also a private company network was developed, which provided one fifth of the water for municipal use. Altogether these networks supplied fifteen fountains. One fountain was located in a public space inside the Settlement. The Settlement was surrounded by trees and by a valley with several water mills.

Cascais (5-20 MASL) located by the sea, in 1903 housed 2536 inhabitants in 876 dwellings. Several springs and fountains, where the water was free, served it. Additionally, two

underground aqueducts supplied a partial network since 1894, which served 1173 dwellings in 1935. Six springs and one well located in public spaces were also present. In the vicinity land was not cultivated except for a small vineyard, an orchard and pinewoods near the fortress.

Oeiras (10-35 MASL) located near Tagus River, in 1903 housed 1.776 inhabitants in 455 dwellings. A private company developed a water network in 1919. Previously, the water available for human consumption was sufficient. It was obtained from private wells along a waterline, from one spring and one water mine. Water was freely available at the fountains located on the main access roads, in the way out of the Settlement. The buildings were distributed along these roads, close to vegetable gardens, orchards and vineyards.

Lisbon City (10-70 MASL) stands at Tagus estuary surrounded by the railway. It housed the majority of the municipal population, 352.715 inhabitants in 81.021 dwellings, in 1903. The Aqueducts of Águas Livres and Alviela supplied houses and fountains. In 1851 (Andrade, 1851) counted more than fifty fountains, seventeen pipelines and six wells. From 1880 onwards a water network served Lisbon. Vegetable gardens and trees were located within the Settlement. In its vicinity, land was cultivated with orchards, vineyards, olive trees and ploughed lands.

Located beside Tagus River, *Alcochete* (3-15 MASL) in 1903 housed 3506 inhabitants in 937 dwellings. The small and compact Settlement had a public square with a municipal well that in 1905 was replaced by a fountain. The water network was installed in 1918. Previously, water was supplied by private wells and tanks located within the Settlement and its surroundings. Along the river there did vineyards and orchards, while the remaining Settlement was organized in small blocks, surround small rows of buildings perpendicular to the margin.

In 1903 Montijo (2-15 MASL) housed 7.010 inhabitants in 1687 dwellings, which corresponded to 70% of the municipal population. In 1903 the drinking water was distributed by car, provided by wells, four of them were inside the Settlement. In the vicinity there were two tide mills with basins contiguous to the urban form. The Settlement had large empty spaces, two with public wells in the centre. The ploughed soil was found inside the urban fabric, protected by a walled road by the riverside.

Almada occupies an elevated promontory (75 MASL). In 1903 it housed 3162 inhabitants in 815 dwellings and was developed with linear rows of buildings forming large blocks, bounded by ploughed land and vineyards. In 1905 there were no water elements inside the Settlement. One fountain was present at the riverbank. In 1935 there was still no water network, but there was one spring and one fountain in the highest part of the Settlement, providing free water public supply. Until then, water was distributed in barrels and in pitchers.

Barreiro (5-15 MASL) is surrounded by Tagus River and by tide mills basins. In 1903 it had 5206 inhabitants and 1419 dwellings. Small compact blocks were concentrated on the north side of the Settlement and along two access roads. Until 1927, when the water network was built, water supplied by wells was abundant. In 1935 the network served 287 dwellings and water was still being sold by the Municipality to the watermen.

Moita (5-30 MASL) is located in a long recess of the Tagus estuary with salt basins. In 1903 it housed 6850 inhabitants and was served by wells and by one fountain located on a public space. In 1925 the water network collected water from wells, and in 1935 it served 105 dwellings. The buildings were distributed through three linear rows. One formed by quadrangular blocks next to central water basin. Cultivated land and vineyards surrounded the backyards of the Settlement. At the southern end of this basin a tide mill and salt basins limited the Settlement.

Seixal (0-15 MASL) stands on a recess of the Tagus estuary. In 1905 a riverside road and a landfill with pinewoods surrounded it. In 1911 housed 2769 inhabitants in 614 dwellings. It was supplied by five wells; two of these were public with free water, and by one fountain located on a public space at the east side of the Settlement. Small compact blocks, including two green areas along the river, built the urban form. In 1935 there was still no municipal water network.

Palmela (160-190 MASL) is placed on a hillside. In 1903 it housed 2490 inhabitants in 690 dwellings. One spring located in the base of the hill and one public well supplied the population in 1903. Six public wells and four fountains complemented these water elements in 1935, while

there was no distribution network. The Settlement is arranged along the slope with trapezoidal blocks. Due to the topography cultivated land was not contiguous to the Settlement. Yet, at the vicinity there were vineyards on the southern slopes, but also olive and cork trees.

Setúbal (0-20 MASL) is a city that stands next to the Sado River. In 1903 housed 20,027 inhabitants in 5869 dwellings. Watermen sold water network dates from 1896, when the inhabitants were still served by wells and water. In 1905, one fountain and one spring existed in public space. There were no wells within the Settlement but in its vicinity there were twelve of them supplying the network. The city had green spaces beside the large closed blocks, at the river.

Sesimbra (10-35 MASL) is located at the seacoast. In 1903 it had 5,104 inhabitants in 1483 dwellings. Water network was available since 1909, although fountains only used such water in some parts of the year. Before, was supplied by wells (one in the main public square) and two fountains. Narrow streets and orthogonal blocks structured the compact urban form. Flanking the access roads to the Settlement the land was cultivated with cereals and vineyards. Olive trees were present along the waterlines.

Royal Farms

Mafra Almoxarifado (230-356 MASL). Almoxarifado corresponded to a number of lands that belonged to the jurisdiction of an Almoxarife, whom was treasurer of the Royal House. In 1900 the waters that supplied these properties were obtained within the Tapada of Mafra (a Hunting Reserve) or in the lands belonged to the Royal House. Without the obligation to supply any others, the Municipality of Mafra such as other buildings did also served by some of these sources. From the nearly fifty sources, four were piped. Apart from the Aulas Fountain, twenty other sources supplied the Royal House and the Cerca Garden. Most of the property was cultivated with pine and other trees; Frades vegetable garden was watered by two springs.

In 1904 Sintra Palace (200 MASL) was supplied by water from two aqueducts: Serra Aqueduct, whose waters were also served by some privates; Sabuga Aqueduct, that supplied the lake located in front of the Royal House and watered the Preta Garden. The distribution of the Sabuga leftovers was of the responsibility of the Municipal Council, without prejudice of the public and the Royal Palace.

The Pena Royal Property (380-529 MASL) principally consisted of woods. Because of this elevated location, in 1904, the 72 sources that supplied the Pena Almoxarifado consisted of mines, tanks, lakes, and sources and spring whose origins sprouted from the properties of Pena Park (explored since 1838). Several other buildings and private farms were also supplied by these waters, both for human consumption and irrigation.

Queluz Royal Farm (100-140 MASL) is located in the municipality of Sintra. In 1900 more than eight water mines and sources provided the water catchment. One of these sources was at a distance of 2kms from the Royal House. Although a river with a dam crossed the Royal Farm, the water was also brought by three aqueducts that supplied one spring located within the Royal Farm; one spring located on the main square of Queluz; and one public fountain in the northern edge of this village. In 1898 the ploughed lands occupied the Royal Property. Near the Royal House garden and woods occupied the soil.

The property where is located the Ajuda Royal Palace (85-110 MASL) was bounded by a road. In 1904 the waters provided by mines and wells supplied this almoxarifado and were distributed by piping systems. These were used to serve the Royal House, three public fountains, and the irrigation of ploughed fields and gardens. There was no municipal network. Telheiros and Quintinha residents were served by the Palace water mines and in case of fire, water should be provided by the Royal House water.

The Tapada da Ajuda (25-160 MASL) property was bounded by walls and cultivated with several types of trees and ploughed lands. This was located within the municipality of Lisbon. From the piping systems built up to 1904, some of them supplied also some buildings located within the Royal Property, such as a lake, orchards, vegetable gardens and the Calçada da

Tapada spring. Among the eight sources whose origins were located within this Tapada, two water mines were owned by other properties: Belém Royal Farm; and Saldanha Farm.

Necessidades (30-60 MASL) is located within the municipality of Lisbon. The quantity of water produced in this property that ran into the Royal Farm woods would gather 12 Pennas (1 Pena measured approximately 3390 litres/24h) from the Águas Livres Aqueduct. In 1904 the waters from the Almarjão mines, apart from supplying the Palace, also supplied four springs located outside the property, placed in public spaces, such as lakes, tanks and one waterfall located in the Royal Park, stables and the Queen garden.

Caxias Royal Farm (10-42 MASL) is located along the coastline. The property was surrounded by walled road and was cultivated with olive trees, vineyards and other trees. In 1904 the Barcarena River, next to the Royal Property, was dammed just below Laveiras village and its waters were used for irrigation and supply the Cartuxa Convent and other private properties. The Royal House and the cascade fountain were supplied by water from the Queijas Aqueduct. This also supplied the spring located in the courtyard of the palace, the public fountain from Queijas and other close palaces. One well situated next to the cascade provided abundant water for irrigation.

The Belém Royal Palace (5 and 114 MASL) is situated on the margins of the Tagus River in the municipality of Lisbon. In 1901 the water that watered the orchards and gardens of this property was provided by a well located in the Belém Royal Farm. These waters, despite of being an abundant source, were not enough for the required consumption. The public and private houses consumed the waters from the three groups of water mines in large quantities, collected from springs. The water source located on the west side of the Ajuda Royal Palace was connected to the Belém Royal Farm pipeline.

The Alfeite Royal Property (5-60 MASL) is located on the south bank of Tagus River. In 1904 the Royal House was supplied by water from one well and by the Municipality of Almada, through a contract from 1890. The property was cultivated mostly with pinewoods, some olive and other trees. The Brejo da Romeira ditch, whose waters were elevated by a dam, irrigated the nearest lands. Three wells watered the orange orchard. The water provided by this Almojarifado sources was all consumed in this property.

Discussion

This section moves into a comparative analysis of the access to water in the analysed LSA Municipalities, Settlements and Royal Farms.

For the total area of 2935 km² LSA housed 567 thousand inhabitants in 1900, and presented a total of 3732 water elements. Table 1 and table 2 allow characterizing the average number of water elements per km² and per inhabitant. However, it should be stressed that these densities do not testify the water elements efficiency in terms of quantity of water supplied. Moreover, the distribution of water elements over the territory is not homogeneous as indicated in figure 3.

It should be noticed that the density of water elements per area is not always proportional to the density of water elements per inhabitant. Thus, some Municipalities with a high population density do not always present a high density of water elements per area. The case of Lisbon is exemplar: while presenting the highest population density, it presents the lower rate of water elements per inhabitant. Additionally, scarcity of water in Lisbon was a problem already identified by Montenegro (1895). A further analysis of water volumes account is needed to better inform about this heterogeneity of water elements distribution.

Water elements in LSA and in its main Settlements follow a growing hierarchy in complexity, from the simple well or direct water source to the more complex spring where man, often conducted by an aqueduct, drives water. Such hierarchy responds to the natural hydrographical conditions and to the population needs.

Wells were more common and numerous at the Municipalities and Settlements of south area of LSA, while springs and fountains were more present at north area (see figure 3). The presence

of water elements within public spaces occurs in the majority of the Settlements. Three Settlements without public spaces do only present water elements within their border areas (see figure 7). Lisboa and Setúbal present a greater number of public spaces and water elements variety within such areas. These are the most important cities.

It is evident from the description of all Royal Farms the presence of a complex network of water pipelines and aqueducts for irrigation and human consumption (see figure 8). Half of the Royal Farms had water infrastructures that connected to public springs. A considerable number of Royal Farms allowed privates to collect water directly from their sources. Two of them supplied a municipal water network (Mafra and Pena) and one received water from the municipality (Alfeite), testifying the articulation between Royal Farms and Settlements in what concerns to access to water in LSA in 1900.

The provided tables allow an account of the various water elements in each analysed Municipality, Settlement and Royal Farm. Their comparative analysis allows concluding that in Municipalities and Settlements wells represent the predominant water element per Km² and also the presence of a great variety of water elements. However, at the Royal Farms it is evident a uniformity in the distribution of the total water elements. Yet, some Farms present a higher number of water elements than others. Water Mines are the most numerous water elements but Aqueducts and Pipelines are present in all Farms.

Conclusions

A characterization of the access to water in LSA in 1900 was offered in this paper, although conditioned by available sources. The analysis and confrontation of historical governmental surveys and cartography proved to be adequate to the investigation methodology. Such information did not cover all the needed data for the full account of the urban metabolism in LMA, as referred by Barles (2009). Nonetheless, the present analysis contributes to visualise the water use and the characterization of water flows that operate within the LSA metabolism.

The analysis of access to water in LSA has confirmed the existence of a hierarchy of water elements, supported by the complexity of their infrastructure and involved costs. This analysis also reveals an existing relationship between Settlements and Royal Farms, in what concerns to water management.

The overall distribution of water elements in LSA confirms their relationship with geographical conditions, population concentration and territorial arrangements. Thus testifying the interaction between territorial, urban and rural forms, and water management.

Finally, this paper has verified that the localization, type and number of water elements are determined by pre-existing territorial structures, but also determines future urban form structures.

Abstract. *The principal aim of this paper is to construct a new spatial typology of the Metropolitan Urban Areas (MUA), based on four metropolitan processes: concentration, dispersion, centralization and decentralization. It is at the same time, a theoretical and multidisciplinary approach that rest on works of many Francophone and Anglo-Saxon researchers. In this context, it is necessary at the first step, to determinate for each spatial type, morphological (localisation/land use) and functional (mobility/transport networks) characteristics of MUA and to specify at the second step, their evolution according to the centrifugal mode.*

Key Words: *spatial typology, metropolitan urban areas; metropolitan processes; morphological and functional characteristics.*

Introduction

Through the literature, we note the abundance of concepts and alternative models in order to find a solution to urban sprawl phenomenon and designate the most sustainable urban form: polycentric city, urban corridors, smart growth and new urbanism. These models are in the centre of the current debate whose the crucial question is: what's the urban form that promotes a more sustainable society?

We distinguish a variety of urban forms across the world and specifically in Europe: monocentric versus polycentric forms, centralized versus dispersed models. We classify these urban forms in several geographic scales: neighbourhood, city and metropolitan area (Tsai, 2005). The neighbourhood and the city are included in the metropolitan area, so, the metropolitan scale seems to be the most pertinent to understand the spatial organisation of Metropolitan Urban Areas (MUA).

In general, spatial structure of MUA can be defined as 'the overall shape, may characterise such land use phenomena' (Tsai, 2005) and refers to 'the set of relationships arising out of the urban form and its underlying interactions of people, freight and information' (Rodrigue et al., 2009). These two pertinent definitions gathering both land use and relational aspects show that the understanding of spatial organisation of MUA is conditioned by two things: morphology and functioning.

The reflection initiated today seeks in particular to deepen links between morphological, functional and structural aspects of the city and the challenge of sustainable urban development. In this context, this paper tends to know morphology and functioning of MUA by using a theoretical and conceptual approach. This paper is divided into five sections on, respectively: the definition of metropolitan processes, the construction of new spatial typology, the MUA's morphological and functional characteristics, the evolution of MUA according to centrifugal mode and the example of a metropolitan territory named G10.

Definition of metropolitan processes

MUA as a term is used to configure a statistical unit which can extend up to several tens of kilometres from the city centre; it includes both city and urban area (Roger, 2007). It may

correspond to 'a major city together with its suburbs and nearby cities towns and environs over which the major city exercises a commanding economic and social influence'¹⁶². In addition, MUA is a functional and scalable territory (Conesa, 2008) since it corresponds to the influence area of metropolis (etymologically mother city). In terms of threshold, French metropolises are spaces with 500 000 inhabitants at least which include one urban area of more than 200 000 inhabitants and involve several medium sized cities (DATAR, 2004).

In a context of globalisation, MUA defines the territorial system concerned by metropolisation, the major urban phenomenon of the last fifteen years (Roger, 2007). Metropolisation is 'a protean and contradictory phenomenon which now works both urban spaces and national and international urban framework' (DATAR, 2012). Researches on metropolitan processes are conducted in several fields such as economy, geography and town planning. Among processes that accompany metropolisation, we have dilatation and stretching frame, concentration and decentralization, increase and diversification of mobility, logics of residential and economic localisations, rural–urban confusion and pressure on natural and agricultural spaces.

Four contradictory processes catch our attention in order to build a spatial typology of MUA: concentration, dispersion, centralization and decentralization. It is necessary to define these terms basing on a theoretical corpus and taking into account the most significant definitions.

Concentration reflects the high density and represents monocentric development (Gordon and Richardson, 1997). It is a condition to improve accessibility (Pouyanne, 2004) and concerns employment and dwellings (Ewing, 1997). It opposes to urban sprawl and integrates a high functional diversity. Furthermore, the concentration of development is required by the compactness (Tsai, 2005), thus, monocentric and polycentric compact forms (Anderson *et al.*, 1996) require the concentration of development. Concentration refers also to clustering term. According to Rodrigue *et al.* (2009), clustering is the setting of activities in relation to a specific part of the urban area. A cluster of activities is therefore a concentration around focal point which can be a transport infrastructure (example of station) or a smaller town that has been absorbed by the metropolis expansion.

Dispersion called also decentralized sprawl (Ewing, 1997) designates the urban sprawl. It is characterised by discontinuity (Tsai, 2005) and low density. Newton (2000) explains that dispersion is a suburban low density development concerning population, housing and jobs. Moreover, dispersion is the diffusion of spatial components according to principle of automobile accessibility and it opposes to concentration which correspond to the agglomeration of components according to principle of proximity (Secchi, 2002).

Consequently to concentration and dispersion processes well known of the economic geography, two opposing forces occur within the urban system with the obligatory presence of transport networks: centrifugal and centripetal forces.

Centripetal forces push to concentration (Duranton, 1997) or agglomeration. Among the agglomeration factors, we have for example the proximity of firms to exchange information, existence of fixed costs, availability of labour, etc. Centrifugal forces push to differentiation or dispersion (Duranton, 1997) and they are the result of many factors such as increasing land costs in the centre, congestion, space consumption, transport costs, etc.

Centralization refers to the setting of activities in relation to the whole urban area (Rodrigue *et al.*, 2009), so, centralized cities gather more than 60% of jobs in the centre¹⁶³ while decentralized cities have less than 40% of jobs in the centre (Aguilera and Mignot, 2004). In Switzerland, decentralization doesn't concern only workplaces; it represents dispersed housing zones situated in rural areas at some distance from agglomerations (Meyre and Stalder, 2006).

¹⁶² <http://global.britannica.com>.

¹⁶³ The authors designate centre in contrast to periphery.

This is confirmed by Bertolini (1999) who clarifies that decentralization is the remoteness process of houses toward suburbs and peripheral zones.

In their paper titled 'spatial structure and productivity in US metropolitan areas', Meijers and Burger (2010) are interested in localisation of the metropolitan population. They have mentioned that population either it localises in urban poles or it disperses with decentralized manner on metropolitan territory. They confirm that localisation of the population is related to 'centralization–dispersion' dimension. Moreover, Bertolini (1999) explains that concentration and decentralization are concomitant because economic functions like production can decentralize contrary to business services which need to concentrate. Pouyanne (2004) stipulates that there is a double movement because firms detach from centre to peripheral zones where they tend to gather and to concentrate.

Finally, the World English Dictionary attributes two pertinent definitions to decentralization in closed relation with concentration and dispersion. 'To decentralize is to distribute the administrative powers of functions of a central authority over a less concentrated area. It is also to reorganise a government, industry, etc. into smaller more autonomous units'. This first definition related to administration shows that decentralization is the process of transferring some of power exercised by state to political or administrative entities of lower level (Bussi, 2010). 'In France in 1980s, decentralization was synonym of state modernisation and democracy deepening. It was questionable to organise best repartition of political competences between centre and periphery entrusting new missions to local authorities and shortening decision times' (Levy and Lussault, 2003; Bussi, 2010).

'To decentralize is to disperse something from an area of concentration. In other words, it is to disperse a concentration, as of industry or population'. This second definition of the dictionary completes and coincides with Bertolini's definition.

Table 1 recapitulates concisely what we mean when we refer to concentration, dispersion, centralization, decentralization.

Table 1. The recap chart

Concentration	Dispersion	Decentralization	Centralization
monocentric forms	decentralized	dispersion	concentration
polycentric forms	sprawl	distance from the metropolitan centre	proximity to the metropolitan centre
compact forms	low density	peripheral localisation of people, employment and activities	localisation of people, employment and activities in metropolitan centre
high density	discontinuity	competences organisation between centre and periphery	functions exercised by a central authority
continuity			

Corollary, we propose personalized definitions (figure 1) of the four metropolitan processes:

Centralization: is to centralize population, economic activities, employment and major equipments (cultural, of transport...) in the metropolitan centre of commandment.

Decentralization: is to disseminate the components mentioned above to metropolitan limits generating shrinking of the centre in terms of demography, activities, etc. This shrinking can't be quantified in terms of surface (voids can be filled through urban renewal operations).

Concentration: is to gather population, activities... around a focal point upon specific metropolitan parts which can be the main centre or any geographical zone. Specialized concentration (residential, economic or other) is at the origin of cluster formation. The emergence of small non-metropolitan secondary centres is both the consequence of decentralization and concentration.

Dispersion: is the inverse of the concentration action, it consists to delete the logic of clusters spontaneously or regularly (central disjunction followed by localised and peripheral concentration).

The concentration/dispersion tendency is related to a key factor which is land. Inversely, the centralization/decentralization tendency is related to existence of transport infrastructure (road, rail, highway...).

Figure 1. The four metropolitan processes.

Construction of a new spatial typology

If we link the four terms, we will obtain four spatial models which may characterise a MUA: centralized concentration; decentralized concentration; centralized dispersion and decentralized dispersion.

Centralized concentration may represent a compact or a monocentric metropolitan area. Decentralized dispersion may correspond to a diffuse metropolitan area. Centralized dispersion has not a theoretical basis or a set of conditions that can define it.

Decentralized concentration is the intermediate model that may represent a polycentric or a multi-polar metropolitan area. Morphologically, decentralization occurs in metropolitan territory from the centre to secondary polarities whereas concentration occurs in these poles.

In theory, decentralized concentration aims to decrease polarization of the metropolitan centre, multiply polarities and encourage urban growth around nodes and transport networks (figure 2). In Europe, decentralized concentration is a planning strategy which has emerged in Germany in 1993 and a principle announced in Swiss federal law on town and country planning.

Figure 2. The decentralized concentration.

MUA's morphological and functional characteristics through researchers works

Basing on the works of many researchers and according to the typology cited above, we try through this section to determinate morphological and functional characteristics of MUA.

Works on morphology

Through his paper titled 'the development of spatial structure and regional economic growth', Parr (1987) has defined three distinguish cases of spatial structure development in relation with the economic growth: regional concentration and metropolitan centralization, regional concentration and metropolitan decentralization, regional deconcentration and metropolitan decentralization. We explain in each case, economic and migratory factors which influence the population and the employment localisation at metropolitan and regional scales.

Regional concentration and metropolitan centralization (figure 3): in this first case, the economic growth process is recent, the income per capita is low and the demographic growth is rapid in the metropolis but slow in the non-metropolitan part of the region. Here we have two situations. Firstly, when regional economy is in the process of industrialization and economic activities are concentrated in the metropolis due to forces of agglomeration economies, it will have a net migration from the non-metropolitan part of the region towards metropolis as well as a net international and interregional migration in the direction of metropolis.

Secondly, when growth of the non-metropolitan part stimulates growth in the metropolis, it will have a net substantial international and interregional migration towards metropolis and the non-metropolitan part with a low intra-regional migration towards metropolis. As a consequence of these two situations, the concentration level of regional population will increase and will be accompanied by the centralization of population in the metropolis.

Regional concentration and metropolitan decentralization (figure 4): in this second case, the region has known an economic growth in a certain time and the income per capita is situated at a superior level. The demographic growth increases in metropolis limits and especially in the internal non-metropolitan part of the region. The superior income of population and the low cost of transport system facilitate this decentralization of population. However, the external non-metropolitan part knows slow and negative rhythms of demographic growth. Moreover, the forces of agglomeration economies and low cost of interregional transport promote the concentration of activities and the centralization of employment in the metropolis. So, we note a net international and interregional migration towards the region and especially the metropolis. Consequently, the concentration of regional population increase is accompanied by the decentralization of the metropolitan population.

Figure 3. Regional concentration and metropolitan centralization.

Figure 4. Regional concentration and metropolitan decentralization.

Regional deconcentration and metropolitan decentralization (figure 5): in this third case, regional economic growth and the income per capita are relatively high. The housing demand in zones of low residential densities continues to rise up because of the high income of the population. So, demographic growth rates are negative in the metropolis and positive in the non-metropolitan part of the region. This decentralization of population is also associated to the decentralization of employment in order to escape the negative externalities of metropolis such as congestion, pollution and criminality. Additionally, the firms move away from the metropolis to take advantages of the non-metropolitan part of the region: accessibility of land and the more interesting costs of transport and communication systems.

Two situations are associated to these developments: the first is characterised by a net migration from the metropolis towards the non-metropolitan part of the region while the second indicates a net interregional migration in the region. These tendencies cause in consequence the deconcentration of regional population which is accompanied by the metropolitan decentralization of population and employment.

Globally, Parr has stipulated that the spatial development of metropolitan region can directly pass from a phase similar to the first case to a phase similar to the third case. The intermediate phase is nonexistent or short. Additionally, he has explained that we can imagine a fourth case of regional deconcentration and metropolitan centralization but it's difficult to invent a coherent set of conditions which can explain this development of spatial structure.

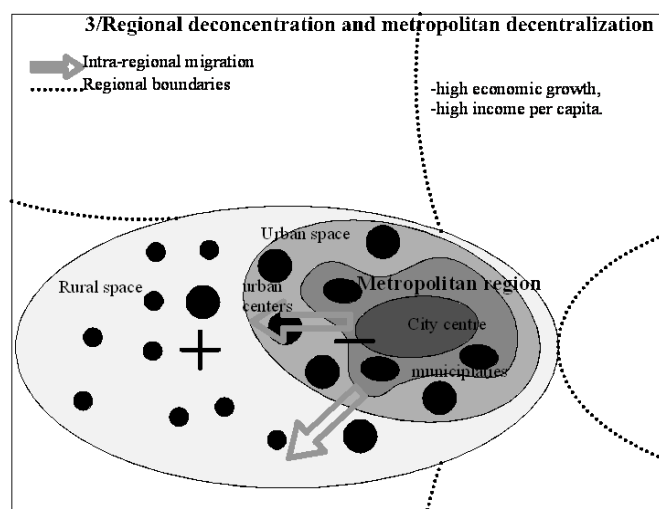

Figure 5. Regional deconcentration and metropolitan decentralization.

Brotchie triangle allows us to understand the different relationships between concentration and dispersion of activities and displacements (Simmonds and Coombe, 2000). It's a simple graph (figure 6) whose the horizontal axis measures the concentration of employment (in terms of the average distance between employment and centre) and the vertical axis measures the average distance that residents travel to work (this distance is conditioned by localisation of residents and jobs). Only the triangle's summits interest us because they represent three theoretical situations:

Point A represents a metropolitan area characterised by centralization of employment and radial home-work trips (the residents travel to centre for working). This first situation reflects the centralized concentration model.

Point B represents a metropolitan area characterised by decentralization of employment, dispersion of population and long distance home-work trips. This second situation represents the decentralized dispersion model.

Point C represents a metropolitan area characterised by decentralization of employment and localisation of home-work trips (each active walks to the nearest workplace, so, it's a local concentration of short distance trips). This third situation indicates the decentralized concentration model.

Besides, Gilli (2005) stipulates that economic activities don't scatter with the same manner and deconcentration can be non homogenous for all sectors. When sectors scatter in the same manner, it means that they undergo spatial horizontal disintegration. This disintegration could be partial if deconcentration has only concerned some sectors. It's the example of an area where population is decentralized to periphery generating an increase of peripheral potential merchants which attract new activities. When sectors relocate and don't scatter, it means they undergo spatial vertical disintegration. This second type generates specialization of urban spaces in different complementary activities.

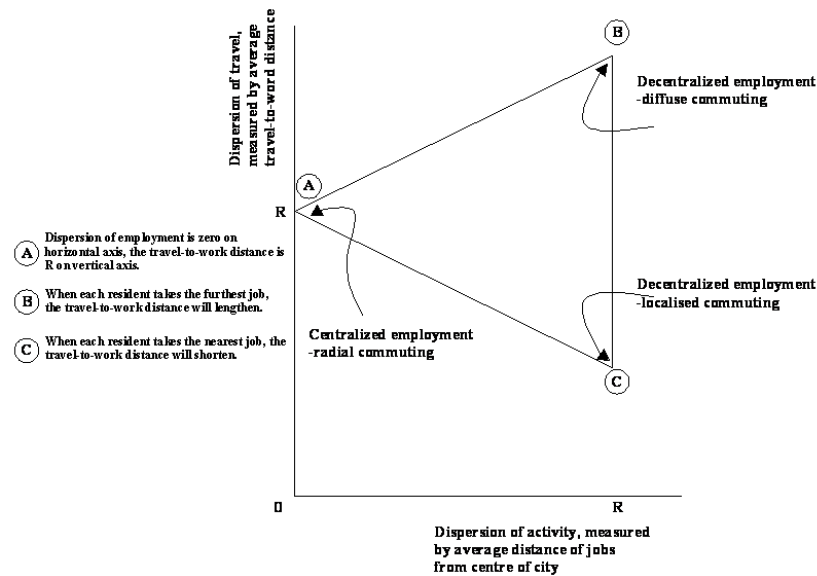

Figure 6. The triangle of Brotchie (source: Simmonds and Coombe, 2000).

According to these works, we can deduce that mutations in MUA morphology are linked to: (i) Behaviour related to the nature of economic activities; (ii) Impact of regional economic growth on spatial structure (income per capita, land costs, economical sectors: primary, secondary and tertiary); (iii) Human behaviour related to employment localisation (nearest jobs, furthest jobs); (iv) Commuting patterns (radial, localised or dispersed trips); (v) Adopting a new lifestyle (choice of low density peripheral zones, presence of various services...).

Works on functioning

In his work on mobility, Appert (2004) stipulates that metropolitan processes influence the urban perimeter with intensification, lengthening and complexity of mobility. Intensification of mobility means concentration of flows due to centripetal forces. This intensification is possible for a single pole or a set of poles, so it concerns the two spatial models of centralized concentration and decentralized concentration. Complexity of mobility is perceived for decentralized concentration, there are at the same time radial, local and dispersed trips. Lengthening of mobility means that distances increase due to dispersion and urban sprawl as well as the presence of centrifugal forces which divide urban system components.

In their work on forms of relationships between poles, Schwanen *et al.* (2001) distinguish four Dutch built-up areas supposing the morphological configuration around a major centre: centralized, decentralized, cross commuting and exchange commuting. We are interested only on the two first models; centralized model corresponds to centralized concentration because there is a strong link between the major centre and the territory. Decentralized model corresponds to decentralized concentration because there are strong links between all urban poles even secondary.

Also about relationships between poles, Champion (2001) distinguishes three formation modes of polycentric urban areas: centrifugal, incorporation and fusion. The first mode is the emergence of secondary centres in urban area initially monocentric. The second mode indicates sprawl of the main urban centre which integrates small other centres to form a stronger area. The third mode signifies that many centres creating an individually attraction area, conglomerate in unique urban area.

Additionally, Bertaud (2004) defines four patterns: monocentric, polycentric, urban village and composite. The urban village pattern is utopian, an autonomous community will emerge

around employment poles allowing short displacements and use of alternative modes (walking and biking). This model could not exist because it does not actually correspond to MUA organisation which obeys to logic of economic scales. The monocentric pattern corresponds to centralized concentration model and it's characterised by concentration of activities and flows in centre, high densities, public transport use, continuous growth and radial transport system. This pattern is organised because main flows converge to the centre.

The polycentric pattern is characterised by several sub-centres without major centre, repartition of activities uniformly, medium and high densities, individual and public means of transport, discontinuous growth and random displacements. This pattern is unbalanced because flows are random and don't converge to a single centre.

In terms of activities, densities and sub-centres, this pattern may correspond to decentralized concentration. Conversely, it may correspond to decentralized dispersion because of random trips and discontinuous growth. The composite pattern corresponds to decentralized concentration and it's characterised by the presence of a major centre and sub-centres. It is unbalanced because the primary and secondary flows are both radial and orbital. It represents the current model of MUA organisation.

Generally, these works have allowed us to note that decentralised dispersion is a disorganised or unbalanced model which is characterised by random trips and lengthening mobility. Both public and individual transports are used here.

Mobility in the decentralized concentration model is intense or complex. Urban centres even secondary have strong links thanks to decentralization process. This disorganised model adapted to individual and public transports, is formed with centrifugal and incorporation modes.

Centralized concentration is an organised model. A strong link exists between the major centre and the rest of territory provoking mobility intensification. Theoretically, this spatial model is characterised by the use of public transports only. Nevertheless, Simmonds and Coombe (2000) explain that this model does not reduce the number of car trips, traffic increases at the centre of area generating a serious problem of pollution and congestion and decreases in the rest of the territory. The centralized concentration of employment pushes commuters to use more and more automobile in order to go to workplaces. However, the concentration of residences along public transport lines permits to reduce distance made by car thanks to the increase of public transport distance and the parking politic in park-and-ride.

From another standpoint, centrifugal model allows the passage from the centralized concentration model to the decentralized concentration model. In other words, the monocentric reading of urban dynamics is less and less pertinent (Heikkila *et al.*, 1989) because monocentric structure of big metropolises has tendency to dissolve over time in a polycentric structure, and it is related to the increase of urban area size.

Synthesis

Table 2 recapitulates the characteristics of MUA using the main explanatory factors.

Evolution of MUA according to the centrifugal mode

In this section, we have to take again spatial structures formation modes and especially the centrifugal mode. According to the factors cited above, we attempt to give two progressive drawings operating with decentralization phase and which illustrate creation of clusters and the development of secondary polarities like village centres and small cities (figure 7). These village centres and small cities have constituted the major elements of a rural framework which had been penetrated by the metropolitan urban system, particularly when they occupy a strategic location near major traffic lines. It is the case of Dijon urban area whom its towns and environs have become employment poles thanks to their demographic and economic growth and their situation near transport networks (Prost, 2001).

The first drawing explains the evolution of centralized concentration to decentralized dispersion passing by sprawl of metropolitan centre and formation of clusters. One of the particularities of this drawing is to tender toward a progression of decentralized dispersion (sprinkling on rural space).

Table 2. The characteristics of MUA

Spatial structure/ Factors		Centralized concentration	Decentralized concentration	Decentralized dispersion
Morphology	Population	Concentration of population in region Centralization of people at metropolis	Decentralization of population at metropolitan level	Decentralization of metropolitan population Deconcentration of regional population
	Employment	Centralization of employment	Centralization of employment at metropolitan level	Decentralization of employment
	Economic activities	Concentration of economic activities in metropolis Vertical spatial disintegration	Concentration of economic activities at metropolitan level Vertical or horizontal spatial disintegration	Decentralization of economic activities Partial or complete horizontal disintegration
Functioning	Home-work trips	Radial trips	Radial and localised trips	Dispersed trips
	Migrations	Migrations toward the metropolis	Migrations toward the metropolis	Migration from the metropolis to the non-metropolitan part
	Transport means	Publics (usual) and individuals (less frequent)	Publics and individuals	Publics and individuals
	Relational models	Organised model	disorganised model	disorganised and unbalanced model

The second drawing explains the evolution of centralized concentration to decentralized concentration specifying that the crossing between transport networks is the support of new agglomeration. It encourages urban renewal and tenders to the efficient management of space. It also clarifies that population and daily services are concentrated in secondary polarities which are characterised by the presence of transit station offering speedy access to metropolitan centre. The economic aim of this organisation is to have a dynamic link between metropolitan centre and secondary polarities. At environmental scale, this organisation proposes an answer to urban sprawl and decreases the individual transports incidence.

In addition, we can with this progression logic explain at the first step the widest range of small cities (3000 to 20000 inhabitants); at the second step their integration to urban framework with different entities: agglomerations, urban areas and employment zones (according to INSEE); at the third step their diverse identities: industrial pole, residential pole, etc.

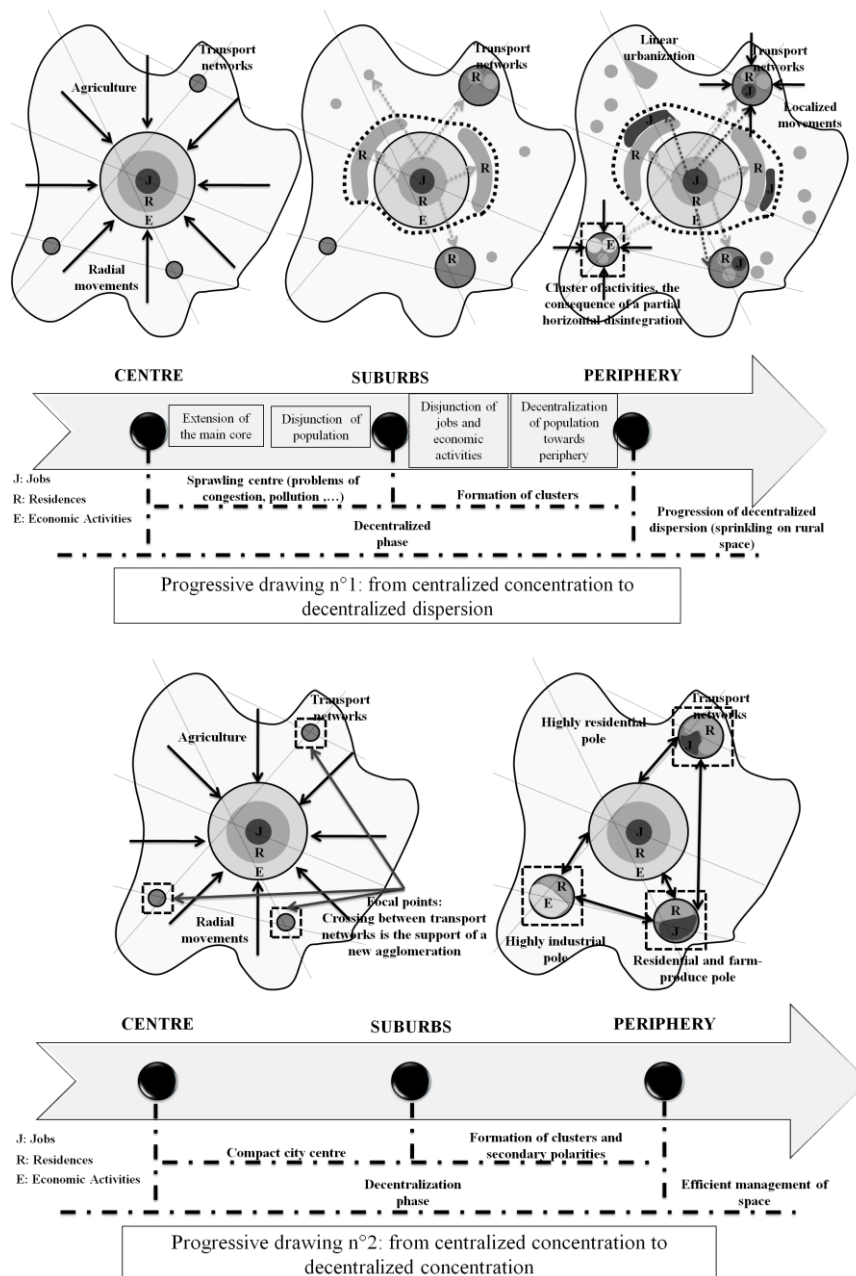

Figure 7. The drawings of MUA evolution.

The metropolitan territory of G10, towards decentralized concentration model

This section is primarily based on the urban project 'Reims 2020' presented during the conference held on December 2010, at the congress centre of Reims. The main goal of this project is to make Reims (French compact city) a reference in terms of sustainable urban development while opposing to urban sprawl and frequent use of automobile. In order to understand the philosophy of this urban project, we have chosen the proposition made by Philippe Panerai¹⁶⁴ team named Reims '2020–2050'. Their reflexion is ported on the whole metropolitan territory going from global scale (G10) to local scale (districts and polarities).

¹⁶⁴ Philippe Panerai is a French architect and town planner. Two others professional teams had participated in the project: Bruno Fortier and Christian Devillers.

With a surface of 17370 km² and more than 1 million inhabitants (80% in urban space and 20% in rural space), the G10 is situated in northern France and concerns three departments (La Marne, L'Aisne and les Ardennes). It's a heterogeneous territory which has a specific and unique geographical configuration in both national and Western Europe levels. Effectively, it represents ten cities situated in a radius of 50 kilometres without conurbation and concurrence, functioning in a good coherency: Laon, Soissons and Chateau-Thierry localised in the Picardie region; Epernay, Chalons-en-Champagne, Vitry-le-François, Rethel, Sedan, Charleville-Mézières and Reims localised in the Champagne Ardenne region. These cities are served by rail and road networks in a star configuration (1 hour maximum for a trip on the railway between the ten cities of G10) (figure 8).

Figure 8. The configuration of the G10 (source: Panerai et associés, 2009).

It is important to note that the G10 is a territory of exchanges based on economic and social relationships; Reims purposely constitutes the metropolitan centre of G10 because it centralizes several exchanges with the nine other cities. Table 3 illustrates population repartition on the G10 territory.

Table 3. The population repartition on the metropolitan territory (source: Panerai et associés, 2009)

Metropolitan territory	Demography
Reims area	2888000 inhabitants
G10 cities (without Reims)	381000 inhabitants
Metropolitan G10	600000 inhabitants
G10+interstitial space of villages and small cities	750000 inhabitants
Departmental G10	1,13 million inhabitants

INSEE (2012) had studied privileged relationships between the cities of G10. In this study, we have understood the general function of the metropolitan urban area which is characterised by framework structured according to centralized concentration:

- At the migratory level, Reims centralizes 70% of residential movements between G10 cities and attracts more and more young people. We can explain this residential attraction by the presence of Reims University as regional and interregional infrastructure that offers higher education. Rethel is the only attractive city for people of Reims because of availability and low

costs of land as well as the existence of speed transport to Reims. Other interdependency links can be highlighted such as Sedan and Charleville–Mézières, Soissons and Laon, Vitry–le–François and Chalons–en–Champagne.

- Concerning commuting, Reims concentrates 60% of trips principally with the seven nearest cities. These exchanges are as the whole equilibrated except those of Epernay and Rethel with Reims. Effectively, many people of Reims go to work in Epernay whereas people of Rethel are more oriented to Reims. Other favourite links exist between nearby employment zones related by a major road: between Charleville–Mézières and Sedan (equilibrated exchanges), between Soissons and Laon (equilibrated exchanges), between Vitry–le–François and Chalons–en–Champagne (unbalanced exchanges). Less important links exist also between Soissons and Chateau–Thierry, Chalons–en–Champagne and Epernay.

- At the economic level, Reims centralizes corporate headquarters occupying an important place in the economic fabric of G10 (especially financial activities and insurances). Economic links exist between Sedan and Charleville–Mézières in sectors of commerce and real estate business, between Rethel and Reims in rubber and plastic products industry, between Reims, Vitry–le–François and Epernay in the food industry.

INSEE is predicting from 2030 negative natural increase and migration balance in Champagne Ardenne as well as negative migration balance more important in Picardie. However, this demographic decrease will be accompanied by a significant increase of households and housing needs. In order to thwart this situation favouring G10 configuration and thinking about polarities organisation, Panerai team proposes the concentration of demographic growth in metropolitan level rather than continuing urban sprawl (figure 9): 60000 additional inhabitants in G10 cities (10%) and 8500 additional inhabitants into the space of villages and small cities, so, 668000 additional inhabitants (11, 5%) in G10 in 2050. According to decentralization process, this growth is moderate because development will operate in urban poles without Reims city (population would pass from 87% to 78%) whereas Reims metropolis in G10 would know demographic gains (population would pass from 36% to 39%). Housing offer and metropolitan network development would be added to this decentralized concentration. So, metropolitan concentration will be accompanied by decentralization of population.

Figure 9. The Panerai sketch (source: Panerai et associés, 2009).

For checking sustainable mobility and decreasing car trip number, Panerai team proposes many ecological measures such as development of express regional train, complementarity between transport networks, setting of rapid buses, access facility to alternative modes and harmonisation of transport pricing.

Finally, the set of these measures tenders to settle decentralized concentration at metropolitan scale and aims to equilibrate flows, increase Reims and G10 attraction, establish

equilibrium between urban and rural space, attract people to come from elsewhere (Paris, England, Canada) and avoid Reims polarization.

Conclusion: towards a more sustainable future of MUA

In this paper, we have tried to demonstrate morphology and functioning of MUA employing theoretical and multidisciplinary approach. This approach is situated in a favourable context for studying the complex processes that accompany metropolisation phenomenon. Effectively, 'morphologies and intern functioning of French metropolises of 2040 would be the spatial result of production systems and exchanges transformations as well as political choices that would have determinate or accompany these transformations' (DATAR, 2012).

All documents studied have allowed us to define the four metropolitan processes (concentration, dispersion, centralization, decentralization), then to elaborate synthesis with a recap chart to obtain a new spatial typology. The objective has consisted to make sense to spatial models with a set of factors pulled from the works of many Francophone and Anglo-Saxon researchers. Factors have been presented in two groups, those in relation with morphology and those in relation with functioning. This list of factors is not exhaustive and varies according to the contexts and planning policies of each country.

Centrifugal evolution of models and general characteristics stemmed from theoretical development have been presented with table and illustrations. We note here that progressive drawings look like to logical explanations of Parr who has confirmed that income increase, transport development and land availability are the most important parameters of decentralization of people and activities as well as the increase of dispersion tendency.

Since reflections on the future European city highlight more and more polycentric and multi-polar forms (Wulfhorst *et al.*, 2007), we defend therefore the decentralized concentration as the ideal spatial model of MUA. It would be necessary to long term to opt for a planning more compact based on transport nodes. These nodes represent an interface places conciliating both urban form and connexion with the territory. Furthermore, decentralized concentration with a political voluntarism could play an important role in space hierarchy and the consolidation of the secondary polarities role in metropolitan space.

The city, the river and mangroves: a case study in São José, Santa Catarina, Brazil.

Érica Corrêa Monteiro, Raquel Weiss, Guilherme Antônio Barea

Post-Graduation Program of the Architecture and Urbanism Department, Federal University of Santa Catarina. E-mail: ericapaulaarq@yahoo.com.br, rwarqui@hotmail.com, arq_barea@hotmail.com.

Abstract: *Brazil is among the countries with more mangrove areas, with approximately 25,000 km², representing approximately 12% of mangroves worldwide. For this article, is taken as the study mangrove located in São José in Santa Catarina, Brazil, whose influence growth and urban interventions for improvement in this area, without considering the importance and dynamics of mangrove witness significant environmental impacts and accelerated process of disappearing arising from these changes in recent decades. Thereby, the work seeks to diagnose and analyze the impacts of these dynamic processes, considering physical, environmental, economic and social aspects. Through employee photo interpretation techniques, creation of GIS (Geographic Information System), time series and geoprocessing techniques. Firstly, it takes advantage of a more global scale, which aims to highlight the potential that the area has with its surroundings, using principles of landscape ecology as a means of integrating the systems that make up the area. In a second step, it works in a larger and more detailed scale photographic surveys along with the implementation of municipal courts, in order to understand the dynamics and urban structure. Thus it'll be possible to diagnose and extract important information that underpins strategies to conserving or restoring this mangrove.*

Key Words: city; river; mangrove; impacts; conservation

Introduction

Brazil is among the countries with more mangrove areas, with about 25,000 km², representing approximately 12% of mangroves worldwide. Comprises a territory that extends from the state of Amapá, north, to south in the state of Santa Catarina, more precisely, to the city of Laguna (Vasques et al., 2011).

Mangroves configured in unique environments as they present themselves as a coastal ecosystem that develops along estuaries, bays and lagoons, a result of the meeting of sweet and salt waters. Thus, it is composed in a medium containing brackish water and nutrients endowed with muddy soil encourage the growth of plants species with roots and textures of plant material that partially decomposes. Due to these characteristics their own, also many animal species have shelter (Alves, 2001, Vasques et al., 2011).

Therefore, mangroves play a significant role in relation to marine life, areas of waterways that permeate the plant and animal populations that need this peculiar shelter to develop and, above all, the man who draws his vegetable resources and animals. Also promote the maintenance of coastal areas, with real shells that protect the territory of erosion from waves and tides and retention of sediments carried by the rivers (Correia and Sovierzoski, 2005).

However mangrove areas, although they are protected by specific laws, are suffering significant environmental impacts resulting from human activities, which undermine its stability, vegetation structure, fauna and significant reductions in area due to urban pressures. Are targets of deposits of solid waste, sewage, deforestation and landfills, threatening the existence of their areas and the balance of the coastal zone (Alves, 2001, Silva et al., 2005).

Problems aggravated by neglect and complacency with which the government treats such areas not complying with existing laws and not giving proper ecological and economic value that mangroves provide to citizens.

Thus, this work makes a timely analysis of an urban clipping covering the mangrove and adjacent areas located in the city of São José in Santa Catarina, Brazil, to later propose some strategies to preserve, conserve and enhance these natural spaces.

Methodology

To achieve the proposed objective, a survey of the study area, considering their physical, environmental, economic and social aspects was performed. Through employee photo interpretation techniques, creation of GIS (Geographic Information System), time series and techniques were possible to make a diagnosis and to extract important information about the existing problems (Li, 2008, Kong and Nakagoshi, 2006).

At first, the work took on a more global scale to highlight the potential that the area has with its surroundings, using principles of landscape ecology as a means of integrating the systems that make up this space. In the second stage, we worked from a larger and more detailed scale, taking advantage of photographic surveys as relevant complements the urban cuts, in order to understand the dynamics and urban structure.

Finally, these strategies we could identify measures and plausible solutions could be deployed in these areas, taking into account the ecotourism practices, accessibilities, movements of animals, people and vehicular traffic.

The city of São José

O São José is located in the east of Santa Catarina-Brazil, forming a region of conurbations, as part of what is called Big Florianópolis. It is the fourth oldest municipality of Santa Catarina, the fourth city in number of voters and the vast majority of its population is concentrated in urban area (Livramento, 2008). See Figure 1 .

Among the main access roads to the city, we highlight the BR 101 with international role.

Figure 1. Location of São José-SC and area of study. (source: Authors, 2014).

The landfill

Among the most significant areas of the city, there is the existence of a maritime strip which significant portion is derived from a process of landfill. This is configured as one of the main interventions and responsible for significant changes in the city. Named with Long Beach Landfill, its initial project dates back to 1991, undergoing a reformulate in 1995 and with the final proposal in 1998, starting his execution in 2000. Extension project was to the fillet covering the Araújo river, boundary between the cities of São José and Florianópolis, to the Historical Center. However, its implementation was partly, not reaching the old town (Silva, 2006). See Figure 2.

Figure 2. Landfill proposed (1998) (Source: Silva apud Farias (2001)).

Figures 4, 5 and 6 show terrify area in relation to the case study. We notice how main interventions the creation of Beira Mar Avenue, bike path, promenade and wide open spaces, totaling an area of 37,230.8 m².

Figure 3. Mangroves and the infrastructure around (source: Authors, 2013).

Figure 4. Panoramic landfill area and mangrove (source: Authors, 2013).

Moreover, among the main findings, it is worth mentioning the economic changes as one of the most expressive. Until the implementation of continental landfill, buildings constructed near the shore had characterized the funds as the batch tested overlooking the sea. From the process of filling, with implanted of vehicular roads, bike and pedestrian, note a new trend. Observation made from Silva, 2006: "Finally, the contact with the sea. Historically, the city of São José was built 'backs' of the sea, for even less than a century, the waterfront was considered a negligible space left for slaves and garbage houses ".

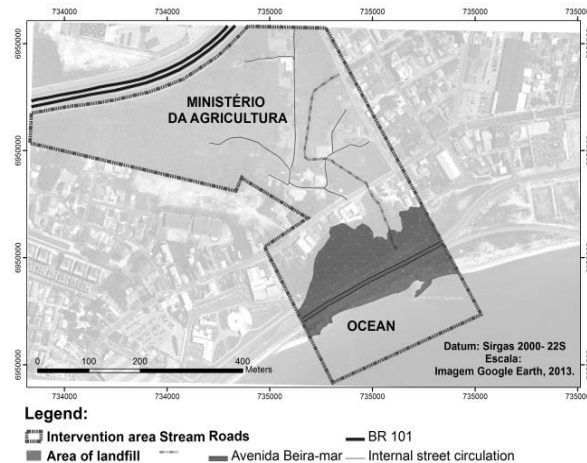

Figure 5. Landfill area in cropping study (source: Authors, 2013).

The buildings are now designing their main front for Beira Mar Avenue, endowed with significant territorial recovery and target real estate speculation. Have as main uses, institutional buildings, connected to the municipal government, and commercial. Mostly present considerable areas of occupation and significant infrastructure.

The study area

Among the areas that comprise the landfill, there is the existence of a mangrove, targeted study of this work, because of its ecological importance and its ecotourism, economic and social potential. Besides the mangrove area, was taken as part of this study an adjacent space, whose domain is the Ministry of Agriculture. These two areas form a big potential for deploying a park with a system of free spaces integrated with significant green areas for recreation and ambient quality taking into consideration your surroundings, especially when associated with Beira Mar Avenue, cycleway and the existing public footpath.

To access the study area has, to the north, the local road Jaci S. Lins and, with higher flow, the BR 101. To the south, the Beira Mar Avenue and dividing the mangrove area of the Ministry of Fishery area, Joaquim Antônio Vaz street, who is responsible for the main access and continuous flow of vehicles throughout the city. See Figure 6.

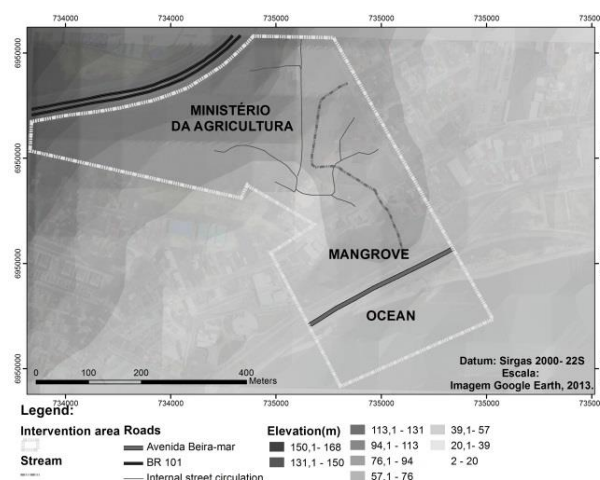

Figure 6. Hypsometry and access (source: Authors, 2013).

Art. 181 To the hydrographic elements also applies to federal competent legislation, such as, water code, forest code, decree-law 9.760/46 and notable subsequent legislation (MASTER PLAN, 2013).

However, even appears on the zoning map and uses the mangrove area and, much less, the identification of PPAs, both referring to the mangroves as the water course that comes from the Ministry of Agriculture (Figure 7). As demonstrated above, have the occupation of mangrove areas by urban buildings that gradually exert pressure, decreasing the mangrove and causing serious environmental impacts. Ironically, there are buildings of the Ministry itself that do not respect the PPA 30m of the river that passes over your area.

It should also be mentioned, among the zoning defined by the said Master Plan, in section VI, about the criteria and determinations as to municipal Green Areas (GA), establishing them as their purpose. The Leisure Green Areas (GA) should take advantage of native vegetation where it exists, to publicly consecrated areas or adjacent to community equipment. Even contained in Article 146: "The greater the GA over its location should be linked to natural factors of morphology, vegetation and aquatic elements."

And in Article 147: "In exceptional cases the Green Recreation Areas may be located within the protection zone buffer maritime margin (marine lands), subject to the provisions of the Law of Installment Land".

Forest Code

Another important conditioning is the Brazilian Forest Code, which is regulated by Law Nº 12,651, of May 25, 2012. On this contain the PPAs regulations and Urban Green Areas.

Moreover, it complements the previous article with the Art. 4º and delimits the PPAs as areas of sandbanks, as dune fixers or stabilizing mangroves, throughout its extension.

As to guarantee the protection and restitution of vegetation of PPAs, it is Article 7º that provides the stay be mandatory vegetation in such areas by the owner of the area, possessor or occupier for any purpose, individual or juridical entity, the public or private law.

In case of suppression of vegetation, it is for the owner of the area, possessor or occupier for any title, the obligation to provide the restoration of vegetation, except for the authorized uses provided for in Law (public utility, social interest or of low environmental impact hypotheses).

In Art. 9 the access of people and animals to Permanent Preservation Areas to obtain water and to perform low-impact activities are allowed.

It is noteworthy also that in Section III defines the Regime for the Protection of Urban Green Areas:

Art. 25º. The municipal government will, for the establishment of urban green areas with the following instruments:

I - the right of preemption to acquire relevant forest remnants, pursuant to Law nº 10,257, of July 10, 2001;

Confrontations: Spatiotemporal analysis x national and municipal laws

To better understand the studied space, was made a spatiotemporal analysis considering three periods, based on aerial and satellite images of the years 1957, 1978 and 2013, in order to identify the urban dynamics and processes of expansion. The following figures show the evolutions of study area and allow you to make some considerations.

When conducting an analysis from the current situation based on old information about the area, it is noticed that today, although mangroves are protected by laws of national and municipal level, their protection and maintenance have been negligence by Municipal authorities, as the population living around it. Residential buildings and primarily commercial occupy part of mangrove, bringing significant environmental impacts arising from the construction area in last decades. These exert pressures on mangroves, progressively reducing its length, as well as being responsible for pollution, dumping of waste and sewage that

compromise the vitality and expansion of mangrove and, thus adversely, affect the flora and fauna characteristics of this habitat, such as crabs reproduction, numerous species of fish and bird feeding. See figures 8, 9 and 10.

Figure 8. 3d use and current (source: Authors, 2013).

Another problem identified was the construction of traffic lanes, of the Beira-mar (coast), in the mangrove area only with the opening of two channels that allow the passage of salt water (sea) reaching the mangroves and vice versa. However, this passage is insufficient to ensure an environment of salinity along the water of the river, as is relevant to the vitality of the same process. See Figur.

Note that, by law mangrove areas should be protected and preserved. However, with the urban dynamics and disorderly occupation, we find several residential and commercial occupations settled in the mangrove area that, over time, were being cleared and paved. See figures 12 and 13.

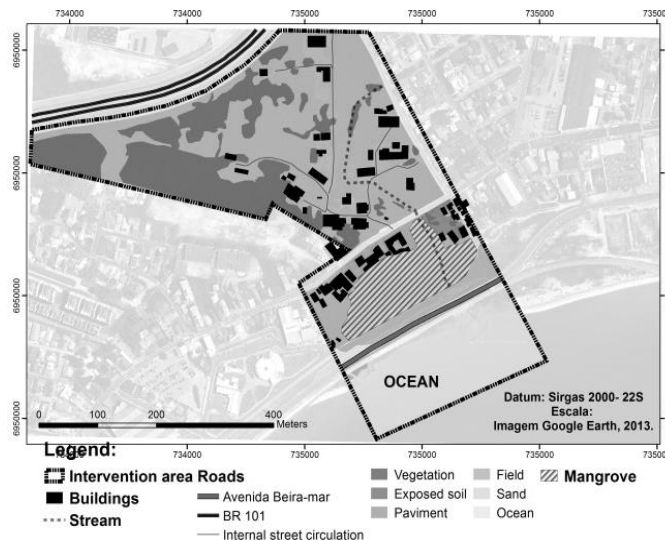

Figure 9. Use and occupation 2013 (source: Authors, 2013).

Figure 10. Panoramic showing occupation of mangrove área (source: Authors, 2013).

Figure 11. Openings for passage of seawater to mangrove (source: Authors, 2013).

Figure 12. Map of the mangrove and inadequately occupied areas (source: Authors, 2013).

Figure 13. Land use 2013: Area (há) (source: Authors, 2013).

In the watercourse that runs to the mangrove there is disrespect for PPAs, whose Forest Code establishes as 30meters protected area not edifying, when the river has a width of up to 10m. Therefore, the illegalities occur most significantly in the field of the Ministry of Agriculture, where only 27% of PPAs have vegetation cover, which is more significant because of the

mangrove. Of the remaining 73% are disrespected and comprise field, exposed soil and paving. See figures 12, 13 and 14.

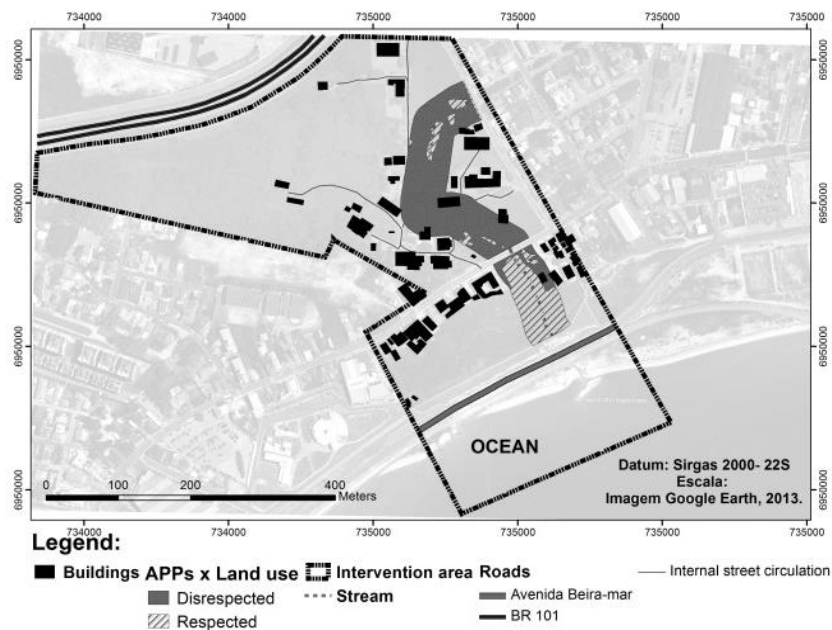

Figure 14. PAs x Uses (source: Authors, 2013).

Figure 15. Land use 2013 x PPAs: Area (m²) (source: Authors, 2013).

By analyzing the use and occupation of this area in 1978, it is noticed that the coastline had its threshold along the Joaquim Antônio Vaz street. In its entirety the cut consisted of field and some fragments of vegetation. The fragmented mangrove area was permeated by a sandbar. Since that time, there were irregular buildings in mangrove areas contravening existing laws. See figures 14 and 16.

Taking the last review period, the year 1957, it is observed that it was during this period that most of the buildings belonging to the Ministry of Agriculture were built. In this sense, the deployment area is characterized as vast green fields together some fragments of vegetation and presence of exposed soil area between the buildings. It is noteworthy, too, that in this period there was no appropriation of the mangrove area where their boundaries were demarcated by

Joaquim Antônio Vaz street. See figures 15 and 19.

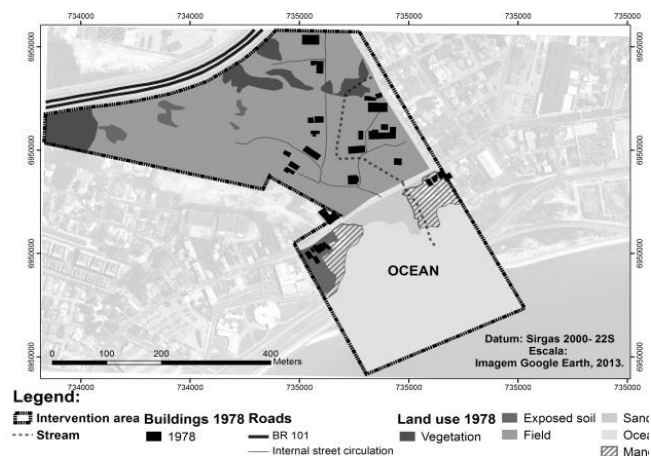

Figure 16. Use and Occupancy 1978 (source: Authors, 2013).

Figure 17. Land Use 1978 - Area (há) (source: Authors, 2013).

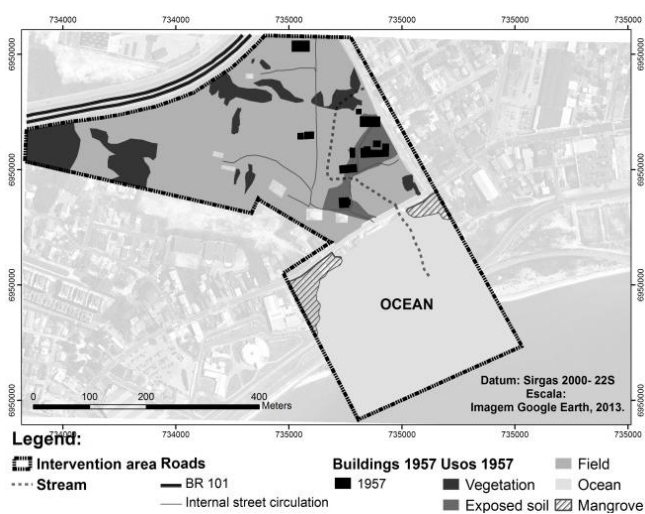

Figure 18. Use and Occupation in 1957 (source: Authors, 2013).

Figure 19. Land use 1957- Area (há) (source: Authors, 2013).

Thus, from the analysis of space-time is possible to diagnose it over the course of years the mangrove area increased, but being isolated in the urban area, because the processes implanted landfill. The occupations began in 1978 and had its intensification in later decades. Another unusual fact, by the reality experienced by most cities, is on the increase in areas with vegetation cover and areas of exposed soil before becoming field. See Figur.

Figure 20. Analysis of alterations 1957, 1978 e 2013 (source: Authors, 2013).

Final considerations

Seen the importance and training of an ecosystem with its own characteristics, which are essential to develop projects and initiatives that establish the revitalization, sustainable use and, above all, compliance with national and local laws concerning the guarantee and protection of mangrove areas.

Thus, as a first consideration on existing laws would propose the eviction of houses and illegal trades of PPAs. In this sense, interventions begin by recuperation of these areas and recovery of these environments by means of specific actions for integrating these spaces as a whole.

As mentioned earlier, with the implementation of the landfill were reduced flows along the saltwater marsh. Therefore, it is necessary to increased permeability, with more openings for channeling water to enable the passage of seawater and thus introduce again the relation of tidal flows that pervade the vital functions of mangrove areas, forming a large lake with direct influence, returning it an environment of high salinity, essential for the development of vegetation.

According to Alves, (2001) and Silva et al (2005), the mangrove has essential role in the dynamics of the estuary areas, with a space of sedimentation of the material carried by the rivers and sea. Such an environment enables the development of vegetation with protruding roots that perform the fixation of the transported material. This process contributes to increasing the shoreline and an increased range of vegetation.

The typical vegetation for mangrove area, in this process, is predominant, because when you enter the front lake for a direct influence of the waters to mangroves, makes you create a transition band from an environment that has changed, again, vulnerable. In this case, it is essential to implement vegetation typical of mangrove protection as, for example, the Praturá-grass, considered a marine grass genus *Spartina*, that functions as a protection filter estuary areas that can remove pollutants and heavy metals. Consequently, ensuring the survival of mangrove vegetation typical, there will be the development and diversification of animal species such as crustacean, fish, crabs and resident and migratory birds. For (Costa, 2006), these animals make use of that space for shelter, means of reproduction, growth and maintenance.

Besides the mangrove area is interesting to note that the strong relationship of the river on the area of intervention is present in its entire hydrographic contour. Thus, it is necessary to deploy along the river lakes openings to improve the flow and the flow right next to its utilization for environmental system.

Among the aspects to be considered, there is fragmentation of green open spaces. These, mainly result from appropriations and anthropic pressures exerted by the urban expansion. According to Collinge (1996), fragmented green areas lead to the configuration space in a kind of island, whose striking factor is the loss of biodiversity, because it ends up isolating animal species and vegetables and favors the invasion of exotic species. Moreover, it contributes significantly to the deterioration of vegetation along the waterways, compromising the quality of it and making it areas susceptible to processes of sedimentation and erosion.

Thus, it is necessary to seek the revitalization and preservation of existing large green areas, as well as the creation of new and restoration of riparian vegetation along the streams, in order to requalify spaces, provide them with environmental quality and ecosystem balance (Collinge, 1996, Gurrutxaga et al., 2010).

Among the main mechanisms of intervention and minimize these impacts there is the use of techniques related to landscape ecology, more proper, the use of ecological corridors. Responsible for reestablishing the connectivity of fragmented areas, play important for quality of life, especially in a city, since they allow the spread of animal and vegetation, are configured in the lungs of urban spaces and promote spaces for recreation and appreciation to the surrounding populations (Chang and Chao, 2012, Kupfer, 2012).

Another relevant to the recovery of the mangrove area strategy would incorporate it into the daily life of local people and highlight their tourism potential. Thus, the value of social appropriation could be experienced through the creation of public open spaces, insertion of trails, viewpoints and park paths that circumvent the mangrove and the river banks, providing opportunities for collective living, leisure and enjoyment, tours, rest and contemplation of protected areas, and especially knowledge about this peculiar habitat.

In response, it intensified the need for intervention projects for mangrove areas along the areas of the Ministry of Agriculture, in order to adapt their environmental potential with beneficial actions and proposals that foster local identity, the connection between the Management and the environmental issues inserted in the urban environment.

It is a complex and necessary process, whose transformations arise from the direct relationship between Management and population as an essential source of care and

understanding of the importance of this habitat to the city, because it takes better care of what one knows and loves.

Urban growth and hydrography: convergences on landscape morphology

Otávio Peres, Mauricio Polidori, Marcus Saraiva, Alexandre Santos

Laboratory of Urbanism, Faculty of Architecture and Urbanism of the Federal University of Pelotas, Brazil. E-mail: otmperes@gmail.com, mauricio.polidori@gmail.com, marcus.saraiva@gmail.com, alexandre.pereira.arq@gmail.com.

Abstract: *This work identifies the relationships between urban morphology and natural landscape as a result of urban growth articulated to the spatial scale of hydrography based on the assumption that in the long-term and in macro spatial scales city and environment could reduce spatial conflicts. The main focus is to outline an urban growth dynamic articulated to natural landscape in which water resources are understood as tipping point to phase transitions in urban growth morphologies. This theoretical statement is applied in the urban growth simulation framework CityCell through the potential-centrality model in a dynamic cellular automaton. The urban modelling mechanism captures the "edge effect" on water resources buffers, parametrically distributing urban growth in axial and diffuse tensions. Associated with urban modelling, the theoretical statement was empirically tested in simulations, replicating the urban growth reality of the city of Pelotas, RS, Brasil for the period from 1815 to 1965. In the framework of systems theory, by empirical, theoretical and methodological approaches, the urban modelling results can be replicated in future urban growth simulations, especially to study the relations between urban form and natural landscape.*

Key Words: urban growth; hydrography; cellular automata; city edges; urban systems

Introduction

Traditional approaches in landscape planning have difficulty to address city dynamics and natural environment based in their mutual influences. Traditional ideas of urbanism performed structural interventions on water resources in order to drain and clean up the environment; thus enabling the process of urban expansion on behalf of the compact city (Jenks e Burgess, 2000). On the other hand, environmental planners suggest water resources as structuring urban growth process based on idea that urban waters are vital to sustaining human life on the planet. (Alberti *et al*, 2003).

Approaching urbanism, urban ecology and landscape ecology, in a broader framework, environmental science paradigm is on articulated urban form and urban growth studies on natural landscape support. Thus, urban science will be applied to better understand compatibilities of urban form with natural environment and water resources system.

Supposing city as a complex system, with urban form emerging in different spatial patterns, this paper aim to identify urban form relationships with natural landscape scales defined by hydrography

This work suggests a space-time convergence between urban growth morphology and landscape scales defined by hydrography. The main contribution is a theoretical statement that describes a urban growth dynamic that occurs alternating concentric and diffuses external morphologies spatially oriented by hydrographical formations.

In this sense, assuming that natural landscape would able to support urbanization in different spaces, urban growth dynamics defined by compression and fragmentation movements would be spatially articulated with water resource's environmental fragilities and urbanization resistances.

Theoretical Approaches

Ecological Approach: emergence, self-organization and urban resilience

Analogies between Urban systems and ecological systems were first applied in urban science by Chicago's school authors (Park e Burgess, 1925). These authors were based on ecological theories, as cooperation and competition mechanisms, to better understand intra-urban organization forces able to leave the urban phenomenon in a socio-spatial order.

Differently, today there is a consensus that, precisely, these competition and cooperation mechanisms that keep urban system in constant imbalance. In times that simultaneously ecology and urbanism starts to investigate the balance breakdown, as a way to maintaining internal vitality and dynamics, intrinsic features in respective systems (Alberti, 2003; Forman, 2008; Marzluf, 2008).

Contemporary, urban ecology's paradigm are systems theory and self-organization sciences, with common concepts in natural science and social sciences, indicating the city as emergent phenomenon. Until the mid-20th century, complex structures as cities were assumed ignoring the overlapping high degree and randomness that occur in their subsystems (Portugali, 2000; Alberti *et al*, 2003; Buzai, 2003). Currently, there is a change in cities and societies approaches, like complex organisms that continuously grow and its modifications can only be focused, induced and rarely designed in top-down sense. In urban science, it has been assumed its urban growth as an emergent phenomenon from thousands agents action, resulting in a complex structures behaviour (Batty, 2007; 2013).

Urban self-organization studies has indicated cities as the largest human action artefact (Portugali, 2000) and over 3,000 years of history show that must withstand throughout time (Vale and Campanella, 2005). From this viewpoint, urban sustainability is associated with intrinsic properties as a complex phenomenon which gives it self-organizing and resistance abilities through times. In complex sciences, self-organizing structures are able to handling in adverse situations, which in urban ecology has been referred in terms of urban resilience (Alberti *et al*, 2003; Vale and Campanella, 2005).

In this sense, urban form self-organization proprieties are not associated with geometric arrangements (such as it occurs in other complex systems), however urban sustainability are discrete structural properties shared by cities in resilience terms (Portugali, 2000).

Urban theories, growth dynamics and natural landscape convergence

In short and recent history, urban science has explored the urban phenomenon through models and theories (Batty, 2013).

Urban growth has been studied since pioneers locational theories, until mid-century XX, where several authors have attempted to explain the city based on cause-effect logic, from a single viewpoint: ecological, economic or social. Recent statements have approached city growth as complex systems and self-organization theories framework, and even more contemporary, approaches about urban form discontinuity and convergences to natural landscape. (Batty and Longley, 2004; Czamanski *et al*., 2008; respectively).

The first urban locational theories launched in later XIX century by von Thünen, based on profit maximization economic principle are replicated in Alonso's monocentric city model (1964, Figure 1a). A disc-shaped Central Business District (CBD) and surrounding residential region served as a starting point for urban model analysis.

A concentric urban model was also associated with ecological logic by the Chicago School (Park and Burgess, 1925 Figure 1b) and later related to accessibility in Hoyt's sector model (1959, Figure 1c). Also, the city concentric thought was proposed by Christaller (1933, figure 1d) in Central Place Theory, differing by regional scale approach and polycentric occurrences.

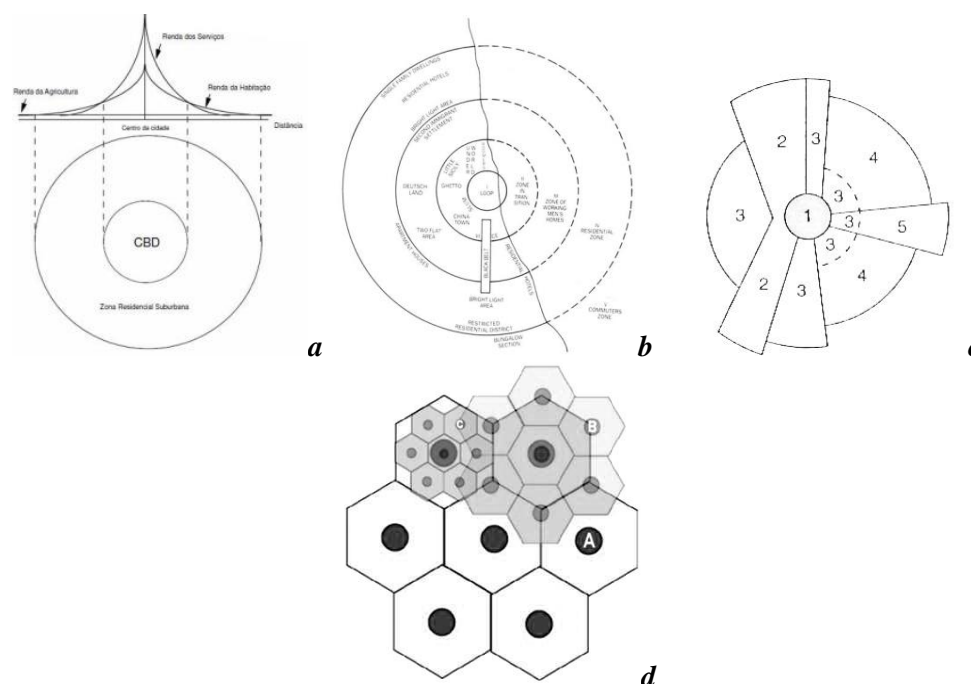

Figure 1. concentric urban models:
a) Alonso, 1964; b) Park and Burgess, 1925; c) Hoyt, 1959; d) Christaller, 1933.

However, these primal urban locational theories were unable to describe the urban growth dynamics and temporal approaches, mainly by static configurations. These important theories are replicated in contemporary geographers and economists studies, authors like Fujita and Mori (1997), in complexity framework, featuring the New Economic Geography theoretical approach (NEG). The "evolutionary approach to urban systems" (Fujita and Mori, 1997) suggests the urban theory validity from a evolutive approach, relating it to Darwin's evolutionary process. From NEG evolutionary approach, researchers such as Janoschka (2002) have (has) been explaining successfully the spatial discontinuity and the suburbanization phenomenon in Latin American cities. These works have (has) been supported by dynamic resummptions of classic locational urban theories, a evolutionary-historic read about Alonso's, Hoyt's, Park and Burgess' and Christaller's models (illustrated in Figure 1, above).

Currently, more studies dedicated to external urban growth dynamics and the correlated morphological fragmentation are produced, with recent studies with natural landscape scales integrated into urban approaches (Czamanski *et al.*, 2008). In this way, after featured studies on urban sprawl and fractal dimension of Tel Aviv, Benguigui, Benenson, Czamanski, Portugali and others researchers from the Research Lab Complex City (<http://www.eslab.tau.ac.il/>) have achieved important advances in theoretical approaches to better understand urban spatial discontinuity, specially associated with a growth dynamic called leapfrogging. (Benguigui *et al.*, 2001).

Leapfrogging originates in a child's game to perform jumps driven by obstacles over other child. This theoretical approach has also been absorbed by economic theories to approach economic growths in unfavourable situations by innovation actions.

Urban growth associated to leapfrogging ideas corresponds to an urban morphology dynamic able to set up successive open spaces, similar to fractals geometries and urban sprawl theories. Thus, urban spatial discontinuity may be explained by articulation with landscape fragilities or environmental value, thereby reducing the urban footprint effects (Czamanski *et al.*, 2008).

In a recent editorial for Environment and Planning: B, Batty (2009) presents the catastrophic cascades idea, which proposes a challenge to contemporary urban theory. The challenge to

studies about urban change and dynamics should be to extend our understand of discovering discrete subsystems that catalyze the dynamics through a called catastrophic cascades. According to the author, urban dynamics derive from multiple attributes overlaid that are able to influence the global order and urban spatial discontinuity. These multiple attributes associating economic, social and environmental issues, shape the urban morphology in a complex way and enable triggering abrupt changes on urban dynamics. In this work Batty proposes a challenge to urban science, that is in overcoming studies to indentify attributes that composes urban system as a complex system. Contemporary urban studies should be applied to identify the tipping points where occurs the transition phase in convergence with all the system.

However, for effective integrated approaches between city and environment, we should overcome traditional ones based on isotropic plain assumption (Nystuen, 1968). The landscape isotropy concept is an abstraction of the environment, widely applied in classic urban theories, which disregards urban landscape aspects where the natural environment does not provide any kind of resistance to urban growth.

In fact, natural landscape represents the predecessor environment around the city, operating as an irregular field exerting different resistance intensities. Natural landscape directly influences the morphology of urban growth in the short and long term, both at micro as at large scale. (Polidori, 2004).

The landscape irregularities are able to impose greater or lesser restrictions on urbanization, and hydrography attributes assumes a crucial role in landscape shaping. Rivers, streams and drainage lines feature places usually flooding, in general unhealthy and the land has low capacity to urbanization. Moreover, on hydrography natural scales, watershed ridge lines are generally places for local environmentally friendly urbanization. Ridge lines are in essence the higher locations in a basin, with better drainage and usually away from challenges imposed by drainage adjacent areas.

Urban Growth and Hydrography: empirical approach to Pelotas case [1815-1965].

Pelotas is a city located in southern Brazil , on state of Rio Grande do Sul (RS). In the UTM coordinate system (Universal Transverse Mercator) is located in zone 22 south, 373,081 meters at east and 6,482,330 meters at south.

In southern Brazilian cities the water systems - rivers, lakes and ponds - were decisive factors in land-use process. The low altitudes, slopes and wetlands in abundance configured a landscape of difficulties to urbanization and displacement on territory (Souza, 2000).

Specifically in Pelotas region, natural landscape attributes were dominant in the urbanization process. This area was found as undeveloped and appropriate to implement a salt meat process called *charqueadas*. At the end of the eighteenth century the *charqueadas* were attracted to the region by possibilities of disposing the production and the waste by water ways (Gutierrez, 2004).

For the first urban core location, in 1815, was chosen a shortly elevated terrain to run off water and better drain the streets. From original core, in 1835, a concentric second plan to expand the city was (Weir) located yet on slightly elevated terrace. As it is shown in figure 2 below, this plan expressly avoids the low areas along water resources, places with constraints to urbanization.

After this period, the city maintains concentric growth morphology urbanizing low areas next to water resources.

Occupying wetlands adjacent to streams, at same time, allotments occur in small scale and diffused on landscape. At this time, urban growth morphology occurs beyond limits defined by water resources and located on terraces adjacent to watershed ridge lines (Gutierrez, 2004).

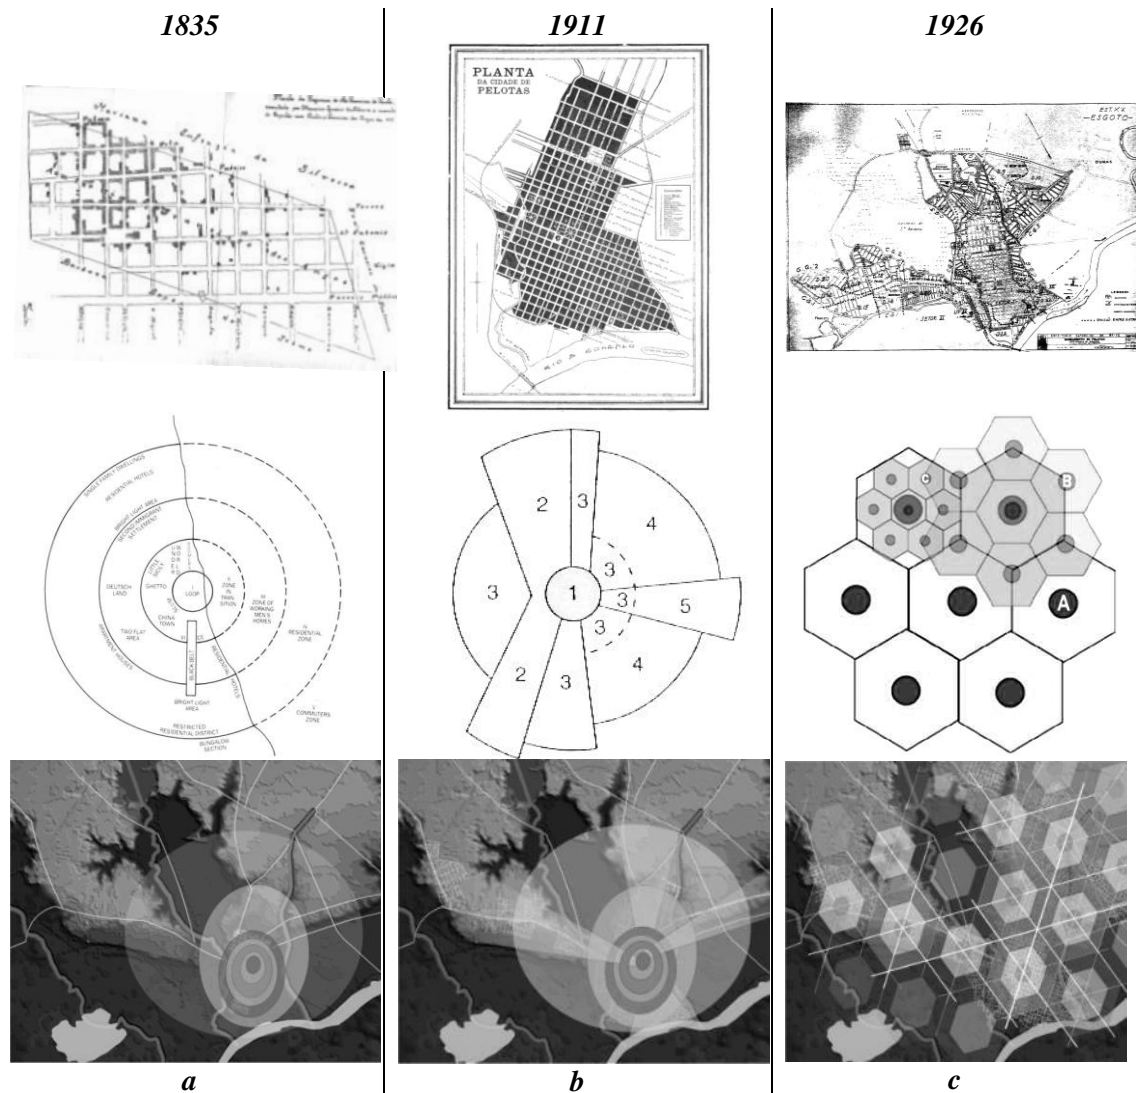

Figure 3. table showing theoretical convergences between "evolutionary approach to the classical models of urban theory" and urban growth stages of Pelotas city:
a) 1835 x concentric model; b) 1911 x sectoral model; c) 1926 x multi centralities model.

This outcome suggests recognizing urban voids as structural city component and urban morphological changes convergent to natural preservation. Urban growth forms articulated with hydrography can be understood as a mechanism for city self-organization, giving it ability to sustain through time. (Alberti et al., 2003; Polidori, 2004).

Urban Modelling Approach: urban growth simulation in a CA context.

As urban growth methodological approach this work assumes the spatial differentiation possibilities of Potential-Centrality Model (Krafta, 1994). Originated from Uneven Geographical Development theory (Harvey, 1985), Krafta's Potential-Centrality model enables to approach the urban loads over urban space representing the system into a imbalance spatial state.

From original Potential-Centrality Model statement (Krafta, 1994) a continuous research has been developed to improve city comprehension by production and reproduction of internal

mechanisms. This efforts have been undertaken by Configurational Urban Systems Group in Graduate Program in Urban and Regional Planning, PROPUR-UFRGS and in Graduate Program in Architecture and Urbanism - PROGRAU-UFPel.

In other words, the Potential-Centrality Model measures the spatial relationship in urban systems internally, describing urban morphology at a given moment but indicating also the spatial system imbalance. Places with higher Centrality are places in convergence to urban changes occurrence. This convergence can be assumed as measure of urban growth Potential (Krafta, 1999).

The Potential-Centrality Model should not be taken just as a static morphological portrait. It can be assumed as an imbalance measure in urban system able to configure a set of urban growth vectors in near future. Growth potentials occur in greater economical opportunities, so in places with large centrality differences in surroundings (Polidori, 2004).

Originally Krafta's model operated from graph theory and could be adapted in a cellular automata (CA) urban modelling environment by Polidori (2004).

Graphs and cellular automata resources integrated in model set it up to explore urban morphologies by global and local relations. While CA works with spatial relations and neighbourhood relations, graph theory works the connections between different spatial units remotely. Thus, Potential-Centrality adaptation in a cellular environment (Polidori, 2004) allows advances on Krafta's original ideas (Krafta, 1994) once spatial relations are not limited through the graph path. Thus, Based on such these ideas, an Urban Growth Simulator development (Polidori, 2004) allows urban morphology replication in axial, polar, and diffusive forms.

In an iterative way, cellular centrality distribution configures spatial opportunities landscape overlaid on a resistances field of natural environment. There is an urban growth dynamic emergent from semi-deterministic and semi-stochastic logics. (Polidori, 2004).

As the city grows, it tends to interface with natural values and environmental resistances. These interfaces are overlaid places by urban growth potential and natural landscape attributes. This occurring urban growth potential on water resources attributes are natural-urban conflict places, setting a called urban edge effect on environment system. This edge effect can be associated with urban resilience idea, an index of urban-nature conflicts and a tipping point to morphological urban growth changes (Polidori, 2004).

Furthermore, as edge effects are shaped in linear forms, if natural landscape are approached by hydrography and streams, the edge effect is evidenced by overlapping urban potential and water resources resistances fronts in their linear forms.

In short, the edge effect on hydrography streams are convergent urban and natural places. This edge effect can be assumed as tipping point of a catastrophic cascades urban dynamic, as proposed by Batty (2009). Besides this(Further), such morphological urban growth interchange can be approached with complex system terms like phase transitions.

On urban modelling methods this work develops a simulation procedure operating sensitive to landscape hydrography. This procedure captures the urban growth potential on hydrography attributes. Thus, the related edge effect (Polidori, 2004) on water resources adjacencies.

$$wl = PotBuff / PotTot$$

$$wl = D$$

As read:

“waterland factor” is equal to the ratio between urban growth potential incident on hydrography buffers and urban growth potential's total.

“waterland factor” is applied as perceptual of diffuse urbanization forms, in each model interaction.

The procedure called "Waterland factor" (z is a ratio of urban growth potential on hydrography stream's buffers). According to Equation 1 the "Waterland factor" ("wl", in the model) corresponds to the percentage of Urban Growth Potential's total (in the model, PotTot)

incident on hydrographical spaces (in the model, PotBuff). In the Urban Growth Simulator this ratio is applied as an index to diffuse urbanizations in the urban growth dynamic.

Urban growth simulation integrated to hydrography: urban modelling in Pelotas city case [1815-1965].

In sequence, this work concerns on developed simulation growth procedure in validation and application terms. Studies are applied to urban growth of Pelotas case [1815-1965] empirically described in this paper's third title.

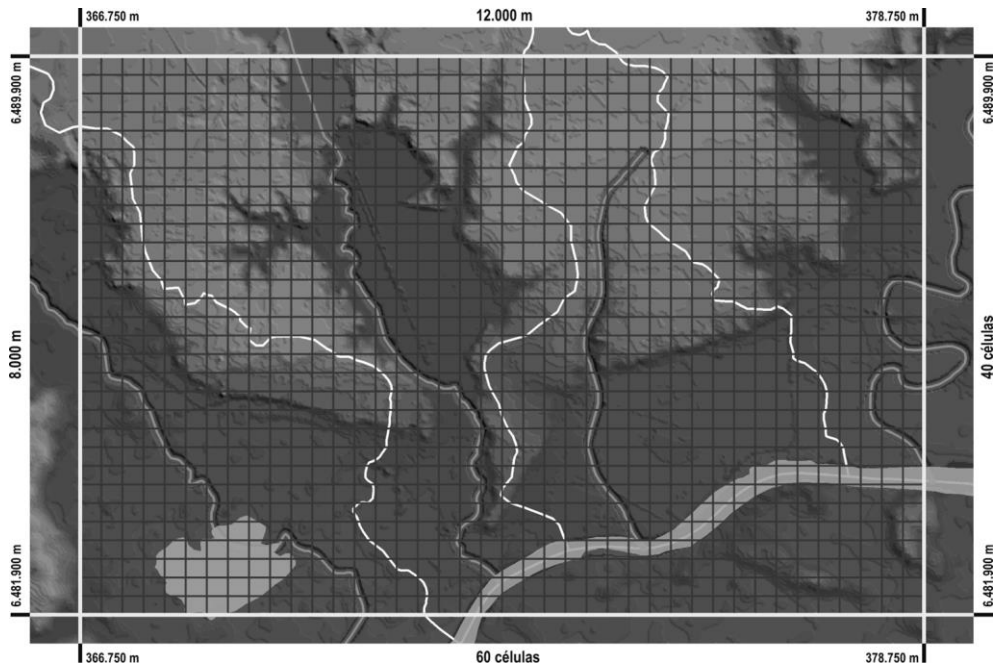

Figure 4 spatial delineation and simulation's disaggregated scale to Pelotas case, regular red grid represented on hydrographic landscape.

The spatial delineation and simulation's disaggregated scale are defined by a regular grid (red lines in Figure 4 below) with 40 rows by 60 columns, defining 2,400 square cells with 250m side. The surface is 96 km². A rectangle of 8 km side in north-south direction and 12 km side in east-west direction. The limits in UTM coordinates are on zone 22 south: a) northern: 6,489,900; b) southern: 6,481,900; c) western: 366,750; d) eastern: 378,750.

From vectorial data on a Geographical Information System (GIS) individual grid inputs were set up, as shown in Figure 5 and described in following:

- a) urban core (atrator, mutable; figure 5a): urban attribute loaded in two levels (weight 1,0 and 0,5, in red and light red);
- b) hydrography streams (resistance, mutable, weight 1; blue and light blue in figure 5b): resistance to urban conversion but removable on simulation process;
- c) external city space (resistance, freezing, weight 1; figure 5c): institutional attribute that prevents urbanization on external space to Pelotas municipality;
- d) hydrographic landscape (resistance, mutable, weight 1; figure 5d): environmental attribute, natural resistance matrix differentiated into five classes by interpolation between the drainage lines (higher resistance level 4, in green) and watersheds ridge lines (smaller resistance, level 0, in brown and white);

e) flooding areas (resistance, mutable, weight 1; figure 5e): environmental attribute, natural resistance matrix distinguishing flood tendencies by binary values (0 values in white or 1 values in pink).

f) random attribute (resistance, mutable, weight 1; figure 5f): resistance matrix differentiated randomly with values interpolated between 1 and 3.

Figure 5. regular grid inputs with 60x40 cells: a) urban core in two levels; b) hydrography streams; c) external city space; d) hydrographic landscape matrix; e) flooding areas; f) random attribute.

Below, the model outputs are shown on figure 6 and described below, which in sequence will be resumed to numerical correlations in simulations: CellType, representing the urban phenotype; CentABS, absolute cellular Centrality; CentR1, cellular Centrality normalized by mean values; CentR2, cellular Centrality normalized by max values.

From control scenarios a cell count (UrbanCount operation in model) of urban phenotype (CellType) could be calculated annual cell conversion rate, adjusting the simulations speeds. These values composes an urban growth rate of 1.88% percent annum, calculated for 130 years period. The simulations proceedings are set to occur in 50 iterations. Thus, the cellular conversion rate parameter is 4.95% by interaction.

After processed the urban growth simulating, in figure 7 are shown the outputs of CellType, Centrality, Growth Potential, Natural Resistance (CellType, CentR1, ResistE, respectively). Illustrated 8 of 50 total iterations (iterations 1, 8, 15, 22, 29, 36, 43 and 50).

Figure 6. model outputs of CellType, CentABS, CentR1 e CentR2; control scenarios to a) 1835; b) 1916; c)1926; d) 1965.

Numerical Correlations

Performed the simulation procedure that reply alternations in urban form on growth dynamic with visual evidences and similitude with Pelotas city in empirical reality between years 1815-1965. To forwarding, the urban modelling results need a numerical correlation with control scenarios to an effective validation of model mechanism developed.

To make results numerical correlations, the output iterations are associated with control scenarios through number of urban cells (UrbanCount). That is, from CellType number of each control scenarios (presented in Figure 6) is indicated an iteration with similar number of CellType, and thus proceeded a kind of dynamic correlation.

Accordingly, the correlation for the year 1835 is iteration 01; for scenario year 1916 the iteration 09; for scenario year 1926 the iteration 38; and year 1965 is correlated with iteration 50. The figures 8, 9, 10 and 11, shown below, represent the dynamics correlations from the Absolute Centrality (Figure 10), Centrality type 1 (Figure 11), Centrality type 2 (Figure 12) and urban phenotype, CellType (Figure 13).

In addition to visual correlations, the grid's numeric data can be compared with control scenarios by linear correlation (R^2) and plotted scatter diagrams (as shown in figure 12).

In the chart below, Centrality type 1 data points are plotted in a scatter diagram. Four distinct control scenarios are overlapping in crescent blue colour scale.

In scatter diagrams, the proximity between points and tendency line indicates best results. The best result achieved is Centrality type 1 with 0.79 of correlation, a significant statistic value.

The table 1 below shows numerical correlation results for outputs: Absolute Centrality (CentABS), Centrality type 1 (CentR1), Centrality type 2 (CentR2) and Urban Phenotype (CellType). Comparing numeric correlations between simulation procedure and control scenarios, a dynamic understanding is possible and better results could be compared.

Figure 7. simulation outputs with active waterland factor; shown 8 of 50 iterations:
a) Celltype; b) CentrR1; c) Potential; d) ResistE.

Figure 8. dynamic correlations between simulation and control scenarios to Absolute Centrality output.

Figure 9. dynamic correlations between simulation and control scenarios to Centrality type1 output.

Figure 10. dynamic correlations between simulation and control scenarios to Centrality type2 output.

Figure 11. dynamic correlations between simulation and control scenarios to CellType.

In Table 1, for each control stage are highlighted in deep blue the maximum values and in red the minimums. In the last column are indicated a scenario formed with mean values and the maximums values are highlighted in last line.

It is possible to observe that the majority of the maximum values happens in the Absolute Centrality type (CentABS, mean 0,85) and the minimum results are to urban phenotype (Celltype, mean 0,66).

The data showed in this chart was presented in linear graphs that allow to demonstrate the evolution of the numerical correlations for each of the outputs (centralities in variations of blue and urban phenotype in red). The graph of drawing 4.30 indicates better results for the results of centrality, that besides happening with larger values (means, 0,85; 0,79; 0,85), the comparative horizontality of the lines indicates a trend to occur constantly. This means that, during the process of simulation, (larger the horizon simulated, smaller the control of the data), the centrality correlations are almost the same.

Figure 12. scatter diagram from Centrality type 1 output data, overlaid scenarios 1835, 1916, 1926 e 1965, in crescent blue colour scale.

Table 1. Numeric correlation values for each output in four control stages

R ²	1835 x i_01	1916 x i_09	1926 x i_38	1965 x i_50	Média
CentABS	0,81	0,90	0,87	0,82	0,85
CentR1	0,79	0,81	0,76	0,81	0,79
CentR2	0,86	0,90	0,84	0,80	0,85
Celltype	0,90	0,53	0,52	0,48	0,66
máximo	0,90	0,90	0,87	0,82	0,85

Conclusions

Approaching urban growth and hydrographic landscape this paper approaches objects traditionally from different epistemological fields: city and natural environment. Furthermore, this paper main highlight is the approach from three different scientific bases: theoretical, empirical and methodological. From these three approaches the results are converging into a common result, reinforcing the statements proposed throughout the work.

Can be highlight too the explored relationships between urban growth morphologies and hydrographic landscape. From a widely perspective in a systems approach the watershed attributes influences urban dynamics in a complex relationship, overcoming cause-effect linear relations.

Thus, the work also overcoming landscape attribute approach operating as a simple urban resistance, merely constraining the urban form resultant. In fact, what is proposed is the urban form spatial discontinuity as an inherent growth dynamic characteristic. In this complex relationship hydrographic attributes are discrete, operating as a tipping point on urban-environment system.

The spatial convergence between urban voids and water resources are a way of ecological preservation on urban growth dynamic. Thus, the work sought to contributes to overcoming pessimistic views about urban futures. Traditionally urban futures have been summarized by the negative morphological impacts on natural resources. Rather, the results proposes the city as richest human artefact with intrinsic properties of vitality and expansion, associated with resilience and permanence factors over time.

In more specific terms, some discussions from this work can raised, as described below:

a) urban form fragmented and coincidence with natural landscape.

The results appointed the urban form fragmentation as an intrinsic characteristic to urban growth, emerging from multiple subsystems convergence.

The urban form fragmentation does not nullify the natural tendency of concentric urban growth. Contrariwise, this fragmented and concentric morphologic changes indicates cities

grow by both movements synchronously, featuring a dynamic that essentially defines as a complex phenomenon.

The occurrences of the fragmented urban form allows that the urban voids can match spatially to places of interest of the natural environment. Due to this, the dynamics of growth and the spatial discontinuity can be actually a path to better interact urban systems and natural ecosystems.

However, in order to occur in fact the city articulated to the natural landscape, before it is necessary to indicate a scale to foster the urban fragmentation and the urban voids effectively match to the important places of landscape ecology.

In this sense, some authors have anticipated and presented the integration between transport systems and the hydrological basins as a possibility to reduce costs of implementation of infrastructure and reduce the impacts of urban growth over the natural landscape. It is in such perspective and spatial scale that this work is integrated

b) spatial discontinuity intrinsic to the urban growth dynamic and the water resources role.

Urban theory has been applied to understand the spatial discontinuity of urban form.

In this context, statements from the New Economic Geography make possible to improve the understandings of the dynamics of growth and the spatial discontinuity from an evolutive approach of the urban theory path (Fujita e Mori, 1997). Due to the lag between South American and European history cities, this theoretical approach are applied successfully in Buenos Aires city by Janoschka (2002). Alike, as in this paper the NEG's "evolutionary approach to urban systems" is also valid for Pelotas' case, that urban growth is associated with concentric, sectoral and multi centrality evolutionary stages.

In terms of complex sciences this morphological changes has been referred as a phase transition dynamic, occurring as a catastrophic effects. Urban science would not just discover the attributes that characterize cities whereas complex system (Batty, 2009). In this sense, this paper take on the hydrographic attributes as tipping points in the complex system, where the environment converges to promote a dynamic.

c) urban growth morphology watershed's articulated.

On hydrographic urban sub-basins, the hydrologic properties configures wetlands in adjacent areas to drainage streams, defining constraints spaces to urbanization. This urban-resistant places are in contrasting with environmental amenities on terraces and watershed ridge lines.

In a watershed scale, original urban cores tend to occur due to proximity and distance with water resources. In general, looking for places in resemblance the idea of isotopic plans. Originated on environmental spaces like an isotropic formation, the urban core expands predominantly in concentric forms until confront with natural restrictions to urbanization. In the natural landscape, hydrographic streams are set as important attributes against urban built form.

In these places urban and natural interests are overlaid, configuring an interface where is restricted the concentric urban growth. To keep the urban spatial production is overcome the landscape restrictions and urban growth occurs in remote places. At this time, in general, diffuses urban nucleus tend to occur places resembling the original environment. Urban growth seek for environmental amenities on terraces and ridge lines beyond the hydrography's wetlands.

Repeating the original locational criteria, repeats urban growth expansion form and sets up an iterative and dynamic process, successively.

d) urban morphology, sustainability and performance.

This paper assumes the morphologic urban growth dynamic articulated with hydrographic landscape as a discrete property that gives cities a permanence factor over time, which in terms of urban ecology has been called in resilience.

However, that in fact occurs, the urban permanence also depends on the internal performance and difficulties imposes on social and environmental structures.

Certainly concentric city has the performance facilitated by enabling endless interactions occur internally, promoting accessibility to all spaces and socio-spatial relations with proper intensity and equity.

Though, the compact city model pursued by urban theory has not shown able to reducing the urban social costs and the human environmental footprint. Furthermore, concentric morphological models do not allow the natural landscape articulation, urbanizing indiscriminately environmental attributes and contributing to internal urban-environment problems.

On the other hand, urban fragmentation that a priori presents greater restrictions on urban efficiency, has been presented as an alternative to reduce the indiscriminate conversion of the attributes of the natural landscape, promoting preservation practices and ecological valuation on the city.

However, there are strong evidences that discontinuous urban form tends to maintain urban facilities in an unequal distribution and promote spatial segregation. In fact, like the tendency to promote diffuse urban growth, the spatial inequity is intrinsic to urban phenomenon and needs to be confronted by urban science.

That is, if in the contemporary city coexists: the socio-spatial segregation and urban the interaction; the urban artificiality and environmental nature; the morphological fragmentation and concentration. Urban science must develop a model that involves both efficiency, equity and environmental quality, simultaneously. Construct a new science paradigm that ensures the urban sustainability and permanence over the times, in fact.

Epistemology of public spaces: a cultural approach

Malgorzata Hanzl

Institute of Architecture and Town Planning, Lodz University of Technology

Al. Politechniki 6A, 90-240 Łódź, Poland. E-mail: mhanzl@p.lodz.pl

Abstract. *Cultural aspects of urban settings require developing methods of description of public spaces. The current paper addresses the problem of a theoretical exploration of the analysis of public space from a dual perspective: morphological and anthropological. It claims that the void constituting a physical manifestation of the public realm is a common element which is in the scope of interest of both disciplines. For public life to occur in urban areas necessary conditions are required. Anthropologists endow forms of urban spaces with meaning, treating them as a form of communication. Inversely, claim may be made that a lack of formal definition of urban situations results in a decrease of meaningful communication itself, thus, as a consequence, public life withers in outdoor spaces. The quest for methodology for description of public spaces, including their physical form, becomes crucial in this perspective. The description of culture based differences of appearance of various outdoor spaces requires detailed analyses of cues pertaining to the notion of atmosphere perceived in distinguishable settings. The current paper conveys some entry points to a more systematic exploration of public spaces.*

Key Words: *Urban design, public spaces, urban morphology, enclosure.*

Introduction

The Postmodernist shift of approach towards research in the field of urban design requires the development of an exploratory framework for the epistemology of the public realm. The current paper aims at a trial to review the main threads related to the epistemology of urban open spaces. While studies in urban morphology have flourished recently, after the period of Modernist stagnation the paucity of theory on morphology of urban open spaces is still perceivable. Morphologists recognise that "(...) *the city or town can be 'read' and analysed via the medium of its physical form*" at the same time pointing at the tight and dynamic interrelationship of urban structures shaping and being shaped by social and economic forces (Vernez Moudon 1997, p.7).

In order to establish the epistemological position at the outset, it is necessary to recognise the lack of theory which may convey the explanation of relations between the way people use open urban spaces and their physical form. Gauthier and Gilliland (2006, p.44 after Levy, 1999, p. 79) suggest that comprehension of the urban fabric in terms of 'urban form' should assume treating elements of urban structure as linked together and creating a whole, governed by an 'internal' logic. This postulate recalls the structuralist position within anthropological research, namely the concept of 'the order of orders' discussed by Lévi-Strauss (p.332).

The requirement to include culture related aspects of urban structures into the normative theory of urban design should be recognised. The author tries to fill in this gap, in the quest for common threads enabling the commensurability of the theoretical framework of anthropological studies and the epistemological approach of urban design and urban morphology. This paper identifies some threads in urban design writing which refer directly to the description of urban settings that may be characterised as culture related. It looks for their overlap with anthropological theory, namely the structuralist approach presented by Levi-Strauss as well as ideas developed by the archaeology of space.

The paper is organised as follows: after this introduction, the explanation of structuralist theory is presented with regard to urban settings. Further on, a review of urban design writing is

performed. The last section discusses the perceived overlap of the two theories and potential future research avenues. It also summarises conclusions from the paper.

Links between anthropology and studies of urban morphology

Levi-Strauss attributes different aspects of social life to the unconscious activity of the mind, which consists in imposing forms upon content (p.30). He discusses "(...) *interpreting society as a whole in terms of a theory of communication*" (p.89). This endeavour may be undertaken on three levels: the rules of kinship and marriage, economic rules and linguistic rules. (p.89). In his opinion, it is legitimate to search for homologies between these levels, as well as to look for reflections of social structure in the spatial organisation of human settlements - again on various levels (pp.290-291). He distinguishes direct and indirect communication and points at rules of communication games which constitute an important element of culture (pp.296). Social institutions find their projection in the space around them, which refers not only to primitive societies but also as Levi-Strauss ephasizes: "*most modern cities present spatial structures which can be reduced to a few types and which provide certain indexes of the underlying social structure.*" (p.329). He discusses "*the order of orders*", which "*is the most abstract expression of the interrelationships between the levels to which structural analysis can be applied.*" (p.332). The question raises which physical features of urban spaces evoke what kind of notions and how these phenomena function.

The anthropological concept of walking, elaborated by Certeau (1988, p.98) as a space of enunciation and his comparison of the usage of space and urban structures to speaking in a given language, provides a valuable asset for analysis of the way urban spaces are created through embodied practices and read. A desirable harmony of urbanscapes requires congruency of the form of structures and of human behaviour. Certeau (1988, ix) discusses a concept of singularity – in this approach defined as the scientific study of relationship - that links everyday pursuits to particular circumstances.

Morphological approach

The principles of morphological analyses assume analyses of the form of physical elements at different levels of resolution and taking into account their changes in time (Vernez Moudon, 1997, p.7). The resolution of analysed structures corresponds respectively to the levels of a building/lot, street/ urban block, city/ region. They are the subject of analyses of the three different main schools of urban morphology: (1) Conzenian, following the thought of M.R.G. Conzen (Whitehand, 2001) - mainly British and German, although developed as well in the neighbouring countries, (2) Italian, continuing the tradition of Muratori (Cataldi et al, 2002) and (3) French, started by Panerai and others (Panerai et al, 2009).

The classification of research in urban morphology (Gauthier, Gilliland, 2006) places the oeuvre of morphologists, who incline towards an anthropological method (Rapoport, 1969, 1990, 2003; Rykwert, 1989; Mumford, 1989; Lynch, 1994), on the border between the cognitive and normative approach, which provides characteristics both of existing places and looks for normative theory in the field of urban design. Detailed analyses of open urban spaces were conducted as an element of plot profile analyses by the French school of urban morphology, such as studies of tenements in Versaille by Castex and Celeste (Panerai et al, 1974).

The recognition and characteristics of elements of urban structures as defined by Lynch (1960), namely: nodes, paths, regions, edges and landmarks, introduces analyses of outdoor spaces from the cognitive point of view, in a more holistic approach. Lynch and Rodwin (1991, p.361) distinguished two basic classes of urban structures: the built up plots and open outdoor spaces. When looking for the description of 'a system of activity pattern' they point at the requirement to concentrate on two basic aspects: flows of men and goods and spatial patterns of

'localized activities', including: exchange, recreation, sleeping and production. When concentrating on physical patterns, this breakdown may be transpositioned to the description of the physical form: "(a) the flow system, excluding the flow itself; and (b) the distribution of adapted space, primarily sheltered space." (Lynch and Rodwin 1991, p.361). In the first group there are roads, paths, pipes, wires, canals and rail lines - that is all the elements which "are designed to facilitate the flow of people, goods, waste, or information". The second type consists of all spaces that "have been adapted in some way to be useful for someone or several significant non-circulatory activities." (Lynch and Rodwin 1991, p.361-362). In this group, apart from urban structures, understood as volumes, there are also the open spaces of squares, markets, streets, parks, etc.

Definition of enclosure

The notion of enclosure should be evoked here as it constitutes a physical representation of open, publicly accessible, outdoor space. It has been present in the language of description of landscapes since 1235, that is since the Statute of Merton (Holmes 1910, p.479). It further developed on the ground of landscape architecture. In the classic handbook by Hubbard and Kimball (1917, after Böhm 2004, p.12) *inclosure* or *enclosure* is defined as a result of plan composition, which provides, thanks to the introduction of proper divisions, an impression of interior regardless of the location of an observer. Ashihara (1983, p.34) underlines the importance of walls in western culture. Ramparts of medieval castles created a "centripetal order ruled by the wall".

Outdoor spaces are physically delimited by a boundary consisting of facades of buildings, fences, greenery, etc. The void defined in this way is an element commonly perceived as a physical manifestation of a public realm, thus, may be considered as providing an opportunity to apply a theoretical framework stemming from anthropological studies and urban morphology. Cullen (2008, p.29) describes enclosure as "the most powerful, the most obvious, of all the devices to instill this sense of position, of identity with the surroundings." He emphasizes the role of enclosure in defining the idea of *Hereness*. In this context the concept of place which is distinguished from space by means of meaning and recognition (Tuan, p.73) acquires more physical shape. The singularity of definition is one of the features enhancing the 'imageability' of an urban environment which is strongly emphasised by Lynch (1960) for whom the sharpness of a boundary or presence of an enclosure is one of the possible ways how singularity may be achieved.

Ashihara (1981) discusses concepts of positive and negative space, in which tensions are directed respectively inward on the centre or outward from the centre. He claims that, from the viewpoint of space theory, planning is an activity which consists of the determination of boundaries and then building of an order inward, towards the centre. Many postmodernist theoreticians point out the same distinction. Krier (2011, p.169-170) rejects public spaces created without a conscious concept of definition of boundaries (N-type) as accidental and chaotic.

Streets as well as squares, piazzas, etc., conversely to 'empty ground in the Gestalt scheme' of wide spaces between buildings in mass-scale modernist planning, may demonstrate the qualities of Gestalt figures, in this case the boundary, which separates the interior and exterior space, becomes the 'inside wall' of the enclosure (Ashihara 1981, pp.141-142). Observation by Norberg-Schulz confirms that in order to become a true form, the street must possess a 'figural character' (Norberg-Schulz, 1963, p.83, after Ashihara 1981, p.142).

Space is experienced in a dynamic way, urban spaces are examined from an endless number of viewpoints along with movement of an observer through sets of consecutive enclosures. The return of sequential analyses of urban spaces, which address perception from a pedestrian perspective, including changes in observer position - that is perception in time - started with Sitte (1996). In parallel, the continuation of the British Picturesque tradition was developed by

Cullen (2008), who referred to more subtle notions, that is, visual perception, but also to other parameters of settings, including multi-sensual perception: tactile, acoustics, smells, etc. Further more contemporary development of the theory in the Anglo-Saxon tradition has been carried out by, e.g., Venturi et al. (2001) with regard to urban strips.

Nowadays concentration on the human perception of cityscape has become quite a common approach within a field of urban design. This group of analyses also contains psycho-geographical examinations of a cityscape, (e.g.: Debord, 1955, Nold, 2009). The current shift from the 2d approach to planning of urban areas, towards emphasis of perception from the pedestrian's perspective is another reason for the increased attention paid to the appearance of 'spaces between buildings' (Gehl, 1987).

Culture related character of public spaces

Ashihara (1981, 1983) pays attention to the differences between the appearances of public spaces in various cultural contexts. In his work (1983) he concentrates on the way outdoor space is approached in Japanese culture and European tradition, namely Italian. The obvious distinction between Japanese culture, with its characteristic visual incorporation of external spaces into interiors, and Western spatial order (Ashihara 1983, p.34) indicates the presence of various "*spatial orders*". More detailed analyses allow us to notice the much less obvious distinctions, which express themselves in variations of rhythms of facades, heights of buildings, their distribution and distance from streets, ways how streets profiles and silhouettes are shaped, etc. These observations are congruent with Rapoport (1990, p.89) who claims that "*the ordering principles of fixed-feature arrangements have meaning, although one group's order may be another's disorder*". Lynch and Rodwin (1991, p.355) point at the custom as one of the reasons for "*choice of form*" in the design process.

Rapoport (1990, p.49) argues that one of the channels of visual communication is the built environment and emphasises its meaning (1990, p.91). He points at the presence of '*visible and stable cultural categories*' made by physical elements and moreover he states that there is the possibility to decode the meaning of urban settings under the condition that '*they match people's schemata*.' (Rapoport 1990, p.15).

Anthropological perspective

The anthropological approaches confirm the observation expressed above. According to Hall (1989): "*structures provide context, which enables communication*". People must have the ability to interpret codes embodied in the built environment which is possible when they represent the same culture. The factor which intercedes between the cognitive absorption of perceived visual stimuli and the creation of new environment is visual awareness. Hall (1966) distinguished three main types of elements which undergo changes as a result of a culture specific communication processes: (1) fixed-feature, (2) semifixed-feature, (3) nonfixed-feature ones. The way fixed-feature elements are organised, their spatiality, size, location and arrangement transform meaning, especially in traditional cultures. The territorial distribution and exchange of nonverbal cues serves the communication purpose and usually certain semantics may be attributed to it (Goffman, 1959). Anthropologists developed elaborated theory on ways in which a site is converted into a meaningful 'place', by inscribing human activities into the surroundings.

Important indications on how physical settings may be 'read' and understood may come from the field of archaeology, where anthropological theory and practice are being abundantly developed (Hodder, Hutson, 2010). Special attention is given to the notion of meaning of material culture objects: "*the idea of meaning is making sense of the situation*" (p.157).

Following Hodder, all objects of material culture, including physical settings, are entangled in some activities and it is impossible to consider them separately (Hodder, 2012).

The overlap of theories coming from the two disciplines

The concept of situation, which is essential for current considerations, was defined in the 1920s as a “*constellation of the factors determining the behaviour*” (Thomas, 1937, p.8 after Schumacher, 2011, p.420). Goffman (1959, p.18) explains the notion of situation as “*the full spatial environment anywhere within which an entering person becomes a member of the gathering that is (or does then become) present*”. The term is understood in anthropology as a theatre of human activities (Perinbanayagam, 1974). In the morphological approach, the above concept is reflected by the notion of habitus (Panerai et al, 2009) characterised by a set of identifiable cues, which may be qualified as culture-specific. They refer to physical space, including features like: “*quality, size, shape, enclosing elements, paving, barriers, and links, etc.*” (Rapoport, 1990, p.106). Rapoport emphasises the role of physical settings “*(...) it is the social situation that influences people’s behaviour, but it is the physical environment that provides the cues.*” (Rapoport 1990, p.57)

The relationship between people and sites encompasses both: attaching meaning to space and “*recognition and cultural elaboration of perceived properties of environments in mutually constituting ways through narrative and praxis*” (Lawrence, Low, 2009, p.14). Hillier and Hansen (1984, p.224) ponder on the method of investigation of encounters as morphic languages, concluding that the aim is to establish how encounter systems acquire differential properties which would have different manifestations in space. Hillier emphasises the role of human cognition in the creation of cities, at the same time also pointing at the culture based differences in their structure (Hillier, 2009). His research, in cooperation with ethnographer Jean Cuisenier (Depaule 1995, p.30), encompasses the relation between urban composition and 'social logic of space'.

The social cues discussed hereto may be twofold. First they are related with some prescribed rituals, unique for a given community and thus belong to conscious activities. Second, the nonverbal communication cues associated with the group behaviours and proxemics issues, including interpersonal distances and distribution of people in communication situations, affect the form of physical settings as well (Hall, 2009). The claim is made that the rules which govern the non-verbal communication component of the human group behaviour, its intrinsic organisation and arrangement, constitute the internal order which lies behind distribution of cues in urban settings. They both represent the same culture of space usage.

Methodology of the description of physical spaces - state of the art

In order to make the case for a more systematic appreciation of the physical attributes of open public space, arguing that such attributes trigger cognitive and behavioral responses associated with deeply seated cultural meaning, a review of current practices is further provided. The basic method of gathering data for projects both in urban planning and urban design is the inventory and analyses of urban landscapes. Direct contact with the environment enables observation and validation. Rapoport (1990, p.97) suggests direct observation, analyses of existing studies, and an analysis of descriptions and the like as a method of verification of the thesis on nonverbal communication role of the environment. He provides a comprehensive list of potential cues, which should serve as a basis for description (1990, pp.106-107), which includes elements of vision, sounds, smells but also social aspects, such as characteristics of people, activities and uses and objects present in outdoor spaces.

The theoretical body for this kind of studies is derived from Lynch's theory (1960). Further classification of the two basic categories: adapted spaces and flow systems, should pertain to the

following features: (1) element types, (2) quantity, (3) density, (4) grain, (5) focal organization and (6) generalised spatial distribution (Lynch and Rodwin 1991, p. 362-363). The typologies of public spaces were the subject of investigations by many authors, e.g., Krier (1975) undertook a trial to formulate a typology of squares, based on their shape and Jacobs (1995) provided an elaborated typology of streets. Discussing these typologies in relation to the culture of usage of space, it is necessary to take into account cognitive aspects of form, which precede the creation of physical objects and notions which are related to these concepts (Caniggia and Maffei, 2001, p.50).

Another characteristics of urban enclosures is connected with their proportions, which also influence both perception and understanding of settings. Ashihara (1981, p.41) analysed changes of proportions of street profiles in various periods. He bases his approach on the relation of building height (H) to street width (D) and further also to the width of the facade (W) (Ashihara 1983 p.141). The D/H factor emphasises Gestalt qualities of exterior urban landscape composition. The qualities of contextual design advocated by disciples of Sitte's oeuvre reendow it with proper significance.

The analogous theory of urban composition was developed in Polish architectural writings by Wejchert (1984). He discussed a similar set of elements of urban structure to Lynch, though based on the epistemological ground of urban composition. He is widely recognised for the comprehensive theory of urban enclosures. He introduced the notion of central angle, defined as an angle between a horizontal plane parallel to the floor at the height of 1,5m (the medium level of sight for humans) and a line going through the highest point of the building defining the closure in a given profile. The point belongs both to the silhouette line and to the cross-section. Wejchert (1984) provides general rules for classification of enclosures basing them on the description of heritage sites which are widely recognised for their great proportions. According to his classification, enclosures may be divided into complex and simple, elongated and neutral - close to square. He discussed also openings - breaks in a line of facades, which he classifies into narrow, neutral and large, and following their content: architectural or natural. Among other concepts defining a composition of urban landscapes, there are notions of leading and retaining (stopping) lines and planes, rhythms, visual axes, vantage points, landscape openings, etc. (Wejchert, 1984, Żurawski, 1962).

In order to define the understanding of a city as consisting of multifarious "*sensuous experiential orders*", a concept of an atmosphere has been introduced by Böhme (2004, after Andersen, 2012) defined as "*a spatial character we experience through our bodily presence*". In the architectural praxis a "*phenomenological survey*" of cityscape is conducted, which allows distillation of "*sensuous quality of space*", which finds further application as input standards for transformations. Following definition by Andersen (2012), atmosphere belongs to the interstice between an articulating physical object and a sensing human body. Böhme claims atmosphere to be evoked by "*orientation, suggestions of movement (and) markings*" creating "*concentrations, directions, configurations in space*." (2002/2005, after Andersen 2012). He points at four main factors pertaining to the way an object is sensed by a human body and what emotional response it elicits: form, colours, proportions and texture.

People develop a better understanding of the world through experience, starting from early childhood, the abilities to assess 'gravity, hardness, surface character, thermal conductivity' together with the geometry of shapes (Rasmussen, 1964) is acquired. This deftness is a result of experience collected by a youngster along with the culture of usage of space. A phenomenological survey should point out a number of properties of a buildings' facades pertaining to an overall spatial character: (1) contour, (2) shift (like shift of cornice providing dynamic transition between neighbouring facades), (3) colours palette, (4) profile - (e.g. of the cornice), (5) relief, (6) plasticity - twists of line of construction, corrugation, (7) rhythm - of facades, windows, lamp posts, etc, (8) framing as emphasis of architectural elements, (9) pattern - touchable, increasing tactile qualities (Andersen, 2012). The above listed distinctive building elements pertain to form, colour, proportions and texture qualities of an open space.

Conclusions and further research

The challenge, stated by Hall (1989, p.55), is that, in a globalising world, humans should discover ways how “*basic cultural systems such as time and space are used to organise behaviour*” have become popular in contemporary urban design thought, as numerous studies show (Schumacher, 2011). At the same time, the studies of urban morphology are going through a period of intensive revival after a break associated with the activities of modernists and attract the attention of numerous researchers all over the world, as Gauthier and Gilliland (2006) point to in their survey.

Outdoor open urban spaces provide settings for the social life of a community. They convey the framework for social situations endowed with cultural meaning. The characteristics of enclosure, including its scale, profile, definition, the character of walls and floor as well as characteristics of space: odours, temperature, etc, make up the perceived image of these places. The requirement to grasp the physical attributes of outdoor space in a more systematic way has been recognised, in respect that such attributes elicit cognition embedded with cultural meaning. The heretofore research on the character or atmosphere of urban outdoor spaces were mostly descriptive ones and were carried out on the basis of historical studies. An extensive set of such culture dependent features as well as some theoretical assumptions were introduced by Rapoport (1990) and Rykwert (1989). Valuable observations referring to the quality of public spaces come from urban design theory, namely the works of Lynch (1960), Lynch and Rodwin (1991), Wejchert (1984), Ashihara (1981, 1983). In all this research the importance of the definition of space in the form of enclosure is emphasised. The ability of a boundary to be read as a profile or set of profiles based on the Gestalt theory is underlined as the one which especially influences human perception. Some normative approaches towards the examination of urban structures (e.g.: Andersen 2012) include phenomenological: tactile and sensual experience, essential for perception of architecture. The creation of atmosphere which refers to the character of urban outdoor spaces remains central in the design process.

The urban settings are the subject of elaborated research in the field of anthropology. As Hall states (1966 p.88) “*(...) settlement pattern both relates to the core values of the culture and contrasts with the other patterns around it.*” The meaning of space is explained by contextualisation provided by the built environment which should help citizens deal with the overload of information related to certain cultural settings. The social cues may be twofold: the first related with some conscious activities and the second, unconscious, reflecting the group behaviour related with proxemics. This ‘*spatial order*’ may be interpreted as a set of rules lying behind the way urban spaces are unfolded in urban settings of various cultural backgrounds.

The necessity for more systematic research on the relations of the two spheres - human activity and physical settings framework has been recognised. Further research is envisaged, including different approaches to the analyses of urban silhouettes and profiles, the sequences of views over time and the character of the buildings themselves as well as the verification of analyses of various types of visual cues through the analyses of a case study.

The interaction between urban form and public art. Two examples on Lisbon's waterfront

Rita Ochoa

CIES.UBI/Cr Polis.UB. E-mail: rita.ochoa@ubi.pt

Abstract: *In our contemporary cities, public art plays an important role, in urban regeneration processes and in the construction of social identities. Its placement on the public space raises several questions: which spaces are elected for the implementation of public art? In those spaces, what kind of relations are established between its morphologic characteristics and the new interventions? Finally, is it possible to identify models of placement? Despite the lack of systematization of these themes, some authors focuses on the interaction between urban space and public art, in a framework that positions it across different disciplines. In Lisbon, the criteria for the placement of public art are not always evident. Most of the times, there is not a true spatial integration. In this sense, this paper proposes an analysis of two artistic interventions, on Lisbon's waterfront: The intervention in a viaduct, by Eduardo Nery (2003); The work Lisbon (a tribute to the builders of the city), by José de Guimarães (1999). By the way as they dialogue with its context, both interventions are in the opposite attitude of an understanding of public art as decorative objects on the public space. In fact, both contribute not only to the physical, visual and symbolic enhancement of the place, but also to the monumentalization of the waterfront.*

Key Words: *public space, public art, urban form, Lisbon, waterfront*

Introduction

Throughout the second half of the 18th century, public art has enhanced the city's public spaces. In such a context, the production of monuments or smaller works like busts or statues has been interwoven with the urban design processes. Progressively, across the 20th century, the public art monumentalization paradigm has changed, but still the values of monumentality remained, assuming new ways of expression. Recently, urban regeneration actions have included public art programs as a way of providing new public spaces of symbolic contents.

The placement of public art in the city raises several questions: which spaces are elected for its implementation? In those spaces, what kind of relations are established between its morphologic characteristics and the new interventions? Is it possible to identify models of placement? Finally, is it possible to relate different historical moments with certain paradigms of monumentalization?

Despite the lack of systematization of these themes, authors such as C. Sitte (1889), Stübgen (1906), Jaussely (1907), Hegemann & Peets (1922) and more recently Kostof (1991), focuses on the interaction between urban form and the placement of monuments, in a framework that positions public art across different disciplines.

In our contemporary cities, some spaces seem to have a greater readiness to host public art interventions. Thus, it appears frequently in historic centres, in areas of urban sprawl, in gardens and parks, in new residential districts, among others.

In port cities, the inherently symbolic nature of waterfronts makes them privileged spaces for the placement of public art, and Lisbon is no exception (Remesar, 2002; Ochoa, 2012). Its waterfront is a large repository of built heritage. This display of Lisbon and that of Portuguese legacy contains historical and emotional value that reinforced the strong symbolic character enclosed in the city's waterfront. As a result, not only the city's identity is bounded in this area but the nation's character as well.

Retrospectively, and directing now a perspective upon chronological events, Lisbon has hosted two significant events that both enclosed ambitions of affirming national identity in two very different political contexts (Matos, 2013).

The first was the Exhibition of the Portuguese World, held in Belem in 1940, that celebrated the Nation with two centennial events: the eight hundred years of the Foundation of the Portuguese State (1140) and the four hundred years since the Restoration of the Independence (1640). The once densely industrialised area transformed into a cultural and leisure area, which promoted great symbolic expression through several emblematic buildings and monuments related to the Portuguese discoveries.

Almost six decades later in 1998, the Lisbon World Exposition (Expo'98) took place on the eastern side of Lisbon that celebrated the wonder of the discoveries with the theme 'the Oceans, a Heritage for the Future'. Expo'98 also aimed at rehabilitating a long extension of obsolete and disjointed areas in Lisbon leading to the creation of a new centrality.

The public space network that is enclosed within Lisbon's waterfront offers a wide range of opportunities for public life, socialisation and communality. As an example, recent investments took place that resulted in urban renewal and rehabilitation projects¹⁶⁵ within various particular areas of the waterfront. In particular, one can address the examples of: (i) the construction of the new 'Museu dos Coches' near Belém¹⁶⁶; (ii) the new public space of 'Ribeira das Naus'¹⁶⁷ next to Praça do Comércio; and, (ii) although still in its initial phases, the cruise terminal at Campo das Cebolas¹⁶⁸, offering a greater and wider variety of public spaces.

As previously discussed, Lisbon's waterfront is a privileged space for the placement of public art and, in particular, monuments of strong symbolic nature. In turn, the placement of public art is also a way to value the inherently symbolic nature of the waterfronts and to emphasise its monumentality¹⁶⁹. A predominant example of this is the strategic placement of the Equestrian Statue of D. José I¹⁷⁰ in Praça do Comércio (as part of the 'Baixa Reconstruction Plan'¹⁷¹), in clear owe and representation of the King's power. This monument is currently a symbol of the city, due firstly to its referential value, and secondly because of its relation with the surrounding urban space. Furthermore, other relationships are of particular interest such as that with the square, and with the Tagus River. Lastly, its surrounding permeability is of significant value owing to its monumental axis of articulation with the riverfront, and from Rossio (also reconstructed by the same plan) to Cais das Colunas (at the same time, a physical and symbolic entrance door to the city).

The monumentalization of Lisbon's waterfront. Two examples of public art integration

Along Lisbon's waterfront, one can find a wide variety of works of public art, regarding its physical characteristics (scale, size, shape, materials, colours, and so on) and also the type of

¹⁶⁵ Initially lead by 'Sociedade Frente Tejo S.A.' and succeeded by the municipality of Lisbon.

¹⁶⁶ Architecture: Paulo Mendes da Rocha + mmbb + Bak Gordon Arquitectos; project date: 2008-2009.

¹⁶⁷ Project Consortium: João Gomes da Silva GLOBAL, João Ferreira Nunes and Carlos Ribas PROAP; project date: 2009.

¹⁶⁸ Architecture: Carrilho da Graça Arquitectos; project date: 2010.

¹⁶⁹ However, it is important to remember that the monumentalisation of the waterfront is, in many cities, conflicting. As S. Kostof states, 'the issue of monumentalizing the water's edges is complicated by functional arguments. To the extent that a river is a working watercourse with a port, there is a definite conflict between those who make use of it for trade-related activities and those who would turn into a work of art' (Kostof, 2005: 41).

¹⁷⁰ This statue was executed in 1775 by Joaquim Machado de Castro, according to previous drafts by Eugénio dos Santos.

¹⁷¹ After the Earthquake of 1755, the Reconstruction Plan of Baixa is directed by Eugénio dos Santos and guided by Sebastião José de Carvalho e Melo (Marquês de Pombal). The new Praça do Comércio redesigned the previous Terreiro do Paço, through a U-shaped square, open to Tagus River.

relationship established with the respective public spaces (Ochoa, 2012). However, the criteria for the placement of public art are not always evident. In some cases, there are thematic correspondences between the works and the respective places, but most of the times there is not a true spatial integration. Finding this sense of integration, it is here proposed an analysis of two interventions on Lisbon's waterfront:

1. The "Intervention in a viaduct", by Eduardo Nery (2003);
2. The work "Lisbon (a tribute to the builders of the city)", by José de Guimarães (1999).

Both artistic interventions are positioned at the intersection between the waterfront and the urban axes which give access to it (Fig. 1). However, as the physical characteristics of the works are also quite different, the relationship with the place is also expressed in very distinct ways.

Figure 1. The placement of the two analysed works, at the intersection between the waterfront and the urban axes which give access to it. (From top to bottom): a) "Intervention in a viaduct"; b) "Lisbon (a tribute to the builders of the city)".

The Nery's intervention starts on Avenida Infante Santo and integrates two types of situations (Fig. 2): i) the application of a composition of tiles in some of the walls that define the access to the waterfront, between Avenida Infante Santo and Avenida da Cintura do Porto; ii) the painting of the viaduct and its walkways, on Avenida 24 de Julho.

Figure 2. "Intervention in a viaduct", by Eduardo Nery (2003)

Although it is also visible from the walkways, this work is more related with the roadway. It is important to note the continuity of this work with a sequence of other interventions, from several artists, on the beginning of Avenida Infante Santo. By the way that it stands along this path, all this set of public art interventions has the effect of underlining this axe of connection with the water.

In this underlined structure, the public art emphasizes the waterfront along the axis of access to it. One detail of this work is the application of colour on the viaduct. Thus, rather than accentuate the view of the water, public art also underlines/highlights the way to get to it.

By this way, public art has her a direct relationship with the place of which it belongs. In this case, it is not about existing or not an interaction with the urban space; or of the work being thought to be located on that place. This work could never be replaced, simply because it is in direct relation to the walls of the Avenida Infante Santo and with the viaduct. We cannot

imagine it any other place. Thus, this is undoubtedly a case of public art's integration with its surroundings.

Its abstract character does not have any theme or memory recall. However, without this intervention, the viaduct would certainly have a different expression on urban space. Thus, this intervention has as effect a enhancement of that place, defining a first paradigm of interaction between public art and urban space: the highlighting of a place through public art.

The José de Guimarães intervention is located at the Praça 25 de Abril (next to Doca do Poço do Bispo) and consists on a set that integrates (Fig. 3): i) a sculpture with strong colors (red, green and white); ii) a pedestal with seven steps; iii) a pavement design.

The sculpture is aligned with the access axis to the waterfront and centred on the square. The physical characteristics of the work (the scale, the strong colours and the fact that it is very elevated in the square, through the 7 steps) and the physical characteristics of the axis (based on a straight line and descending towards the waterfront) provide a visualisation of the water, along the route. As in Eduardo Nery's intervention, public art has also a constant view along that route, although differently: here configuring a fixed point, at the end of it.

The descending towards the water has also as a consequence that, in the beginning of the axe, the sculpture and the water are at the level of the eyes. As we descend, the sculpture, that represents a seated woman, goes up, relatively to the horizon line, until in a certain point where she is "seated" on the water.

The pavement design is only visible in its nearby, after arriving to Praça 25 de Abril. Only from a higher level – after climbing the 7 steps – it is possible to perceive the drawings in the floor.

Figure 3. “Lisbon (a tribute to the builders of the city)”, by José de Guimarães (1999).

The place of this intervention as the designation of “square”. However, as it is possible to confirm in the territory, this space doesn't function as a real square, because it has no permanence on it; in practice, it works like a roundabout. We know the existence of the project Jardins de Braço de Prata, contemporary to this artistic intervention and that supposed

collaboration between the Sculptor José de Guimarães and the Architect Renzo Piano. Perhaps, that project would include another kind of space experience, or even another kind of work placement.

In terms of placement in urban space, this work has similarities with the previously mentioned Equestrian Statue of D. José I. Both works are placed on a pedestal, in a square near the water, and both are not exactly centred on the respective squares, they are rather closer to the water, probably with the intention of favouring his framing. However, if D. José I has an “advocativo” sense (Remesar, 2011), in a clear owe and representation of the King’s power, the work Lisbon is a tribute to the builders of the city, but also to the city itself.

With a strong symbolic content, the tribute to the builders of the city also chose an emblematic place in the city. Being Lisbon a riverside town, the choice of the waterfront, next to one of the entrances to contemporary event “Expo'98”, seems very intentional. Thus, we have a celebration of Lisbon and of its builders through the placement of this the work, in that site. On the other hand, the site is also celebrated, through the work.

i) The creation and the design of a new public space (a square in the waterfront); ii) the decision on the placement of the work; iii) and finally, the work itself; all these aspects define a second paradigm of interaction between public art and urban space: the celebration of something that establishes a symbolic relationship with a place, through public art.

Conclusions

Waterfronts are privileged spaces for the placement of public art. However, in Lisbon, the criteria for its placement are not always evident. Most of the works do not profound the relationship with the place. Few situations promote a true morphologic and visual symbiosis between the public art and its context, limiting it to some thematic associations.

Also the time lag between the making of the works and their placement in the public space, or the removals and dislocations of some works (Ochoa, 2012), sometimes to completely different contexts, confirm that the relationship with the place is not always considered.

In the opposite attitude of an understanding of public art as decorative objects, the two analyzed examples represent an interaction with the place, according to two distinct paradigms:

The highlighting of a place through public art (“Intervention in a viaduct”);

The celebration of something (a fact, an event, an important person) that have a symbolic relationship with a place, through public art (“Lisbon (a tribute to the builders of the city)”).

These two ways of public art integration relate not only to the waterfront (horizontal logic), but also with the axes of articulation with the city (vertical logic). Both contribute not only to the physical, visual and symbolic enhancement of the place, but also to the monumentalization of the waterfront.

We finally conclude that, although the placement depending on the thematic – trough the toponymy, or trough the association of certain persons or facts to a place – already represents a way of symbiosis between public art and its environment, its implementation in the urban space should seek for a deeper integration; promoting, whenever possible, relations with the urban morphology, but also with the social reality to intervene. Public art should be it in relation to its environment, not as an isolated object. Its integration in the urban space and the dialogue with its physical and social context are essential for the construction of meanings in the city.

Abstract. *Developing wind energy in built environment is an old topic for sustainable city dwellers. With improvement of computer science, CFD simulation with complex building configuration or city models becomes accessible. This paper tries to analyse urban wind energy potential by urban form research. Two groups of idealized models were experimented for analysis of the impact of building size configuration and courtyard configuration in a semi-urban environment. Results show that the impact of building length on wind potential over the roof is much important than the building width. In addition, three typical urban form types in community scale were chosen and a set of morphological indicators were defined. The cross-comparison on wind energy capacity over the whole examined area for each urban tissues was taken. The great difference of wind energy capacity over different urban morphology features and different wind inlet directions confirmed the important impact of urban form on wind potential layout.*

Key Words: *urban morphology, CFD, urban wind energy.*

Introduction

Increasing need of energy resources and great environment problems caused by over-used fossil fuel, demand for the development of renewable energy. Wind electricity as a relatively cheap green energy has been well developed over last two decades. According to the Eurobserv'ER Database, global wind power capacity at the end of 2013 has been multiplied by 18 times from 2000. However, most of the wind turbines are located in rural or off-shore areas. Favorable zone for future development is getting fewer and fewer. Their extra drawbacks like over-production for accessible consumers and great loss in long-distance transportation, propel new wind energy adapted to urban environment. In fact, some European countries have made great efforts to the research of wind energy for built environment since 1990's. In 1998, a project named WEB (Wind Energy for the Built Environment) was launched and a new architectural and aerodynamic model was invented as the prototype of UWECS (Urban Wind Energy Conversion Systems) (Campbell and Stankovic, 2001). Later, another European Commission project named WINEUR (Wind energy integration in the urban environment) were elected for more detailed investigation of wind energy development in an urban environment, like suggestions for turbine installation, economic analysis and detection of potential social problems of small wind generators in urban areas (Cace et al. 2007). Apart from the projects mentioned which are rather oriented towards an overview of the real world situation (market, policy, social and economic

aspects), other research has explored the technical domains such as wind turbine design and application (Mertens, 2006; Chong et al., 2013).

With the great rugosity of urban context, urban environment usually has great turbulence and low velocity. However, some special building configurations can have concentrate wind flow, e.g. building edges, passage between two buildings. Research found that, ‘the concentration effect of buildings and the heights of buildings could enhance wind power utilization by increasing the wind power density by 3–8 times under the given simulation conditions’ (Lu and Ip, 2009). High buildings are among the most favourable sites to capture wind energy, where the wind can be much stronger and less turbulent than lower levels. Increasing researches are aiming at roof mounted wind turbines (Blackmore, 2008; Mithraratne, 2009; Ledo, 2011; Balduzzib, 2012; Bashirzadeh Tabrizi et al., 2014) and high-rise building wind catcher (Lu et al., 2009; Poh and Fazlizan, 2012; Lu and Sun, 2014). In addition, new wind turbine technology like Darrieus Turby model, and some successful examples of architecture integrated wind turbines like Strata SE1 tower in London, have shown great confidence for future urban wind energy.

Urban morphology is the study of urban form, which is defined by Kevin Lynch as a part of generally identified urban area corresponding to a homogeneous area in morphological point of view (Lynch 1960). As great urbanisation processing and complex urban system immersing, urban morphology becomes a popular and effective method in the domain of urban planning. Like the built form, urban form can also be determined by two forces: physical and non-physical environment (Sharag-Eldin, 1998). In fact, in the physical environment, urban form is a important impact in city problems like energy consumption and development (Ratti et al., 2005), wind comfort (Bottema, 1993; Ng et al., 2011), air pollution (Edussuriya, 2006; Sun et al., 2012), etc. With the development of Computational Fluid Dynamics (CFD) technology, wind simulation in complex built environment is becoming possible. Even though there exists still problems like turbulence model instability, inexactitude or divergence, many numerical simulations work well and validated by wind tunnel results. Actually, some Best Practice Guidelines (BPG) have been given for the case of wind flow in a built environment by researchers through their rich CFD simulation experiences (Franke et al., 2004, 2007; Tominaga et al., 2008, Blocken et al., 2007, 2012). With CFD simulation, Campos-Arriaga (2009) analysed the optimisation of wind energy development for a specific urban site. Bell (2011) has explored more on wind energy development in urban environment like CFD simulation, turbine design and some sites evaluation. All these literature will be a good reference for our further research on wind energy development with urban morphology. In this paper, a well used CFD code -- FLUENT is used for analysing the impact of morphological indicators on wind flow around some idealised urban tissues, and then some real urban tissues in community scale were chosen for more presentation and discussion.

Simulation settings and validation

To ensure a satisfactory result of a simulation, reasonable settings are of great importance. In this sense, a careful parameter study of CFD code was taken before start a simulation for urban morphology. Actually, a benchmark was applied with one of the wind-tunnel experiments performed by the Architectural Institute of Japan (Yoshie et al., 2007). The test model was a building of width 5 m* length 20 m* height 20 m with a scale $R_s = 1 : 100$ for the tunnel test. Inlet flow data was simplified as a power law:

$$U = U_0 \left(\frac{Z}{H_0} \right)^\alpha \quad (1-1)$$

where U is the inlet velocity at height Z , $U_0 = 7.84$ m/s is the reference velocity (horizontal, of axis X) at height $H_0 = 100$ m and $\alpha = 0.25$ is the power law exponent. There were 109 test points in the central vertical section parallel to the wind (Figure 1).

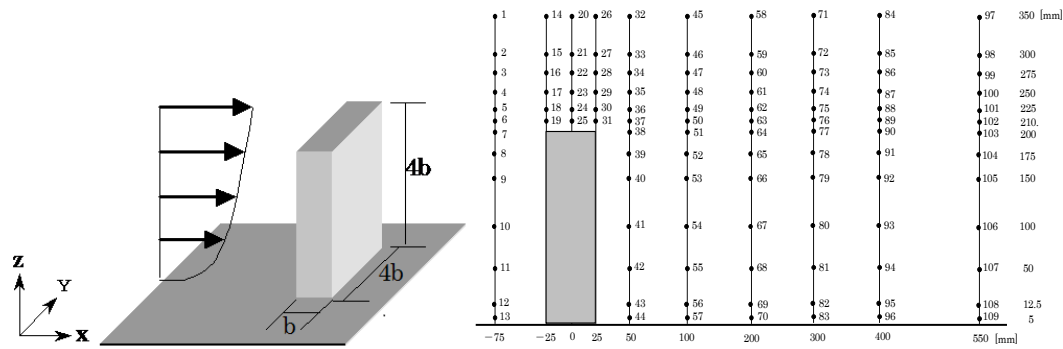

Figure 1. Schematic view of tunnel test model (left), vertical section (Y=0m) and its 109 test points (right)

The ANSYS 12.0 Workbench integrated with FLUENT was used for the CFD simulation. 57 tests were conducted for choosing the proper parameters in geometry, mesh, boundary condition, turbulence models and solution method. Best parameters were chosen under the balance of time cost and comparative errors. $k - \epsilon$ Standard model for the turbulence calculation with double precision and 2 order discretization solution were used finally. The diagram of *Figure 2* is a velocity comparison in the central-line section between the ones measured in the experiment and the ones calculated in the CFD simulation, applied with the best parameters found from the study. Note that the horizontal distance from the vertical base line (grey, where locate the test points, as also shown in *Figure 1*) represents the magnitude of the velocity and a reference length of 5 m/s is given. Results to the right of the base line signify positive values and results to the left are negative. Agreement between the CFD simulation and the experiment is generally rather good. Then these parameter settings were maintained for forward simulations, except for some necessary adaptive modifications like domain size change or mesh number control when modelling a large urban form.

Figure 2. Velocity comparison between experiment and CFD simulation in the vertical section.

Simulation of idealised forms

Before working with actual complex urban tissue, some idealised models were considered to analyse the relationship between the wind flow and building configuration. Here a test reference model with a group of building units (width 12 m* length 30 m* height 20 m) was chosen. Wind domain and building dispositions are presented in *Figure 3*. Note that the group of buildings is symmetrical on the central line, parallel to the wind inlet direction. However, the distances between each row are not all the same. Actually, we did that in expecting for some more various results, as chose the staggering pattern. Wind energy over the roof is the main evaluation object. Two altitudes (5 m and 10 m, over the roof) were considered and the calculation zone was the projecting size of the building plan (*Figure 3, right*). Considering the analysis of the wind intensity over different altitudes with different wind velocity, the velocity rate U/U_H is used where U is the model wind velocity and U_H is the reference velocity in the free wind (same environment but without building) of the same altitude.

Figure 3. Wind domain (left), building disposition in plan (middle), evaluation zone over the roof (right).

Impact of building size

To analyze the impact of building size on the wind flow, we considered five models with different building size (length and width) for all the 24 buildings of each group. Another four models with different size configurations only for the central 12 buildings were compared. An extra model (A') which cuts down the central four buildings each into three small parts in the same environment is compared with the reference model. New building sizes and different densities (building coverage ratio) were given (*Figure 4*). All the buildings are at the same height.

Figure 4. Models in plan with different building size configurations and densities.

By averaging the velocity rates (U/U_H) over all the central 12-building roofs in two evaluation altitudes, the differences among the different groups can be seen (Figure 5): (i) For the modification of fragmentation within the same space, the sum of wind potential over the roof shows less than before (between A and A'). (ii) For the models with different building lengths facing the wind (A, B, C and A', B', C'), the one with shorter length buildings (therefore a smaller density) has higher wind potential over the roofs. Moreover, the wind flow in central zone was greatly influenced by the peripheral buildings, as the change amplitude of the wind velocity ratio from group B to C is much larger than that from group B' to C'. (iii) Among the models with different building widths (A, D, E and A', D', E'), the differences of wind velocity over the roofs are very small, and the changing tendency is not clear. (iv) For the pairs of models with the same building densities (B and D, or C and E), the model with a smaller building length (B and E') has always a higher wind velocity ratio, that is to say, the impact of the building length is much more influential than that of the building width.

Figure 5. Average wind velocity rate for different building-size group models.

Impact of courtyard

To analyze the impact of courtyard on the wind flow, we considered six models with different courtyard configurations in partial or whole of the buildings for each group. The sizes of courtyards and different porosities (compared with reference group) were given (Figure 6). All the courtyards are down to floor.

Figure 6. Models in plan with different courtyard configurations and porosities.

By averaging the velocity rates (U/U_H) over all the building roofs in two evaluation altitudes, the differences among the different groups can be seen (Figure 7): (i) Generally, the models with partial courtyard-buildings (B, C and D) are less windy over the roofs than the reference model without courtyard; (ii) Models with all courtyard-buildings (E and F) are slightly windier than the reference model without courtyard. In addition, the model with small courtyards and small porosity has a higher wind velocity than the one with big courtyards; (iii) Between the models with the same courtyard porosity (D and E), the one with all buildings installed

courtyards is much more windy over the roofs than the one with only partial building installed courtyards.

Figure 7. Average wind velocity rate for different courtyard group models.

Simulation of real urban tissues

Morphological indicators

For the issue of wind energy evaluation, we chose only some morphological indicators that have close relationship with wind flow. Hence, apart from well-known urban planning indicators like Building coverage ratio (CR) and Building floor area ratio (FAR), Average building height, rugosity, Porosity and Occlusivity are used for extra analysis. The definitions are given as follows:

- (1) Building average height, the average height of all the buildings in discussion.

$$\bar{H} = FAR * \Delta H / CR \quad (1-2)$$

where ΔH is the average height of a story, usually taken as 3 m.

- (2) Rugosity, a parameter to describe the roughness of a surface to resist the free wind. Absolute rugosity is the average obstacle height over the whole examined area.

$$R_u = \bar{H} * CR \quad (1-3)$$

- (3) Porosity (absolute), a ratio of the emptiness volume to the entire volume.

$$P_o = \sum_i V_o + k \sum_i V_c / V \quad (1-4)$$

where V_o is the volume of a open space (street, park, etc.), V_c is the volume of a courtyard, k is the openness coefficient of the courtyard and V is the whole canopy volume of the examined urban area.

- (4) Occlusivity, a parameter of the distribution of the built to un-built perimeter against height.

$$O_c = \frac{\sum_N (\sum_i L_b / L_o)}{N}$$

(1-5)

where L_b is the perimeter of a building in the horizontal section and L_o is the perimeter of the correspondent non-built area in the same section, N is the number of horizontal sections. (Adolphe 2001)

Here we choose three different types of urban tissue from three different cities of the world: Barcelona, Toulouse and Bombay. A community scale of 450 m * 450 m is taken for analysis (Figure 8). The information for each form case is given in the Table 1. The general initial conditions are all the same for the three and the validated simulation parameters mentioned above were applied. Local climates were neglected and a 360° round of inlet directions of every 45° were used for analysing an average impact of urban form on wind potential accumulation.

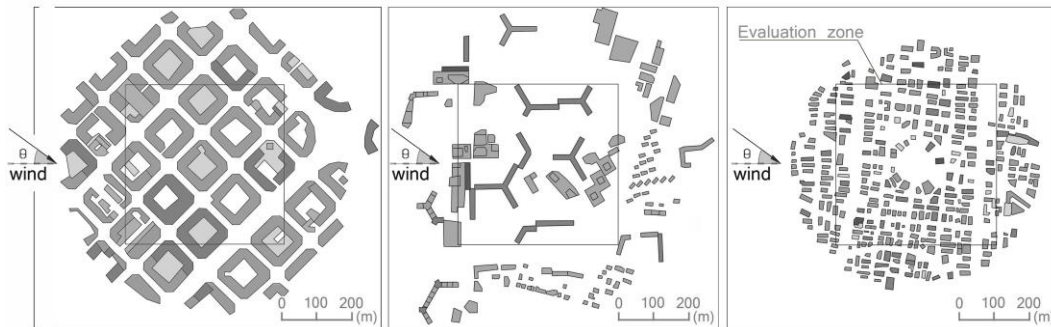

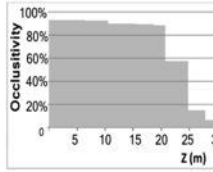

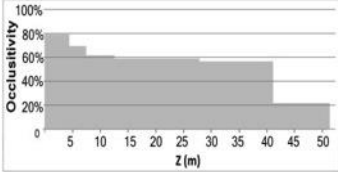

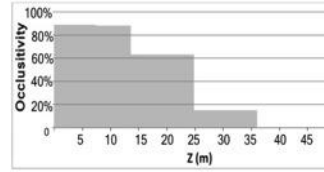

Figure 8. Different urban tissues in plan (from left to right : Barcelona, Toulouse, Bombay).

Table 1. Urban form information for each tissue

	Barcelona	Toulouse	Bombay
Urban form type	City centre core	Collective residential area	Individual building area
CR	56.87%	18.66%	22.08%
FAR	2.94	1.18	1.08
Average building height	18.1 m	21.0 m	16.0 m
Rugosity	10.3 m	3.9 m	3.5 m
Porosity	32.04%	68.26%	78.64%
Occlusivity (relative)	21.27%	26.71%	20.12%
Occlusivity (absolute)			

Simulation result and analysis

As the accessible wind-exploitation heights and areas for different urban tissues are all different, only comparison of wind intensity (as evaluated by the wind velocity ratio U/U_H) is not sufficient to describe the wind capacity of a certain urban tissue. Then, we tried to evaluate with another indicator: Total wind capacity. As we know, wind turbine power is given by the equation:

$$P = C_p * 0.5 * \rho * A * v^3 \quad (1-6)$$

where C_p is the coefficient of performance, ρ the air density, A the area swept by the blades and v the free wind velocity. Therefore, in our case, to evaluate wind energy, a simplified indicator M was defined as:

$$M = \sum_{i=1}^n (A_i * v_i^3 \theta) \quad (1-7)$$

where A_i represents the area of the corresponding velocity v_i . For the wind capacity of an urban tissue, here we only consider the wind potential at a certain height over the roof. From the code FLUENT the area-weighted average wind velocity on the defined planes areas over the roof of those wind-promising buildings (usually the highest buildings) can be found directly. In addition, with the corresponding planes areas calculated in the software AutoCAD, the indicator M for different urban tissue at the height $Z = 15$ m (15 m over the roofs) were figured out (Figure 9).

Figure 9. Comparison of wind potential capacity for different urban tissues.

From the Figure 9, it can be seen that: (i) 1. The wind capacity in the urban tissue of Barcelona is much higher than in the other two. This is due to the large gap over the accessible roof area and roof height. In fact, from the Table 1 we can see that the CR and FAR of the Barcelona urban tissue are both around 3 times of those of the other two cases; (ii) The wind performance from different inlet direction is clear for each cases: the best inlet angles for Barcelona case are -165° and 15° , while for Toulouse case they are -120° and 150° , and for Bombay the 15° and 150° ; (iii) The ratio of the amplitude to the average M value can be found out: Barcelona 28%, Toulouse 50% and Bombay 38%. In fact, according to the impact of urban morphology on wind direction, it reveals the different anisotropic properties among these cases, with the anisotropy level from high to low: Toulouse, Bombay and Barcelona.

Conclusion

Based on a parameter study with a reference wind tunnel experiment, the choice of turbulence model and other parameter settings of the CFD code are validated. Then the paper conducted a series of idealised models with a group of 24 buildings, in search for the impact of building size and courtyard on the wind energy layout over the roofs in the semi-urban environment. Main results include that: (i) the impact of the building length (facing the wind) is much more influential than that of the building width; (ii) the fragmentation of building form within the same space hinders the wind flow; (iii) to ensure a big sum of wind energy over the whole area, courtyard should be distributed evenly rather than partially. At the same time, the wind energy outcome shows no linear dependence to the courtyard size.

Furthermore, three real urban tissues were chosen for morphological analyse and wind potential evaluation. Results of different wind capacity values over different type of urban tissues and in different wind inlet direction, confirmed the great impact of urban morphology. Some macro character of the urban tissue like anisotropic property is discussed. For future work, more types of urban tissues would be considered and more morphological properties like porosity can be discussed for better contribution to the wind energy development in urban environment.

Heritage, infrastructure, structure and urban form. Challenges for Brazilian historical cities and/or colonial matrix

Adriana Nascimento, Marcelo Silva

Departamento de Arquitetura Urbanismo e Artes Aplicadas, Universidade Federal de
São João del-Rei. Rua Maestro Batista Lopes, 147 – Tejuco São João del-Rei/ Minas
Gerais, CEP. 36300-176. E-mails: adrianan@ufsj.edu.br, sil_marcelo@yahoo.com.br.

Abstract. *In this paper we propose to glimpse potentialities and challenges as a process and acquiring meanings for the construction of others and news practices related to what you can name common and also the uncommon. Taking considerations about the relationship between infrastructure and structure, the presence of collective educational equipments in the urban form with heritage sites, we propose to inquire the ways that the urban investments can and should happen to subsidize the sense of the common as the uncommon. How can conceptual delimitations and/or definitions of the territory, as heritage area limit and/or expand the fields of action? In which way can we apprehend, transform and reconstruct practices, uses and functions with distinctive and different parameters for the common sense? Which future and common in terms of urban morphology can we put as necessary and unpredictable? In Brazil, the challenges are related to the infrastructure and the urban structure on the measure that it would be the elements that can allow cohesiveness as urban quality. This is an attempt to indicate parameters to give an orientation to take decisions in the direction of the common and the uncommon future.*

Key Words: urban morphology, heritage, infrastructure, urban planning.

Introduction

This paper / essay seeks to relate the general theme of 21st International Seminar on Urban Form: *Our Common Future in Urban*, with the specific theme *Multidisciplinarity in urban morphology: The formation of new areas of knowledge* and also to research, education and extension works we developed in the last five years.

We believe it is important to point out that since we start our studies in Urbanism (PROURB / UFRJ) and Urban and Regional Planning (IPPUR / UFRJ), our approaches have been directed towards multidisciplinarity, thinking about limits and challenges not only as theoretical but practical and therefore real.

Another pertinent question to be placed here is about our professional and academic experience that have been displaced from large scale (Metropolitan, Rio de Janeiro / São Paulo axis in Brazil), triangulating towards vector internalization southeast toward Belo Horizonte, for the medium and small scales, although considered regional scale (Brazilian and also the state governamental one) by we became professors at the Architecture and Urbanism Course at the Federal University of São João del-Rei¹⁷² in Minas Gerais. This change of scale-space-time show problems in complete different points of view, notably the real and particular ones of the city and the region.

¹⁷² Course implantation with beginning in 2009, we serve coordinating (ATA-UFSJ) and engaged with Groups (LAUS and OBEDUC) in Research Projects involving multidisciplinary themes related to urban and public spaces, as well as thematic studies of form and urban relations via guidance for the production of different surveys and preparation of unpublished reports on SJDR, both associated with the teaching, as with the extension projects.

Taking into consideration the relationship between infra and structure, the presence of collective educational equipment in the *urban form* (Panerai, 2009) with heritage sites (Choay, 1988, 2006), and their preservation and transformation, we intent to raise questions on the *ways* (Nascimento, 2009) that the urban investments can and should happen to subsidize the sense of the common as the *uncommon* (Pietromarchi, 2005).

The diverse experiences and practices of urban management can contribute as parameters to think about how to proceed in this direction. However, based on our studies, including some conducted on specific SJDR sites, we understand that it is not just playing with unquestionable practices and processes, but rather develop tools and instruments to contribute in fact to the quality of life of the population, as with the urban morphology.

These factors, inseparable in our view, could contribute towards thinking about the city and its intersectoral issues. Thus, we ask:

Which future and common, in terms of urban morphology, can we put as necessary and unpredictable?

Another inevitable approach proposed here concerns the interrelation between urban and cultural production, between *action* and *work* (Arendt, 1972; Nascimento, 2009), and accordingly, forms spatiotemporal *structured* and *structuring* (Bourdieu, 2002) and therefore, infra and structural.

Regarding the methodological question of scope developed here we start from morphological debate associated with that presented by Lefebvre (1995 [1966]) on *formal logic*, as well as a selection of authors from diverse disciplinary fields, in order to contribute to a multidisciplinary approach to spatial question (CHOAY, 2006) still in process, not only in our studies but also for approaches that seek to extrapolate and reevaluate such notions in a formation field – multidisciplinary - (Panerai, 2009; Bourdieu, 2002; Krauss, 1984) and bringing further contributions to enable the theme proposed herein.

This way, we propose to glimpse potentialities and challenges to be faced as a process and acquiring meanings for the transformation and the construction of others and news practices related to what we can name the common and also the *uncommon*.

Heritage

As we understand the historical question does not restrict the shape of the city, but imbricates by practices that, appellants, can transform and rebuild the uses and functions in the cities that are beyond the scholars' ones. In which way can we apprehend, transform and reconstruct them with distinctive and different parameters for the common sense?

Thus the heritage question to be crossed by debates that go beyond *levels* and *dimensions* (Lefebvre, 2008) formal and spatial suggested by *letters* and patrimonial practices, which produced mostly in developed countries, eventually approaching the theme of virtually unfeasible mode on your whole, especially economically (Harvey, 2013).

Choay (2006) reinforces what we understand about the aspects and qualities of form, which remain to be desired on spatial values in everyday life. Thus, studies of urban morphology continue to have effect (Panerai, 2009) not only for their technical character, but especially by those speculative, not in the financial sense, but analytical and purposeful.

In fact the issue of Brazilian cities that arises is adversely and simultaneously in construction, given absences and distances between theories and practices, between formation and apprehension, between public policies and management.

The speed of change in the urban form is disparate in relation to political and cultural debate in recent decades in Brazil and is not synchronized and much less associated with positive changes. Even the creation of forums for heritage debates not yet cover a broad and coherent manner, either by training distances, by practices and oversight.

By stating that there was a direct relation between the action, the work and the product Hannah Arendt (1972) lead us to understandings about the senses of action from critics and

doubters placements. Using the *distinction* and the *direction* of actions, Arendt tell about the differences concerning the consumption and the expression from the senses of actions, of memory and the subjective investments.

Thus, attempts to preserve in SJDR end subject and related only to the shape of the buildings and their interiors, without considering broader urban and spatial aspects - related to the built area on the lot, the relations established between solids and voids, forms and content¹⁷³, which also correspond to the time-space questions.

How conceptual delimitations and/or definitions of the territory, as heritage area, can limit and/or expand the fields of action?

Urban Form

The question of urban formal logic / morphological in this paper seeks to address the multiplicity of possible and able relations to allow dialogues between different urban areas: central, transition, and expansion of the urban edges, because they all belong to the urban form and if that is not clear, there could bring about many mistakes.

Studies carried out over the city of Sao Joao del-Rei generally have almost exclusive visions about its historical centrality, under a nostalgic ideology, which was lost, somehow throughout the twentieth century and, as if it were a unique temporality and exclusionary related to the colonial matrix of Portuguese origin. Despite all attempts at preservation in the city, these are limited to the historical center and emphasize fleeting urban readings, and that does not even include any guidelines or debate about the intangible.

This understanding of what takes place on and in the historical city and its shape is not repudiating the meager attempts to rescue significant cases. However, it ends up being restricted to a matter of class and / or elite that invests to possess the means to maintain assets. Actions developed by the city managers organs to meet the different levels and dimensions of the problems correspond to isolated attempts and staggered by the lack of data, studies and by not being configured as projects, plans or government programs.

Thus, the urban form when restricted to its historical centrality and exclude other spacial temporalities and temporary uses ends up losing indispensable qualities of the common.

Understanding¹⁷⁴ and imagining studies of urban form associated with planning are able to add other parameters to formal. They are geared to meet both legislative deficiencies, as the practices and which relate to other inputs such as socio-economic-cultural basic data, urban density and registration (enrollment) permit match the plural circumstances present over time in urban structure, and may in fact contribute to a broader and more comprehensive joint.

On the Brazilian case and its historical cities, we understand that the challenges are related to the infra and the urban structure on the measure that it would be the elements which can allow cohesiveness as urban quality. It isn't just about quantity, but also about qualities, in a lathing between time and space (Rossi, 1988; Argan, 2005).

Infrastructure and structure

The separation between infrastructure and structure is not out here on purpose. It has an immediate-mediate and / or progressive-regressive intention of moving both exposed by Lefebvre (1995). We understand that the terminology composed infrastructure is precisely its interconnection and / or juxtaposition of complementary issues. However, we understand that as

¹⁷³ The debate about the relation form-content appears both in our dissertation, as in the article written for the PNUM 2013.

¹⁷⁴ Observations on the experiences acquired during the period from 2010-2012 in which we operate as a representative member of the UFSJ in the City Council Preservation on Cultural Heritage of São João del-Rei.

separate categories, they remain virtually treated in urban reality of Sao Joao del-Rei, contributing to the senses brought to their understandings. They could be treated alone at first, then to be reconnected and therefore practically transformed.

It is a process of reframing, and hence, formation, auxiliary to what relates to what refers to the structure as a basis, and the infrastructure associated with the above, or to what outside or on the surface would relate to buildings and equipment intended for use and functions of the collective (Choay, 1988).

In the relation of infraestrural question in Brazil, we understand that the precariousness and the improvisations even with legislative efforts and instrumental approaches for updating qualitative and quantitative transformations, still necessary in large scale.

Thus, the debate proposed towards the Right to the City (Lefebvre, 2001; Harvey, 2013) remains today, especially in what corresponds to the urban and existing centralities, as well as other, not recognized, still in process and / or under construction, even without local planning and / or immediate needs.

Concerning the position of the central location of certain associated community facilities to public spaces, it is important to bring to the debate a case study of one of the first public schools established in the city of SJDR, located in the historical fabric.

As structural and structuring element of urban space it could serve as an educational parameter both for their formal, spatial and property aspects. However, what might serve the most expensive formation of intentions through comprehensive education, to be devoid of its qualities and mischaracterized spatially contributes only in its most primary sense: as a place of shelter.

Relation to equity, infrastructure and urban form is treated as a separate thing, we hardly chance for some less common and very unusual, especially in cities, for its historical richness, still preserve memories, tangible and intangible, in shares, plural times and spaces.

Challenges for Brazilian historical cities and/or colonial matrix

Regarding challenges for Brazilian and / or colonial matrix historical cities, due to distance and the gap between rights and duties (Nascimento, 2011), between theory and practice, between infrastructure and structure, these are many.

Our approach is *tentative* (Bourdieu, 2002 ; Lefebvre, 1995) to indicate parameters that add time and space, that means to give an orientation to take decisions and, finally, of practices that can be in the direction of the common and the uncommon future, because it's not done yet.

In addressing urban and local-global issue, not global-local, we believe pointing directions and questions about weights and values that different in its various scales and speeds allow, if placed on the agenda, scroll and break with hegemonies.

There it comes, bearing simple challenge, but above all, necessary utopias (Ribeiro, 2005; Lefebvre, 2008). Utopias as answers to consider the actual and possible (socio-economic and cultural) in the plural sense, spatial, urban, common and unusual qualities.

Abstract. *This article focuses on the relations between the Morphological Structure and the System of Community Facilities at several scales of the human form, seeking the understanding of connections and possible interdependency between the two systems. Starting from the conceptualizations of Urban Morphology and System of Community Facilities discusses the case of the city of Navegantes in the coast of the State of Santa Catarina, southern coast of Brazil. In regards the said city, one can identify that the understanding of its formal structure related to the system of community facilities leads to the deepening knowledge of its present urban form and future possibilities. Furnishes both the verification of its spatial patterns in several scales like listing situations and locations where new community facilities and spatial patterns would potentially be capable of establishing new and qualified relationships between different scales. From one side one would have better conditions of attending the basic needs of the population, in which the devices are essential providing, possibly, an increase in the quality and vitality of urban life. Of another, it would strengthen urban structure, able to potentiate the permanence of meanings and identity of the city.*

Key Words: *Community facilities, urban morphology, city of Navegantes.*

Understanding the urban morphology

The importance of urban morphology and its verification is acknowledged by the majority of scholars of urban form. But the conceptions of what a morphological study is are not coincident, but the conceptions of what a morphological study do not coincide, there being a diversity of definitions and understandings on how to approach the form on which elements should be studied, and on which are the possible and necessary analysis for the recognition of shape.

The morphology one can say is initially related to what is seen - to the appearance - or by what our visual perception appropriates on the immediate level, since the shape is what first, generally, amazes our senses. This seeming aspect of things refers to an arrangement of objects, a pattern or structure or formal organization that can be interpreted and where we can identify the presence, the potentiality and capacity for social life.

We highlight our understanding of the city as one of the most important patrimonies and property of the material culture which in its great inertia acquires social factor conditions, and not only a result or consequence. The permanence of forms is crucial on this issue, by being one of the most remarkable features of form phenomenon, which makes it also be, an agent in the relation between crystallization and Changeover of social life. The city, seen as asset of material culture, is a structured form, where situations and places - with different durations - compose the dynamic (and the tension between) of permanencies and changes that creates and recreates the meanings and identity of the city. In the analysis and in the city intervention, understanding it as in a constant and dynamic social process, the form cannot be seen as an isolated phenomenon, because, historically, it is both a consequence and factor of evolution or transformations.

‘For the definition of the scales and the elements to be investigated, and at last, for the understanding of urban form, one should understand it as an extensive phenomenon and, at the same time, with local occurrences, from which elapses the morphological study on the global scale and on the scale of parts and, furthermore, one must consider the growth issue and historical development.’ (Assen de Oliveira, 1993: 24)

In the range of this essay, we embrace the study of morphology and identification of morphological structure through the study of relations between emptiness - the natural elements, the trace, the micro and macro subdivision and full - the buildings, their typologies, uses and collations, in order to identify the morphological structure of the city and speculate its relations with the location of equipment.

Thus, at the survey conducted that provides support for this essay, on the study of relations between morphological structure from the City of Navegantes, located on the south coast of Brazil, and community facilities it was used a methodology for morphological basis, denominated "Method of Apprehension of the city", developed by Professor Dr. Silvio Sawaya, in 1991. The choice to this method came from the premise of a method that enabled morphological analysis, without leaving aside other essential issues to the understanding of the city - Usage flow laws, regulations, appropriation and meaning.

This way, the method gives support to the morphological analysis, allowing a work of thorough research, focusing on the community facilities system, spaces that are seen as permanent in the city. The application of this method permitted, in the first moment, an analysis throughout the understanding the four layers that compose it: morphology, permeability, legitimacy and fundamentality to, in a second time, as a result of the crossing of layers previously studied, listing situations and locations where new community facilities and spatial patterns would potentially be capable of setting up new and qualified relations between different scales.

The implementation of the method of Apprehension of the City starts from the premise of the relation between the part and the whole, where the whole is not the simple sum of its parts, but on the contrary, they both contain themselves. Furthermore, it is argued that it is from within that one can visualize the set with greater clarity. The case of the City of Navegantes has had the understanding of the morphological structure of the city on its "whole", and the in-depth study of community facilities in the "part", comprising the subsystem for education equipment.

Understanding the system of community facilities

Aymonino (1975:49) presents the buildings as community services designed to meet the needs shown by the services, in other words, the specific needs of a particular society. Additionally, the emergence of equipment is in its relation to the services, since these two variables should not be analyzed separately. Meanwhile, these needs vary over time, according to the particular interests of such society. These amendments are connected to the transposition of a need or individual interest in collective, as one can also claim that the inverse is true.

Aymonino (1975:47-48) brings the definition of services proposed by GESCAL¹⁷⁵ center, however, argues as more pertinent the definition for services that brings the Italian Encyclopedic Dictionary, in which public services are divided solely on special and general services. Special services are defined by individual benefits that are paid by each user individually. Now general services have the concept of the collectivity in which the services are funded by taxes from such community.

It seems, therefore, more logical to set as service all appropriate elements to satisfy different human needs in a certain society, introducing, in the first place, a distinction by private or public qualification, thereby establishing a legal reference of the forms of property, appropriation and management. (Aymonino, 1975:49)

In Brazil, the subject of typification and definition of Equipment is treated in rules and legislations. The Rule NBR 9284/86, entitled Urban Equipment, defines them as being "todos os bens públicos e privados, de utilidade pública, destinados à prestação de serviços necessários

¹⁷⁵ GESCAL Laboratoty (Gestione Case Lavoratori), considers community facilities elements defined by its public character. This characterization brings the subdivision of the equipment according to the needs they aim to satisfy. (Aymonino, 1975:47)

ao funcionamento da cidade, implantados mediante autorização do poder público, em espaços públicos e privados.”¹⁷⁶ The rule does not distinguish urban from community equipment; it treats them as "urban facility" and subdivides it into a few categories and subcategories, according to their function.

The Rule NBR 9284/86 proposes the categorization of the equipment in: Circulation and Transportation, Culture and Religion, Sport and Leisure, Infrastructure (Communication Systems, Energy System, Public Lighting System, and Sanitation System), Public Safety and Security, Public Management, Social Assistance, Education and Health. Likewise NBR 9050/2004, revised in 2005 laying down criteria and technical parameters that must be observed on conditions of accessibility to public places, it also treats the equipment in a unique way, as Urban Equipment. Torres (2000) also adopts the definition of urban equipment, not to mention the term community facility, as the material support for the provision of basic health services, education, security, sport and leisure.

The Federal Law No. 6766/1979, in its Chapter II brings a distinction between community facilities and urban facilities. The Article 4º, 2º Paragraph, defines community facilities as being “os equipamentos públicos de educação, cultura, saúde, lazer e similares”¹⁷⁷. Article 5º, Single Paragraph, considers as being urban facilities “...os equipamentos públicos de abastecimentos de águas, serviços de esgotos, energia elétrica, coletas de águas pluviais, rede telefônica e gás canalizado”¹⁷⁸. The Federal Law 10257/2001, known as City Statute (Article 2), employs the same categorization about guidelines on Urban Policy, “...oferta de equipamentos urbanos e comunitários, transporte e serviços públicos adequados aos interesses e necessidades da população e às características locais”¹⁷⁹.

Besides these conceptualizations of urban and community facilities, Célson Ferrari (1977:417), characterizes as equipment material spaces that materialize the institution. So, to the author, the areas of urban space occupied by the material equipment of the institutions are referred to as institutional urban land uses¹⁸⁰. It is observed that, even though the legislation, at least since 1979 set as urban facilities only those from urban infrastructure and, as communities, the equipment for collective use by the community, Brazilian Association of Technical Standards makes no such distinction. Yet, unanimously, the authors consulted distinguish between infrastructure and community facilities adopting the term "institutional use" proposed by Ferrari (1977).

Exploiting the facilities location in the morphological structure of the City, Panerai (2002:215) states that the program definition depending on terrain must incorporate, beyond quantitative issues, such as volumes and distances, issues regarding to hierarchy to the city in relation to the immediate surroundings, with accessibility, in other words, questions concerning the monumentality and limits. Gouvea (2008) adds that “Equipamentos comunitários são elementos essenciais para o funcionamento da cidade. Sua localização na malha urbana deve obedecer a uma relação de uso (cotidiano ou eventual) [...]”¹⁸¹.

Aymonino, already in 1975, showed concerns about the location of community facilities at the city structure, with exposition of the concept of "edification typology" in its relation to the urban form as a guide for the insertion of these facilities location in space. The analysis field of

¹⁷⁶ "All public and private properties, of public utility, for the provision of services necessary to the functioning of the city, implemented upon authorization of the government, in public and private spaces." (translation of authors)

¹⁷⁷ "public facilities for education, culture, health, recreation and similar" (translation of authors)

¹⁷⁸ "... public facilities of water supply, sewerage services, electricity, rainwater collection, telephone and piped gas network." (translation of authors)

¹⁷⁹ "... supply of urban and community facilities, transportation and public services suitable for the interests and needs of the population and local characteristics" (translation of authors)

¹⁸⁰ Celson Ferrari divides institutional uses in: Education; Social, cultural and cultural; Recreational or leisure; Administrative.

¹⁸¹ "Community facilities are essential elements for the functioning of the city. Its location in the urban area must obey a relation of use (daily or occasional) [...] ". (Translation of authors)

the concept formation "edification typology" displayed by Aymonino (1975) takes place from the eighteenth century, period of the industrial city (capitalist-bourgeois) that constitutes the matrix of the contemporary city. (Aymonino, 1975:96). The study of the slow process of activities characterization allows to identify origins of what was defined by Aymonino as community facilities, and the emergence of new necessities - determined by economic, political and social development of a society historically defined, bourgeois society - that over its development convert into organized and socially necessary activities.

When these activities reach in their organization, a more complex and articulated stage, with the tendency of turning into permanent activity, in other words, stable over the years, there is a need to define a suitable space, able to consolidate and develop certain activities through the same architectural expression. Only then one can speak of equipment, such as the original nucleus of the modern "edification typology" non-residential character (Aymonino, 1975: 97 and 98).

When addressing on typology, its concept and formation, Aymonino (1975) adds that a very positive aspect of modern functionalist movement was an extension of the thematic related to residential relations, as a way to address the problems of flow, and function. Now the buildings facing the community facilities need, the author argues, to transcend the issue of typology and be conceived in accordance with the surroundings is to result in an architecture that stands out or simply shapes to the existing, but mainly incorporating cultural and symbolic characteristics of society and location.

On the typology Argan in 1963 already envisaged that the type is materialized in the reduction of a complex of formal variants on a common basic shape.

By having the reduction of formal variations to a basic form to suit certain activity the building is disclaim of all symbolism and identity, even considering that the creation of the type is the synthesis of a complex of ideological demands or practices related to a certain historical situation in a given culture. Priority is given to meeting the needs through the activity such edification will perform. These considerations are of great value so that the insertion of community equipment has not been referenced only to the preconceived architectural typology, but the issues related to structure of the city, the relationship with the immediate surroundings, to its accessibility and potentiality of appropriation and meaning.

Contextualizing the City of Navegantes – SC

The city of Navegantes is located in the Micro-region of Itajaí, and form a continuous area of urban occupation and socio-economic logic that makes it highly representative, both regional and national (Figure 1).

The recent growth in the region, especially after the 1990s, understood as a reflection and social condition of the duplication of BR-101, influenced so that Navegantes International Airport became the second passenger terminal of the State. And, according to Infraero and information obtained at City Hall, the airport has already a project for its amplification and 70% of the necessary area already expropriated. The city also received a major investment with the implementation of the port terminal of Navegantes in the opposite bank of the port terminal of Itajaí.

The city has twice the population of the State cities average, corresponding to more than 60 thousand inhabitants by the count in 2010, which places it in 20th place, with density of 543.29 inhabitants / km², in addition to placing, in the period of 1991-2000, it has become the fourth city with largest demographic growth of the State, way above even the Brazilian average growth, explained by the recent implementation of the port terminal and industries of cutting edge technology connected to logistical issues brought by the Port.

Figure 1. Area of Urban Occupation in the Micro-region of Itajaí.
Source: Schäfer, 2009.

The data of population growth in the State of Santa Catarina show a large growth in the period 1991-2000. In the period 2000-2010, as predicted, but not as rapid as verified in the previous decade. However, even with the annual growth rate reduced and stabilized, the city of Navegantes presents an annual growth rate of 4.41 %, indicating a tendency of the city's population more than double, in the year of 2030 (a period of 20 years), reaching more than 143 thousand inhabitants.

The city of Navegantes has great economic representation, with a high GDP and a growing population rise. Though, it presents a Human Development Index extremely low compared to other cities of the micro-region and, even, nationally. The low level of human development can also be explained by the data on poverty in the city. The incidence of poverty in the city of Navegantes, according to IBGE (2010), shows very high, including if compared to other cities in the State of Santa Catarina, being the fourteenth city with the highest rate in the order of 38.20%. Compared to the cities of its micro-region, it is a city with the highest index. Thus Navegantes presents demographic rates on the rise, an extremely representative economic profile in its micro-region, but it has a condition of extremely low medium human development, indicating little income distribution, little longevity and low indexes of education.

The period that understands the evolution from 1970 to 2000 the city of Navegantes accrued an evolution of 80.8%. The biggest step forward was recorded in income dimension, than the same period grew by 215.7% and the lowest evolution was registered in education dimension, which grew by only 48.4%. This condition heeds to the understanding of the system of community facilities, with emphasis on education subsystem and its intersection with the morphological structure of the city.

The crossing of morphological structure system with community facilities

The structure of the city of Navegantes is verified with the aim of identify, fundamental areas in its configuration, containing the relation between permanencies and changes. The fundamental and most enduring components represent the structure of the city and, usually, are related to spaces for common use or the symbolism and identity that may be acquired to people and city residents.

“Toda realidad puede ser estudiada por meio de su estructura. La ciudad es uma realidad compleja: um hecho, uma experiencia e uma ideia. Es historia y proyecto, forma, lugar, lenguaje y cultura. Todos estos aspectos también pueden revelar su estructura.” (Munizaga Vigil, 1985 apud Munizaga Vigil, 1998:27)

When applying the method of Apprehension City, it was identified that the main structural morphological elements of the city, are: the conditioning of the hill covered with vegetation, the line of the Atlantic Ocean, the serpentine line of the river and constructed elements, airport and port (Figure 2).

Figure 2. Schematic Morphological Structure of the City of Navegantes.
Source: Authors.

These elements seem to organize the growth of the city, representing the trend of expansion of earth built, which in turn seems to have the same logic of the growth of centralities. These elements seem to organize the city's growth, representing the expanding trend of the built mass, which in turn seems to have the same logic of the growth of centralities, the direction of flows and including the possible expansion logic of the system of community facilities (Figure 3).

It being the main elements that structure the city, represented in Figure 2 that reflect the morphological structure, summarizes other forces of fundamental importance for the city. (See Figure 4) The key elements are generally related to spaces of common use, and thereby the centralities-recognized as capable of containing the diversity and superimpose flows, uses, activities, people, cultures- show themselves as places where collective happens and ownership is recognized, even in Navegantes, at centralities are present the community facilities.

Figure 3. Schematic Axes of concentration of community facilities and possible expansion logic. Source: Authors.

Figure 4. Synthesis of the City Structure. Source: Authors.

The forces of fundamental importance to the city of Navegantes and, therefore, structural shape of space are related to morphological configuration. These forces are:

Natural elements

In the case of Navegantes, Itajai-Açu River, the hills and the Atlantic Ocean are the major natural elements that, apart from being structuring elements and conditioning of the landscape, play an important role for local identity and symbolism. The city has emerged on the banks of Itajai-Açu River, which served as basis for the livelihood of fisherman families that lived there and, currently, this natural element supports the development of fishing industries, shipyards and the port which provide the city one of the higher gross domestic products of the state.

Moreover, the river also provides the city an extremely distinguished landscape by its serpentine motion, which is reflected in the urban occupation area. Itajai-Açu River is an element of the morphological structure, for permeability and also due to these historic features and presented identities.

Navegantes, when bathed by the Atlantic Ocean, gives rise to a waterside leisure and entertainment. The boardwalk built by the sea, along with the equipment that supports this axis, is the main attraction, for both tourists and locals.

Existing centralities and a New Centrality proposed by the current Director Plan

The superposition of scales, flows and uses provide to existing centralities a character of dynamism and enrichment of public space by the diversity of activities being developed there. All existing centrality are arranged by a main shaft, of morphological importance as well structuring the morphology, from which it has been branching along the same track or others connected to it.

Among the verified centralities stands out Downtown, besides the importance in the uses and flows of the city, also possesses characteristics that legitimize its importance in the city scale by the symbolic and identity character representing the citizens of Navegantes. In it are encountered the Square and the Church of Nossa Senhora de Navegantes and the main waterway crossing to Itajaí, town south, through the Ferry.

All existing centralities, besides being under axes of the city morphological structure, contain local scale of community facilities, the neighborhood and regional. The proposal for a New Centrality, by the City Master Plan, strives to overpower the discontinuity of the city urban occupation by reducing the vacant urban areas and, in this way, provide a positive gradation of the built area to natural elements. Another fact that reinforces this New Centrality and asserts itself as a very interesting alternative for the development of the city, as with the expansion of the airport that currently seems to be an accomplished fact (since more than 70% of the area is already expropriated) could create a large segregation between the northern and the southern part of the city.

Ferry, Square and Nossa Senhora dos Navegantes Church

The form has permanence degree higher than the uses and flows, however, some equipment, especially when pegged to public use, show themselves in the city structural areas, also due to its symbolism, they are: Nossa Senhora dos Navegantes Square, along with the church and the Ferry. They are equipment at the scale of the city of Navegantes representing its founder center and, the crossing through the Ferry, coming from Itajaí, the square and the church are landmarks of the space.

At Nossa Senhora dos Navegantes Square, are developed activities and events as Carnival and religious festivals that attract every year thousands of tourists to the region and state.

Port, airport and fishing and shipyards activities

The port and airport condition the urban occupation in Navegantes, are elements that morphologically present major vacant urban in the area. Are mobility equipment of national and international scale which provide great visibility to the city and high economic indexes, and optimize labor supply for citizens of Navegantes.

The tracing and Mobility Axes

BR-101 is a constructed element that has high degree of permanence in the system, as it has territorial scale. Other axes of the trace, with regional scale, form a connections system that promote north-south and east-west links of the city with its neighboring towns, as well as the centrality system and the urban and community facilities system within the city. The degree of permanence of these axes is elevated for being collective use and, mainly, for being public domain, materializing in spaces of way, of living, experience and socialization.

One highlights the importance which tends to take the Estrada Geral in Navegantes - Penha in the new structure that will incorporate the city with the expansion of the airport and the materialization of New Centrality. This route will hold the north-south flow in equal capacity, or perhaps larger than Beira Mar Highway.

Community Facilities System

The Community Facilities System is associated to centralities and is found at the main axes of displacement of the city, which represent the morphological and permeability structure of Navegantes. The sets of Community Facilities System, mostly, have at least some subsystems of uses of such equipment. Subsystems of education, social institutional, health, safety and public administration and leisure are found.

The approach in two educational institutions of the city strove for discussion of community facilities facing towards the inside and with little or no relation to the street public space. The connection between the equipment and the public space of the street is restricted to determined schedules for the ending and beginning of classes for students entering the institution and no longer keep in touch with public space. Being understood that in class schedule contact should be restricted to not disperse students' attention; however in situations of socialization one would be able to have the expansion to public space (Figure 5).

Figure 5. Images of students exit of Elementary School "Prof. Irene Romão": Appropriation and socialization in public space. Source: Authors (2012).

The sizing of Community Facilities from the radius of coverage is a first step to knowledge of the possible influence that equipment provides on the city area. But one must consider, in a second stage, the morphological features, especially the city layout, are of fundamental importance to check whether the equipment can really meet to the radius of influence, as well as the density of the locality. In the case of Navegantes, the parceling is perpendicular to Itajaí-Açu River and Atlantic Ocean and this feature evidences few connections in north-south direction. This condition is a characteristic that should be taken into consideration, primarily for leasing of local-scale facilities, like health centers and kindergartens.

Places of permanence as a basis for the implementation of the community facilities system

The understanding of the city structure, primarily morphological, but also in its relation to the permeability and legibility, synthesized by permanencies and changes, point out the of community facilities system as possible and important protagonist of the city of Navegantes. With its deployment the one hand one would be able to have better conditions of service for the basic needs of the population, in which the devices are essential providing, possibly, an increase in the quality and vitality of urban life. On the other hand, to would strengthen urban structure, capable of potentiate the permanence of meaning and identity of the city.

It is acknowledged the capability that equipment plays attracting people in different scales. Thus, it recognizes that there may be protagonists of public spaces and induce the greater

vitality of the place, but with a few caveats. It is done a merge of activities and uses, as each subsystem of community facilities schedule, which is often defined, on the basis of its complexity.

Understanding the centrality as spaces of permanence in the structure of the city of Navegantes, it is claimed that they provide the articulation between the built environment and the natural environment and, likewise, the implantation of community facilities system, as protagonists of different public spaces which develop at different levels of centrality, are likely to promote reaffirmation of the city morphological structure.

At central areas of Navegantes, can concentrate the equipment designed for the city scale in its different categories of uses, since it is recognized that sociability and the incentive to appropriation of public space occurs with the mix of the equipment activities. Nearby the natural elements have emphasis on large parks with culture activities, leisure and sports, and can meet the festivities of Nossa Senhora de Navegantes and Carnival, admittedly symbolic events and activities for residents.

Setting out a parallel between community facilities system and centralities, it results in a scheme that demonstrates that at maximum occupancy of centralities of Navegantes could develop equipment on the scale of the city and in the same way at the rarefied occupation, on the transition with the natural environment, they will develop the equipment on the scale of the city, including regional. In what represents the core between the maximum occupancy of the centrality and rarefied occupation, on the banks of the natural elements, the equipment would be on the scale of the neighborhood and location.

As it is understood that the rarefied occupation will be related to the natural elements of the city of Navegantes, this condition of occupancy of community facilities system will provide the contact of citizens of Navegantes with both centrality of trade and services (using equipment on the scale of the city as hospitals, cathedrals, administrative uses) as well as city contact with natural elements (with the use of equipment on the city and regional scale, as urban parks, sporting venues, cultural facilities) (Figure 6).

Figure 6. Relation Scheme Centralities x Scale of Community Facilities. Source: Authors.

The opportune places for deployment of community facilities are located along the morphological structure of the city and necessarily must contemplate the mix of trade / service activities, with the residential use, adding up the attractiveness of several subsystems of community facilities (education, health, social, administrative).

It is important to underline that the implementation of community facilities, can strengthen the identity and the promotion of sociability, that almost always associated to the existence of community facilities, such as places Secchi (2003), and that, in its turn, these community facilities (hospitals, cathedrals, schools, markets) are shown as space affirmation of public

space. Besides reinforcing the identity, the community facilities implementation, configured from the structure of permanencies the city of Navegantes, can also be understood as the possibility of providing more representative indexes of Human Development to the city and as an alternative to provide living spaces with urban quality.

Housing development transformation: political directives and post-occupation life

Maria Cristina Teixeira, Marieta Cardoso Maciel, Paulo Henrique Alonso

Architecture School, Federal University of Minas Gerais

E-mail: mcrisvt@gmail.com, marietamaciel@gmail.com, paulohalonso@hotmail.com

Abstract. *The housing policy adopted by the Belo Horizonte City Council over the last 20 years has produced housing parameters that have resulted in standardized buildings grouped together into housing estates. Although conceived and designed by architects, the construction of these buildings does not follow the premises on which policy and project are based. The process does not take into consideration the often accentuated differences in land characteristics of both shape and topography, resulting in large differences between built areas and open spaces. Despite free spaces being large because of pronounced gradients, they are not primarily destined for collective use, but rather they are used to make adjustments on the estates in the form of embankments and green areas. As these housing developments are occupied, the open spaces are transformed and buildings are isolated by fences and walls, compromising permeability, circulation and the internal landscape. In addition, the few spaces attached to the housing projects are used privately by ground floor residents who close them off completely. These manifestations underline the lack of articulation between the parameters dictated by the housing policy and the appropriation desired by the residents. This article intends to investigate the coherence in the relationship between the adopted housing policy and the housing development projects under analysis and will examine the transformations that have been taking place in the post-occupation process.*

KeyWords: *housing policy, project, transformation, housing*

Introduction

This article focuses on the research, "Open spaces in housing projects in Belo Horizonte (MG)", carried out by the Landscape Laboratory at the Architecture School of the Federal University of Minas Gerais (EAUFMG) and sponsored by the State of Minas Gerais Foundation for Research Support (FAPEMIG). The changes that have occurred in the free spaces allocated to housing units constructed in Belo Horizonte, from the 1990s, when urban policy became municipalized in the main cities of the country will be analyzed. The process of post- occupancy in 22 housing units and the housing policy guidelines over this period will also be examined.

In accordance with the municipalisation of housing policy, several guidelines for social housing were established, these being designed to meet immediate local need. For the construction of new housing estates which followed the general concepts of housing policies in the municipalisation process, the plan to build small estates, whose population would readily assimilate to the proximity and relationship with the city, was ratified. These housing estates were constructed in the urban areas available, originating in greater part from speculative retention. Thus, the cost of infrastructure and facilities could be reduced and future users could be provided with additional benefits regarding access to municipal goods (Teixeira, 2004).

At the same time, the programs originating from urban policy were distributed and applied in the municipalities in an attempt to meet housing demand. It is clear that local specificities demanded immediate action of a local nature, however, in practice the standards established by the federal authorities were maintained.

In Belo Horizonte the situation was no different. With the foundation of the City's Urbanization Agency (Urbel), in the early 1990s, the first estates were built in already urbanized areas, provided with nearby infrastructure and facilities and were composed of few units, in accordance with the characteristics of the available land.

As such land within the urban area was being occupied, it was necessary to seek less expensive areas near the outskirts of the city which made the implementation of the project feasible. Many of these plots had irregular topography thus compromising the construction of the blocks, the internal accessibility, permeability and pedestrian flows. As a consequence, the projects were marked by emerging disparities, particularly in relation to the external free spaces, and these form the primary focus of analysis in this work.

Currently, the demand for new housing projects in the city is great. The population of Belo Horizonte stands at 2,375,151 inhabitants (IBGE, 2010) and has increased 6.1% in ten years. Moreover, the housing deficit increased from 57,288 to 78,241 households, increasing by 36.7% over the same period (FJP, 2012). It is therefore of paramount importance that improvements in the construction of housing for the city's low-income population are sought.

Free spaces in housing estates

The research identified 22 (twenty two) housing estates, designed for low-income families and constructed by the Municipality of Belo Horizonte, under the auspices of Urbel, in the period 1996-2010. For analysis, estates accommodating a minimum of one hundred families were chosen since the relationships between free and constructed areas were deemed more tangible.

As the free areas of these estates were extensive, it became necessary to evaluate the transformation conditions resulting from their use (or not), from the design project up to ownership by the residents.

In general terms, Nogueira and Righi (2003) highlight the fact that free spaces in housing estates have often not received the attention they deserve having been misguidedly treated and appropriated as residues, rather than being designed as, places of social interaction, physical exercise, forums for the exchange of opinions and differences, rest and leisure. Such spaces need to be treated as areas where life takes place, and in which, the contribution of landscaping can provide enhancements to this particular environment.

Free spaces are of great importance in the design of housing estates and attend the specific needs appropriate for this environment and its inhabitants. The latter, especially children, need passive and active play areas which should be conducive to social interaction - an immediate benefit of good project implantation.

The design of the free areas in these estates, in the majority of cases, does not get to be executed. Existing vegetation is reminiscent of the original land, whilst amenities, which should provide a better quality of space and living conditions for residents, are improvised or not even constructed.

The lack of amenities in several of the analyzed estates can be offset by their proximity to urban facilities designed for collective use, which allow the practice of sport and more social interaction between residents: 3 (three) estates have no proximity with any municipal amenities for collective use; Three (3) are close to parks; Three (3) near plazas and thirteen (13) are near community football fields. However, despite their proximity with such municipal amenities, there is no original intention in the estates' architectural design to establish interaction or connection between them.

Within the estates studied, the wide differences between the free areas and those occupied by buildings are particularly noteworthy. The free spaces correspond to, on average, 75% of the total land area, in contrast to 25% built, as shown in Figure 1.

Although the estates have extensive free areas, they are not always intended and designed for the collective use or social interaction of the residents. Seven estates have no free spaces for social interaction, and in fifteen of them, the average area devoted to these activities corresponds to only 3.65% of the total land area. The proportion of open space used by the population is very small.

The estates' social amenities are composed of plazas, small squares, nurseries, small football fields or community centres. In most of them there is no maintenance.

The circulation of vehicles and pedestrians, which for the most part is facilitated by ramps and stairs, corresponds to 22.45% of the total land area. Parking areas make up, on average, 7.15% and the embankments, which are vegetated by grass, shrubs, trees or no vegetation, correspond to 41.75% of the total land area.

Figure 3. Fences and barbed wire - Coronel Jorge Dario housing estate Source: Authors' archive, 2013.

The architectural project adopted and the high gradient of the land on which the blocks were constructed are two common features of most estates. They are, furthermore, important factors for the type of configuration the free spaces follow.

All architectural projects are standardized and have no relationship with the site on which they are constructed. Blocks are pre-designed, four-floor, "H" or "I" format, arranged and adjusted on the ground in order to obtain the maximum number of housing units. On average, there are 188 housing units and 12 blocks per estate. The estates are surrounded by a combination of bars, walls, and barbed wire which impairs visual permeability and integration with the rest the city.

Figure 5. Implantation of AR03 housing estate generating embankments, supporting walls and residual spaces. Source: Author's Archive, 2013.

All estates were constructed on land with high or average gradients, which led to adaptations of the terrain such as embankments, retaining/supporting walls and even residual spaces. These are the same elements which therefore form the majority of open spaces and impede and hinder appropriation by the residents. Moreover, collective and social spaces are neglected both in

architectural projects and their execution and landscaping is not even considered in the construction of the estates.

Appropriation and transformation

As the projected space is appropriated by the residents, new interventions occur in the territorial configuration, reflecting the way of life of these people. Naturally, to represent their physical and social characteristics, new manifestations of appropriation are being constructed by the residents which portray the changes made to the original design.

Palhares (2001) clearly recognizes this fact and adds that the act of modifying living space can be understood as an intrinsic characteristic of human nature and the alterations, although de-characterising the formal and spatial architecture, allow residents the freedom to construct, "improvements in the quality of life" (Palhares, 2001, p.74).

The appropriation of free spaces is favoured due to several characteristics such as the elements of nature, the diversity of these elements, the form in which they are deposited, the interaction between the natural and the exterior, and the way that the affirmation of identity happens within this space. Coelho (2013) lists three reasons for the appropriation of free spaces:

1. Environmental - where integrated and contiguous green areas provide environmental suitability.
2. Functional - characterized by improvements in privacy and spatial demarcation.
3. Effective - consists of the development of psychological, emotional and sensory influences able to relieve states of depression and stress - creating spaces that can potentially generate the peace and satisfaction of the user.

The transformation of open spaces is encouraged by the segregation of urban space and by the construction of large spaces in the urban environment, as noted by Aragon (2006). Caldeira (2000) observed, when speaking about housing estates, that transformation occurs commencing with given spatial configurations and their instruments and this makes us value the importance of the project and take due care over its execution.

Therefore, one of the main reasons for the changes arising from appropriation is due to the shortcomings of the project. Ferreira (2012) adds that the socio-spatial, environmental and topographic conditions are rarely considered in the design of housing estates and this generates larger transformations in collective spaces starting with appropriation by the users.

However, Ornstein (1991) states that the inadequacy or viability of the appropriation of open spaces in housing estates revolves around three factors: legal regularization, the project and the management. Legal regularization consists of granting ownership rights to the residents, which is not always effective in reality. The project, for its part, encompasses how the blocks are arranged on the land and the way these buildings relate to free spaces. In most cases, this integration is neglected and seldom regarded by architects and public authorities. Management, in turn, constitutes the presence or not of a residents association/condominium and is related to how the residents organize maintenance, safety and cleaning of the buildings and common areas. This participation in the maintenance process makes clear the involvement and social relations between residents.

In the post-occupation process, ownership of the open space within the housing estates does not always correspond to that specified in the original design. In contrast to that idealized on the drawing board, amenities, when implanted, are used inappropriately or even destroyed. The maintenance of green areas is not carried out effectively - the vegetation is poorly maintained in most cases, resulting in neglected environments and ones that are poorly integrated into the landscape. Consequently, residents isolate the interior of their homes rather than engaging with the estate.

As to the form of free space ownership in the estates studied, we observed that residents carry out various activities: in every 22 (twenty two) estates, children play and people converse; In 11 (eleven) of these the residents have barbeques, wash cars and leave clothes out to dry; In 4

(four), residents have periodic parties. These activities are not always carried out in places designed or intended specifically for the purpose - one clearly sees a demand for spaces designated for children's use.

The main transformations resulting from post-occupation are the erection of isolating railings or walls between blocks; the transformation of some gradients into retaining walls; the privatization of parking places that are surrounded and covered and the appropriation of spaces adjacent to some of the blocks by ground floor residents. These are sometimes locked off and often have improvised openings and unauthorised new access to public roads.

Figure 8. Privatisation of free space for parking CDI Jatobá housing estate. Source: Author's Archive 2013.

Figure 9. Privatisation of free space by residents on the ground floor - Jardim Leblon housing estate. Source: Author's Archive 2013.

In addition to these observations there has been an increase in residents requesting Urbel to individualize blocks, expand the parking area, improve accessibility, expand access and even remove social and leisure facilities in isolated areas within the estates. Residents consider that these spaces encourage a concentration of people involved in inappropriate activities such as prostitution or drug use. Such demands have been reflected in the design of the most recent projects.

It is also possible to observe a trend towards the privatization of blocks, reduction in common recreational areas, expansion of parking spaces and incorporation of these areas at the rear of buildings, rather than in front .

Management and Maintenance

The management, which is one of the factors highlighted by Ornstein (1991) for the inadequacy or viability of the appropriation of open spaces, was also observed in the estates studied. In the cases analyzed, the management of each of the estates is undertaken by a general trustee/caretaker, who is responsible for all blocks and / or an individual caretaker responsible for each block. Thus eighteen (18) estates were investigated, while in 4 (four) of these, precise information was not forthcoming. In the eighteen (18) analyzed the situation is as follows.

Table 1. Management of estates : general caretaker v individual block caretaker

Is there a general caretaker?	Is there a caretaker in every block?	Total of estates
Yes	Yes	8
Yes	No	2
No	Yes	7
No	No	1

Source: the authors, 2014.

In seven (7) estates, management is undertaken by caretakers responsible for each block which confirms the desire to privatize open spaces - isolating blocks by means of railings and fences, as mentioned earlier (Table 1).

The maintenance of estates is undertaken, in the majority of cases, by the residents themselves as shown in Table 2 below. This reflects the financial situation of residents who are generally low income and who, by self-maintaining the estate, may exempt themselves from service charges.

Table 2. Estate Maintenance

Activity	Who does it ?			
	The residents	The CONDOMÍNIO	EXTERNAL	Nobody does the maintenance
Gardening	On 14 estates	On 3 estates	-	On 5 estates
Cleaning	On 16 estates	On 4 estates	On 1 estate	-
Renovation	On 6 estates	On 6 estates	-	-

Source: the authors, 2014

The difficulty of managing and maintaining spaces for socializing and collective use, as well as, the grassed and landscaped areas, which in most cases are in a precarious condition, are worthy of attention. It may be further observed that the situation of free space in estates that have a general caretaker is generally better than those that do not, even with the deficiencies presented.

Final Considerations

The plots of land used for the construction of the estates under analysis are far from the centre but are located near commercial areas and services and have some nearby space for leisure activities, especially football fields.

The blocks were constructed on land with excessive gradients and are therefore less suitable for the realisation of the strict architectural typologies suggested. In fact, Urbel imposes the adoption of design and construction projects which require adjustments in the topography in the form of railings, stairs and ramps and which do not always manifest adequate landscaping and optimal conditions of accessibility.

A significant area devoted to open spaces within housing estates, representing more than half the total area of land in all estates studied, has no leisure facilities that can attend residents' needs, such as a plaza, internal square or playground. It is noteworthy that in some of the estates they are nonexistent.

Most free space is allocated to embankments and vegetated areas that are underutilized by residents because of the gradient. For the same reason, the circulation of vehicles and pedestrians also occupy a significant area of the project. Thus, the free space destined to be permanent and for collective use is reduced and little used for socializing by the residents.

The inadequacy of free space projects on estates, combined with the difficulty of estate management, generates transformations in these areas. In general, a trend to privatize the free areas which become separated by bars between the blocks and the demarcation and individualization of parking spaces was observed. The phenomenon is repeated in most estates at the solicitation of the residents who justify it by the need for greater security and privacy.

Although the area of open space on the estates analyzed is representative, this does not imply good environmental quality. A hierarchy between the constructed spaces for socializing or movement of vehicles and pedestrians has not been established - they are merely a consequence of the insertion of the blocks on the land. Moreover the socio-spatial, environmental and topographic conditions of the land on which the estates are constructed were not considered.

The individualization of blocks constitutes transformation that has its origins in the estate management. As most estates have a caretaker in each block, residents demand from Urbel the right to close each off their respective areas. Moreover, the constant conflicts among residents that are referred to the agency have induced new solutions for the implantation of separate blocks.

At the same time, because users do not have property ownership rights they have no sensation of being homeowners and take little involvement in the maintenance of the buildings - soliciting Urbel when renovation is necessary.

It was shown that after appropriation, the free spaces undergo significant transformation. These changes are the result of the social housing production process which involves: the selection of the land; the project conception; the execution of the works; the ownership and the maintenance of the estates.

The transformation of free space already manifests itself in the construction of the estates as the amenities projected are not executed under the justification that the costs would be too high. The most obvious changes are related to use, for example, eliminating playgrounds which represent one of the most important requirements of the local population. Improvised parking, invasion of collective areas or amenities has also been common, which in turn affects the landscape and the permeability of the land, as well as, limiting the possibility of residents living together harmoniously.

A curious fact with regard to parking is that space is located on the flattest part of the estate. Sometimes the movement of earth necessary was used to justify the high cost of construction to the detriment of collective amenities.

The transformation of the free space in the estates, due to the inadequacy of the project, can still be seen in the appropriation of the spaces for pedestrian circulation. There are cases where spaces are closed and others take over this function. An example of this is present in the San José estate which received a makeshift ladder so as to allow people to climb over the retaining wall installed and have access to the other side of the estate.

Finally, the free space in housing estates are residual areas, little utilised, often privatized in their form of appropriation and that generate needs, not only in terms of landscape, but mainly in the need for leisure and social areas, especially for children.

Although, on the one hand, housing policy tries to address the quantitative problem of municipal housing with the production of many housing units, on the other, the quality of housing, the inclusion of these houses in the municipal context and the concept of decent housing have remained only a desire in the projects and their respective execution.

Unsustainable empty by inadequate use of urban space

Monica de Carvalho

City Hall of University Federal do Rio de Janeiro - UFRJ

Email: mlcarvalho1959@gmail.com

Abstract. *Studies of the Middle Ages tells of deforestation, since man saw the forest as barbarism, and reduced as a benefit to civilization for crops and rearing of herds. (Dorst, 1973). But, also, there is evidence of respect and admiration for nature the forms of buildings, urban landscape, vegetation and agricultural production in other cultures, as the Incas. (Bingham, 1911). Different paradigms, who built the various stages of human civilizations, explain the current situation that leads many urban centers in a significant deficit in environmental sustainability, a lack of resources for planning the shape of the urban landscape. Urbanism is to provide sustainable built man in his habitat, with comfort and environmental infrastructure to supply water, food, shelter, heat and light. This proves that man is capable of transforming the natural environment without destroying their livelihood condition, because the planned space is the best solution in the growing demand for food, housing, jobs and mobility of families, congregations, markets and armies. Governments around the world create managements to ensure sustainable human life on the planet, with the maintenance of corporations and lucrative markets in the global system. But the vulnerability is evident in various forms, such as natural phenomena and accidents in built space with large numbers of human casualties and loss of economic output. Experts say that the planet is finite, and does not support the artificial transformations, by an infinite lifetime warranty and urban production on Earth.*

Key Words: urbanism, environment, landscaping, sustainability, urban mobility.

Introduction

This research work reflects on the functions and uses in urban areas of Brazil's capital, in particular the City of Rio de Janeiro, my hometown, which will host two major world events in the period 2014-2016. The City of Rio de Janeiro today prepares the landscape of urban space for events, and demands that uses and global functions are sufficiently sustainable in territoriality, and this is another example of the many unforeseen past 20 years, as in the event RIO - ECO 92 .

The event RIO - ECO 92, of world importance, brought discussions of environmental problems, consequence of urban growth on the planet, made a significant change in the planning of cities thinking about the degrading performance in the natural environment. So Rio de Janeiro, temporarily, was the capital of Brazil, declared the President Mr. Fernando Collor de Melo, and attracted representatives from 180 countries of the world to decide what steps to take to reduce environmental degradation and ensure the life of the human and other living beings. The central idea, left the meeting was to provide sustainable economic development with the consumerism of moderation to better ecological balance through preservation plans and environmental conservation. So, important documents were created as the Earth Charter, Biodiversity Convention, Desertification and Climate Change, the beginning of Forests, Environment and Development and Agenda 21. Agenda 21 has become the most important instrument to be followed for each country, each region and each city representing urban areas, and which produces the livelihood and are concentrated forms of growth and economic development of societies and peoples of the planet.

The City of Rio de Janeiro has a natural landscape with medium mountain ridges and are interspersed with its various neighborhoods and the limited road system and the sea. However the challenge is to get world events, resolving review their sustainable intentions revealed at the

time as a condition to grow the economy and the population of the city, and the natural environment as its main axis. With concepts of Agenda 21, the Rio Declaration (Earth Charter) and the Conventions signed in the RIO-92, the city administration moves efforts to create actions and targets the improvement of urban conditions for sustainable development and that the main focus are: Social and Economic Dimensions, Conservation and Management of Resources for Development, Strengthening the role of the main social groups and Means of Implementation.

Then, with bases in this brief exposure, this research is to know the "State of the Art" and the reflections on the issues that are compelling and disturbing to shape the urban form of the city that, after more than 20 years, is again interrupted in your routine and submit to the urban trials, which makes seeing possible horizons in the common future of cities elected to major world events.

Aspects and impacts in the urban landscape

Middle age studies speak of deforestation, since man understood the forest as barbarism, and reduced as a benefit to civilization for crops and cattle breeding (Dorst, 1973). But, also, there is evidence of respect and admiration for nature in various forms of buildings, urban landscape, vegetation and agricultural production in other cultures, as in the Incas. (Bingham, 1911). History shows the different paradigms, who built the various stages of human civilizations and explain the current situation that influences many urban centers to a significant deficit of environmental sustainability, a lack of resources and planning to reshape the urban landscape. In the collective perception urban landscape expresses how the individual must read and understand the city and it can move to the most possible activities related to who elect the urban site as the ground of its existence.

In the years 50, 60 and 70 the Town Planning intensifies and is providing sustained man in his habitat built with environmental comfort and infrastructure for water supply, food, shelter, heat and light. This proves that man is capable of transforming the natural environment without destroying its condition of living, because the planned space is the best solution in the growing demand for food, housing, jobs and mobility of families, congregations, markets and armies. As a result, governments around the world create steps to ensure sustainable human life on the planet, with the maintenance of corporations and lucrative markets in the global system. But one notes the vulnerability in several ways, such as natural phenomena and accidents in built space with large numbers of human casualties and loss of economic output. Experts say that the planet is finite, and does not support artificial changes to an infinite lifetime warranty and for sustainable urban production on Earth.

The United Nations Conference held in Stockholm in 1972 happens with the purpose of reviewing the synergies between the Environment and Urban Development, establishing new visions and urgent procedures for the greatest possible viability to sustain the future of cities across the world. So are magnified concerns, reviews, commitments and measures to create new uses and functions to the best of urban city and rural areas. The situation called for attention in all the processes governing the productions which support the cities, as the latest models of social and productive organizations are established in urban city to keep workers in at least 50% of the world's population, but 1/3 that live in sub-human conditions known as favelas.

In Rio de Janeiro City this proportion is confirmed and becomes the most difficult task to compose the form of the urban landscape associated with a sustainable condition for economic production and environmental preservation of the city's future. This view is undeniable to common eyes, it creates an impossible density to be recorded in real time, and does not allow the actual location of shifts that move the socio-economic production, which is the thermometer to provide the conditions for development with urban sustainability and environmental.

Other aspects are shown in the city of Rio de Janeiro as relevant which are the administrative expenditures with urban violence and the production of solid waste, which saturate the existing

sectoral structures in the Municipal Administration, creating impacts of disproportionate dimensions on the challenges signed with the remainder the planet, and being in sight the approach of the 2014 and 2016 world events for the World Football Cup and the Olympic World Games.

About the spaces devoted to the world events, there is nothing to disagree about their real possibilities of being available. However, the same result does not occur on the perception on urban routines that promote socio-economic production of day-to-day city, and they need that their movements are carried out on roads and land transportation systems, today already seriously committed to the fluidity by several reasons the urban phenomenon.

The municipal administration made a bold plan born in 2010, which provides a radical urban operation that transforms urban axes, transport types, routes and systems that served the city for over 40 years. See what happened with the complete demolition of the high Perimeter, which bordered the entire port area of the city, which created a ring road to meet the arterial routes of inputs and outputs regional and international airport of the city.

Many impacts already become visible at a future understanding of the shape of the city, when it has the waterproofing without provision of intense forestation and landscaping in new urban axes, in addition to condition the intensive use of public transport systems of long distances (BRT and BRS), which were preferred to place surface or underground rails, and the creation of new shopping centers, technological and industrial poles, and as creators of intense shifts the provision of services, labor, work and jobs, mainly by harmful production of polluting waste.

Although not seem unheard and not disturbing, but these mentioned factors indicate the extensive spreading condition of the city, as the transfer and upgrading of subnormal agglomerates or slums are located mainly in the central areas of large real estate appreciation of the city, gathering around the least 2 million people a housing shortage in the city of 200,000 units, and only 60,000 units were contracted to build the last 2 years. The transfer and the readjustment of each cluster means a problem for many residents, which represents the change in the commitment of families with their urban living needs with their attributes related to labor, employment, health, education, transport and leisure. And change often cannot be gradual, given the condition of tight deadlines to have the new morphology imposed in the city that will receive two world events in a short time of two years.

The spreading of the carioca metropolis promotes many social, economic and environmental delays, since the productive urban axes of significant scale will be transferred, considering the limited road and inefficient road transport systems, sanitary and storm sewer system inadequate and outdated and the constraints physical-geographic of a city choked between the sea and the mountain ridges. The city of Rio de Janeiro today, still sheltered themselves from the omens that threaten their preservation and conservation signed in commitment to the Earth Charter and Agenda 21 for the global environmental event RIO-92. Therefore it is visible from the appearance and impact refers to the new solid waste, where landfill space no longer meet the demand, as well as new areas for this purpose, since they do not become possible to offer the metropolitan area of the city thus saturating the security of the neighboring municipalities, still very poor and latent in his urban and socio-productive structures.

Given the above, the City's commitment to the Rio de Janeiro, to meet the requirements of providing world events, has become a task of great responsibility in the present and in the future in order to get the city morphology with guarantee of intelligent conditions for effective and sustainable metropolis over the next 30 years. This time leading up to the global meltdown which provides urban life occupy 70% of the environmental resources of the planet. That future should ensure the promise that the Urban Contemporary 50s did, after Chicago and Bauhaus School, when allowed ratify on ensuring the comfort in the urban condition at the expense of rural condition, the full and stable permanence of man due the relationship of economic output with the accumulation and capital surpluses.

The morphology of unsustainable empty

Although the experience of Rio de Janeiro City is not as exceptional as the transfer or displacement of socio-productive routes, this comes at a time of various changes imposed by both an internal and external demand, promoting conflicts and even aggravating that can make it impossible many plans and projects still under development and already running. In theory, the change shaft through urban operations produces significant results, often unforeseen or foreseen, it may be aborted by an external demand, creating action of irreversible stages, for example, the formation of voids that may become urban areas unsustainable, both the social focus as economic and environmental.

But what can be said of unsustainable empty? Well, then, urban voids are disturbing themes and replicating over the past 50 years in almost every city in the world. The Modern Urbanism developed solutions and also problems throughout his 60 years in office, and inspired controversial authors like: Ebenezer Howard as the defender of the garden city with 30.000 inhabitants surrounded with green belt; Le Corbusier as a defender of super vertical city hostels towers on stilts holding free and green land for the passage of people and vehicles; Daniel Burnham as a defender of the city as the backdrop for artistic monuments in green parks. And otherwise, the Jane Jacobs author, questioned these monotonous approaches of Modern Urbanism, accusing the main reason of abandonment and death of cities.

But today, the theme of the life and death of cities (Jacobs, 1961) could not be supported on this issue, given the new grounds of the city that need to raise over environmental preservation and the restructuring of production, with the focus of globalization world economy. In this vision, new paradigms and institutionalities are thought to promote change with adjustments or changes, on expected the supposed urban voids, such as remnants of the spaces of the large factories, and other models of urban occupation.

In the city of Rio de Janeiro Urban Plan, with some delay this temporality, preferred the view of environmental reserves as the Barra da Tijuca Pilot Plan and Baixadas of Jacarepagua, Sepetiba and Guaratiba, including Vargens, beyond the Fundão Island - City university, and other districts of the Baixada Fluminense. These spaces, today, are seen as non-functional urban voids for socio-economic production of the city. Then the thought and Janes Jacobs vision are present, and follow fostering municipal administrations, on the emergence of creating strategies to move new "inputs" in the city of global dream. And so perhaps the managers of Rio de Janeiro City chose to get involved, based on the question indicated by Jacobs, leading the city to apply to world events, with the intention of renewal and recovery of empty spaces, considered lacking in production and inhabitants.

But even on the basis of thought and Jacobs's view, the City of Rio de Janeiro develops practices that have not and are not educated on the issue raised by the author. Curious fact about the inclusion of consortium operations in the area of Porto Wonder, the new urban function of Fundão Island and the other inserts of road systems and transportation, that enter areas previously considered of environmental reserves of the city, as the Vargens, Baixada de Jacarepagua, Baixada Fluminense, and Restingas Guaratiba and Sepetiba. Thus, the city will be relocating and moving away from the urban area of the city, without the minimum infrastructure such as sanitation, sewage collection and disposal of solid waste and other urban facilities such as health centers and schools. The order is now being functional, no longer be the condition of conservation areas of environmental reserves, which once served the new world order from the RIO-92.

From then on, it creates a paradox that affects the urban organism, functioning as a city, as it is exposed to surgery with urban operations that break and exclude old urban infrastructure such as bridges, overpasses and elevated. Now, since no real vision of its derivatives, and through their elimination or substitution by other equipment, considering many have not yet effective and sufficient for the flow and maintenance of various urban routines being productive or not, but routines that emerge from a city that even with empty, still remain with "green lungs".

In Modern Urbanism scheduled to be compartmentalized city plan with its uses and functions, and empty were filled with green parks and squares that served the leisure of residents. But Jacobs housed the concept that these green areas were empty, they were only accessible to residents, while on the rest of the residents moved to produce other extreme of the industrial city. Anyway, do not explain the green areas as environmental and ecosystem areas, and the time was trying to degrade them here in Rio de Janeiro, including the Tijuca Forest Park, Quinta da Boa Vista and now at the end and unfortunately, the Flamengo also already suffering from neglect and improper maintenance.

Green and environmental reserves - potential empty

In Rio de Janeiro City is confirmed, then a functional use of vision in areas of green reservation? This is only for fear the thought and vision of the death of the city? Or is it just a new urban-environmental vision? As support and how to present to the world a city of so many natural environments interspersed between seas and mountains, now, a vertical city in the entire region "Marvelous Port" and sprawling to the region of Vargens, the Baixada Fluminense and Jacarepaguá and, the Restingas Guaratiba and Sepetiba? What new urban concept can be allowed to present to the world the new candidate city to be global?

From this observation, this research work brings to the analysis, the effects that are repeated in the municipal administrations that follow in the city of Rio de Janeiro, primarily on the improper and inadequate practice of Landscape discipline with the lack of trees in compensation environmental urban zone. In theory, the urban landscape expresses how the individual must read and understand the city and it can move with comfort, for the most possible activities related to who elect the urban site as the ground of its existence.

But it is important to accept that arises every minute, and uncontrolled speed, new human needs that need immediate solutions, in order to give all humans on the planet, and in order to ensure the economic and financial corporations met their productions and of their profits. This turbulence produced in the last 60 years, excellent solutions and also created in the wrong lane, little effects or never perceived, that are present in incommensurable scales, such as the reactions of the atomic world and the bacteriological abysses, formed from effects of molecular transgeniases.

The human being is faced with today, with something almost unrecognizable to himself, or something that inspires you to go further, and provide himself with a sensitive intelligence and great wisdom. So, putting it to the service itself, putting to the service of all who provided an entity transformer, and the entire environment that surrounds it, observing and following the signs, which should guarantee the required compensation for sustainability the interactions of the natural environment to the built environment.

Research on the best actions to be recommended and implemented in future urban administrations, and these can develop the best return for the sustainable use of the city and can restore the gaps that form the voids in these landscapes. Instead, these can work plans and pilot projects for the restructuring of green empty and recovery sites containing species which may have been extinct from the original habitat, transforming them into areas of Urban Tourism and Environmental Alternative or Urban Development Centers as occurs in the incipient Vilas Green being tested in mountainous regions of neighboring towns.

Therefore, the recommendations and guidelines developed in other urban centers outside of Rio de Janeiro, and foreign cities recommend that urban spaces are inventoried in order to make qualitative and quantitative data of vegetation to provide its Environmental Landscape Plan. This, so that the city can have real and substantiated data, in order to review problems and solutions for environmental sustainability. This is reasonable as it has knowledge that the Landscaping is a reason practiced since the Middle Ages, and in Europe the initial movements of the urban landscape planning occur in half of the fifteenth century and the appearance of landscaped public spaces occurred in the century XVII. (Segawa, 1996)

The spaces of landscaping and urban forestry

The practice of Landscape contributes a lot to keep the moisture in the air and to the permeability of soils, which softens in the flooding of large cities. This interferes with quality of life by visual benefits, and behavioral, in addition to landscaping come to enhance the preservation instinct that arises in the consciousness of people who want to have more green space from the streets, sidewalks even in their own homes and workplaces (Bernatziky, 1980).

The fact is that the landscaping adds the development of a variety of species of plants native or not, and that with this development allows other living beings such as insects, birds and many other animals can stay longer present. Thus, get your food next to residential gardens, green parks, malls and other habitats that may encourage the approach of flora and fauna biodiversity, which are by nature an intelligent, self-regulating environments and therefore sustainable. For example, we have bees that feed on nectar from flowers, birds also carry seeds and other ecosystem interactions that come together for an infinite improvement of biodiversity. (Chacel, 2000).

Urban centers, according to international survey conducted in 1988, already home to more than 40% of the population tends to increase observing comfort of life proven in more developed countries. So being generated environmental impact by expanding cities, is studied and applied in various locations in the world plans to landscaping and urban forestry. Different authors have already advocate the practice and highlight importance of their implementation and maintenance, such as comfort for the city, air purification, thermal balance, noise reduction, financial and landscape qualification of a property, attraction of wild fauna and flora, options leisure and rest for the population and development of the historical-cultural and environmental tourism (Ruschel and Carvalho Leite, 2002).

In Brazil, influenced by Europe, cultivated public gardens arise only in the late eighteenth century, with the aim of preservation, sanitation and maintenance of species. D. Pedro II valued by a preservation order of the natural environment, which promotes our first environmental legislation. However, the periods governed by regimes of the Empire and the Colony in Brazil have important records in relation to the environment (Earth, 2000). But the treatment given to the elements was mercantile character. That is, nature was seen as a commodity, under the influence of anthropocentric doctrine - in which man is seen as the center of all things. (Abreu, 1997). But, there is also the strong influence of landscaping on urban design, which elucidates the time the trees and plant elements are to be understood as structuring elements of urban space, and have the force of such acquired form, which shall be define new types and styles of landscape and urban design. (Farah, 1999).

However, professional landscaping in southern Brazil, city dwellers as Maringa, Piracicaba and Ribeirão Preto have published many articles and symposia to promote the best possible dissemination of the importance of the exercise of discipline applied to the infrastructure of cities and state capitals, with the rational use of urban forestry. Explain that part of the ecosystem of trees plays a big role, influencing the weather conditions, air quality, soil fertility, in the life of animals and plants. In the big cities, which are the most responsible for CO2 emissions, planting trees comes assist in the purification of the whole environmental system.

Studies indicate that some species should be preferred as the Jatoba, Rosewood, guapuruvu among others, which are species of great absorption of carbon dioxide, which both overloads global warming. Simply not only that but also explained that a single change adult has the ability to spray around it about 500 liters of water / day, which makes the air and much more fresh and pleasant environments. For this reason, a woody place comes to have a difference of 10 degrees less than the temperature measured in areas without vegetation (Chacel, 2000).

Topics for this analytical study are being conducted primarily in smaller cities or prefectures in growth, as those located in the southern and midwestern Brazil, and these working groups estimate that the landscape study and practice acts as update tool of urban functions, as well as a

new condition to effect the purposes of socioeconomic and environmental sustainability in urban centers.

The experience of the city of Ribeirão Preto - SP

Former Superintendent of Landscape and Environment of Ribeirão Preto City Hall - SP was responsible for the implementation of a program which is shown below with the title *Landscape and Urban Centralities* by Sergio Marin de Oliveira" between the years 2001 and 2004. "Program Objectives: i) signic relevance; ii) expansion draining areas; iii) reduction of heat islands; iv) biodiversity enrichment. We believe that today's cities, with their enormous needs of all types (health, education, transport) can't, in spite of these, and do without neglecting, as a paradigm of systematic reconstruction, for environmental and landscape issue. The landscape design in its range of intervention, should not be a possibility (the result of indifference, ignorance or weakness of funds), but a vital necessity for the future of cities, as worthy of living place, living and working as a place of citizenship, democratized and qualified public spaces. "

The own spaces for urban vegetation

Similar afforestation view in public and private open spaces, trees accompanying the road system exert ecological function, in order to improve the urban environment, and aesthetics, in the sense of public roads beautification and consequently the city. And as afforestation accompanying the road system is its subservience as an ecological way, linking the free vegetated areas of the city, such as squares and parks. In addition, on many occasions, the tree in front of the house gives this a particular identity and provides direct contact of residents with significant natural element, considering all its benefits. (Concise Oxford, 1988)

However, many problems are caused in the confrontation of unsuitable trees, on the urban equipment such as electrical wiring, pipes, gutters, sidewalks, walls, lampposts, etc. These problems are very common viewing and cause, in most cases, inadequate management and damaging the trees. (Velasco, 2003). It is common to see trees pruned drastically and many phytosanitary problems such as the presence of termites, drills, other types of pathogens, physical injuries as barking, hollow and rotten stems, chipped branches, etc. (Velasco, 2003)

Noting this common situation in Brazilian cities, adds to the fact that the shortage of trees along the streets and avenues. In this sense, it is essential we consider the need for constant and proper management aimed specifically at the urban trees. This management involves concurrent phases of planting, driving the seedlings, pruning and necessary extractions.

To implement a municipal system that accounts for all this demand services, it is necessary to consider the need for a specific municipal laws, administrative measures aimed to structure the relevant sector to perform the work, considering fundamentally skilled labor and appropriate equipment, as well as involvement with companies to help financially support projects and idealized actions, and with the general population. The latter may happen, preferably through environmental education programs for the theme, seeking to involve in fact the residents in afforestation or reforestation process of the city. (Houass, 1988)

Importance of creating green space in urban reserves

As for the microclimate

In the case of the urban environment, it appears that the rapid population growth in conjunction with other variables of the urban space, contribute significantly on changes in climatic elements. The city causes changes in the surface parameters and the atmosphere, which in turn lead to a change in energy balance (Lombardo, 1990).

According to Furtado and Melo Filho (1999), all landscape elements must be carefully handled in order to bring benefits that will interfere in the integrated project, aimed at improving air quality, the shading of the building and surrounding areas, the ventilation control and moisture. Most of the heat load of a building comes from solar radiation and the outside air temperature, a strict control of the microclimate elements being necessary to remove an excess of energy that would make the built environment inhospitable.

According to Lima (1993), urban areas constitute an artificial environment, since they have high concentrations of paved area constructed and favoring the absorption of solar radiation during the day and the night reflection. Called heat island, this phenomenon can have a very significant thermal differential to more vegetated sites. The trees intersect, reflect, absorb and transmit solar radiation. Proper tree planting and good ventilation are two key elements for obtaining the thermal comfort for the humid tropical climate. The tree set placed at a more appropriate distance possible from the building provide a good shading in the risers of buildings, composing a more favorable environment (Furtado and Melo Filho, 1999).

As for health

The green area serves to constitute an area of "social and collective", is important for maintaining quality of life. For ease of access for all, regardless of social class, promotes integration among men (Martins Júnior, 1996). The OMS recommends that cities have at least 12 square meters of green area per inhabitant (Lang, 2000).

Trees can be considered antimicrobial agents. The trees still act against atmospheric pollution, noise and visual (Pedrosa, 1983).

In the urban environment, have considerable potential for removing particles and atmospheric greenhouse gases. Curtains experimental plants were able to decrease by 10% the dust content of the air (Pedrosa, 1983). Excessive urban sound from traffic, equipment, and construction industries interfere with communication, leisure and people can rest psychologically affect them or physiologically. You can make use of trees as a complement to the alleviation of the noise, since the vegetables reduce the reverberation of sound. It is necessary to emphasize that the protective effect varies with the frequency of sounds, with the position of the trees in relation to the emission source and the structure and planting composition (Milano, 1987).

According to Bianchi (1989), the trees also helps to mitigate the visual pollution, because the trees are components that give shape to urban environments and playing a major role, defining spaces, featuring landscapes, visually guiding and enhancing properties, in addition to integrating various components system.

As for urban ecosystems

The standardization of vegetation in urban centers is one of the greatest dangers to the earth's ecological balance and should be avoided. The diversity of plant species is a basic condition for the survival of animals and the ecological balance.

Cities that do not diversify its vegetation may turn into green deserts. Each city should give higher priority on native species. When this happens, the tourists will be happy to visit them, as they present distinct and typical aspects of its vegetation.

The current legislation

According to the Federal Constitution, every city with more than 20,000 inhabitants must necessarily have a master plan approved by the City Council. So, will the existence of urban zoning identifying sectors with vocations, destinations and specific occupation rules. The zoning determine the specific occupation rules which, in turn, generate facilities and / or difficulties for the existence of urban forestry.

The creation of public squares and parks requires for its effectiveness, and legal foundation and economic resources, the availability of physical spaces. The zoning laws and subdivisions to define rules and installment conditions, destination and urban land occupation can guarantee these spaces, forming highly effective instruments for the realization of a suitable tree planting system.

The laws that determine and govern the areas of permanent preservation and immune native tree species are cut to Federal Law No. 4771 of September 15, 1965 - Forest Code and the State Law No. 8518 of January 21, 1992 - State Forest Code.

In this set, the municipality must have a specific legislation. In order to help municipalities, as the example of RGE - Rio Grande Energia, responsible for distribution of electricity in the southern region of Brazil, who made a collection of laws and environmental projects that can guide in defining the best legal guidelines for implementation of an environmental management policy.

Conclusion

The knowledge and scientific research as the basis for the management of green areas would be the foundation that would support the control and management of these areas. According to chapter 35 of Agenda 21, it is emphasized the role of science for sustainable development where scientific knowledge provides support for the prudent management of the environment, ensuring the daily survival and future development of humanity. You can't control or manage the plants and animals of urban green areas without knowing the biology of the species, the relationship between them and the relationship with the other components of ecosystems.

In the face of threats of irreversible environmental damage, lack of scientific knowledge can't be an excuse for postponing measures to protect the environment. In a broader and more general analysis it appears that the lack of knowledge often is usual to assume that protecting the vegetation is protecting all living beings who live there all your life or at least part of it. This is the possible position with the available knowledge, but it does not guarantee the success of the control and management of green areas. With the evolution of knowledge will be allowed a more secure control with scientific bases and more adequate monitoring.

In this new section appears on the priority guided models of cities that make studies, projects and the implementation of programs, they always monitored and rectified by Technical and Scientific Committees designed by international rites of ideal functionality that will promote the city that reacts technically front of own adversity. So it's definitely inserted in this context, the construction of a vision with mature approach for providing scientific disciplines multidisciplinary tone in order to create new demands on organizational chains of public and private companies, but also creating necessarily the true condition of participation public and citizen in the various aspects of sustainable development of urban life in cities. Thus arises the strong condition of raising cultural efforts in order to create the new 21st century citizen profile, providing for the training from basic school cycle in the course in Environmental Education for Citizenship.

The matters set of Urban Environmental Planning intended to show how isolated and fragmented attitudes of the government, whether in the physical space, either from a legal point of view, is a vision of unilateral interests, are able to create situations of economic and social spending, generating conflicts and social dispersion. Should be alert authorities that the occupation, both spontaneous and formal, reserve areas has caused many environmental damage from landfills, stream channeling, street opening and construction of condominiums in permanent preservation area.

This research has also demonstrate the impertinence of expropriation made by the Government of private reserve areas, whether in environmental issues presented, either because the installment law of urban land make possible an active joint government with the landowners, provided they are used democratic actions and the government there is indeed in the interest of minimizing costs and build consensus. You can still submit proposals open to resolve the impasse caused by the expropriation and for a possible discussion of an Urban Design for Environmental Parks and corrective measures in the medium and long term so that the competent authorities pay attention for environmental issues.

Thus, there is sure to have achieved contribute to the deepening of issues relevant to the understanding of the issues presented and that this work can indeed be a tool to elucidate polemics, enable the defense of the collective interest. With the facts and analysis presented here, there is sure to have fulfilled the duty of citizens and technical research, understanding that failure to not investigate and denounce means complicity.

Interactions between agricultural-systems and urban forms in Sardinian villages

Adriano Dessì

DICAAR, University of Cagliari, Italy. E-mail: adrianodessi@libero.it

Abstract. *The rural landscape is historically based on mutual interaction between the *bid̃da* and *sartu*, the village (*villa*) and the countryside (*saltus*). The forms of the Sardinian countryside, the openfield in the plains and hills with cereal crops, the closures in the inland basalt slopes and highlands used for sheep grazing, are deeply connected with the form and structure of minor towns. The contribution focuses on the historical reasons and the contemporary developments of three specific relationships between Sardinian villages and their agricultural systems: (i) Villages situated in the plains are placed in a central position in relation to the openfield and they are characterized by strictly closed blocks which have large interstitial inner spaces between them, that constitute the sites of accumulation and primary processing of cereal resources; (ii) "Margin" villages between environmental and agricultural specialized systems, or between different agricultural systems, show mixed structures and forms that are generally compact and adherent to the topography. The fringes of these centres are highly dependent on soil conditions, on crop specializations and different topographical forms. The porous space of the block gives greater precedence to the peri-urban *hortus conclusus*; (iii) The pastoral villages of the great *tancas* (enclosures) are composed of narrow elongated "spindle" blocks located on the terraces of the inland hills. The adjacent agricultural systems are a few kilometres away, in a pattern of total autonomy and division among the cultivated fields and urban forms. The contribution aims to focus on the effects that these historical relations have today on the creation of new forms of contemporary habitat.*

Key Words: rural landscape, villages, urban forms, agricultural systems, enclosures

The exceptional poverty of the soil combined with his incredible fragmentation of ownership and with an economy fundamentally based on sheep farming, paradoxically, have given an exceptional diversity of forms to the Sardinian landscape: we can find in just over 20000 km² many of the structures that characterize the rural 'ancient continent from the closed pastoral of the most distant parts of Wales to the openfield landscape of Lanières in Alsace, peri-urban regions of orchards of Andalusia on the Iberian Peninsula.

This extraordinary material and cultural palimpsest, consisting of the rhythmic succession of the *bid̃da-sartu* binomial, villages and agricultural systems domain, or consisting of the different agro systems, is the ability of the Sardinian landscape to change "in short," and to conform and adapt human habitat to a severe and arid soil and also be structured around complex social rules, extreme collectivization of resources or drastic ownership manifestation, in a continuum made up of rural fragments of floating islands, of landscape "plaques".

The research interest on the landscape, or rather, on the rural landscapes in Sardinia, then, is based on this ability to be revealing of urban forms that for a long time, it represented a direct extension or densification of them, in this so interpenetrating and structured two-way relationship, that we can consider agro systems and villages as a supportive and cooperative aggregation, two entirely consistent expressions of architecture of soil. The origin of the Sardinian village, despite the numerous classifications and structural analysis, it is nevertheless difficult to understand, and indeed, for a long time, it had "the disconcerting habit of disappearing, reappearing, disintegrating, fractionating, recomposing in compact clusters, even the habit of changing location (...)."¹⁸²

¹⁸² John Day, *Villaggi abbandonati in Sardegna dal trecento al settecento*, ed. CNRS, Paris, 1973.

And however, a constant in its geographical location is precisely this founding relationship with its more closely agricultural domains, which only for convenience of description, can be described as anything else from the same village, even when there is no physical continuity between the two systems. The house and the field, in fact, can be defined as two complementary devices of production and organization of agricultural resources and, in accordance to this, conform the soil and are in turn modeled.

It exists in Sardinia, and then remains very strong, that extraordinary identification between urban and territorial "individual", based on their agro-pastoral culture and the everyday construction of rural landscape that even in inevitable contemporary transformations, it is still rooted and often contrasts the inappropriate use of territory.

Figure 1. Ground uses and organization of the village territory.

The Mediterranean landscape: a history of agro-urban relationship

The rural history of Sardinia is not very different from that which characterizes the Mediterranean landscape: the continuous layering of cultures, diversity of land uses, the different urban morphologies, make the island one of the places in which the continental rural forms have specific configurations. In particular, the structural and perceptual contrast between the specialized cultivation encloses and of pastures and upland expanses of open fields of cereal crops or extensive contemporary, the Sardinian landscape enroll in the formal evolution of rural Mediterranean and therefore also in its constant mutation processes.

However Sardinia still shows those "figures" and "geometries" imprinted by strong colonizing cultures, such as the Roman one (for example, is still significantly visible in the so-called "valley of Quartu", the hilly hinterland of Cagliari) or the Arabic one, especially in the management of water systems and peri-urban agriculture of small villages. The same "*domus-structure*" of the agricultural villages of Sardinia, it appears that expression of Roman *rus in urbe* which sees in the rural landscape the exact morphological and economic origin of the more rooted urban fabrics.

In the whole area of influence of Andalusia, the Iberian peninsula and Mediterranean France, the *huertas* accompanied and structured the development of the cities which, albeit with a progressive consumption of soil, embraced them within their confines and guaranteed their historic function. In fact, these spaces, as well as influencing urban growth, were considered valuable for the complex infrastructure of the cities themselves, especially in relation to the articulation and distribution of water resources, whose network often designed and organized - as happened with the Romans - the urban fabric, making it morphologically continuous and unified with the countryside.

The minimum, suburban rural lots, in such contexts, gradually merged with the large residential blocks of the city, describing them as large open interior space, or large, productive estate farms.

Rus in urbe - the countryside into the city, but also the city into the countryside - is the first real expression of that structural union between urban and rural that makes Roman society the first real landscaping society in history: "within the peaceful and lasting context of the Roman Empire, rational design flows back from the cities to the territory, and puts into the landscape the regular forms of agricultural subdivisions, roads, bridges, aqueducts, border lines, canals and ports: a functional support and omnipresent image of a homogeneous civilization spread over a very large geographical area."¹⁸³

For a long time, even after the end of Rome, the strength of that urban and territorial settlement model was able to continue as an ordering platform and was effectively the landscape approval system on the continent, although in its various forms. A real "ground-city", a real "continuous monument" which, in many ways and in many cases, formed the solid basis even for the construction of contemporary landscapes.

The Mediterranean countryside, even subsequently, especially in its more urban spatial forms, the *enclosed garden*, the rural court, the suburban garden, was for a long time the area of man's production and socialization and made up for the well-known poverty of strictly urban public space. In the whole Mediterranean area, the historic links between the city and forms of agriculture that surround them and provide them with supplies, for a long time, represented a necessity and subsistence, but were also generators of alternative spaces to those *intra muros*.

Figure 2. The Ghardaia "cultivated fabric".

In the Arabic settlement fabric, the countryside was a source of income for the city (medina) in which the vegetable-garden spaces were already used for relaxation and leisure. In the coastal cities (Beirut, Tripoli) they were located within the walls and maintained through collective irrigation systems (dams or large tanks) or individual systems (wells, boreholes) and were located in the vicinity of the ports for marketing the produce. In Istanbul, the horticultural gardens are the Bostan, which face each side of the Bosphorus, whereas to the north of Tunis large orange groves (jnina) and olive groves have been preserved in the peripheral residential areas.

In the countryside of Tunisia (the rif), the well-off people stay in Swani, properties and rural homes; urban oases in Damascus (Waha) represented a gradual and hierarchical landscape that allowed the passage from city to horticultural gardens and orchards, to grasslands and cornfields, before finally reaching the wilderness. "

In the whole area of influence of Andalusia, the Iberian peninsula and Mediterranean France, the *huertas* accompanied and structured the development of the cities which, albeit with a progressive consumption of soil, embraced them within their confines and guaranteed their historic function. In fact, these spaces, as well as influencing urban growth, were considered valuable for the complex infrastructure of the cities themselves, especially in relation to the

¹⁸³ Vitta, M., *Il paesaggio, una storia tra natura e architettura*, Einaudi, 2005, Torino.

articulation and distribution of water resources, whose network often designed and organized - as happened with the Romans - the urban fabric, making it morphologically continuous and unified with the countryside. The minimum, suburban rural lots, in such contexts, gradually merged with the large residential blocks of the city, describing them as large open interior space, or large, productive estate farms. It is also the historical continuity between urban and rural areas that can be traced back to the ecological porosity and permeability of the Mediterranean urban fabrics. In fact, there exists a close relationship between the private and protected open space, whether it is urban space or cultivated fields, or also intimate space of domestic life and the closed structures of the Mediterranean peri-urban rural landscape.

It is no coincidence that the greek word *kepos* (the garden) and the Latin *Hortus*, in the *Middle Ages* have been treated with the Indo-Germanic word *ghordho*, which also indicated the court and the fence, reaffirming the closed, protected and circumscribed nature of the space, typical of a *hortus conclusus*. In addition to protection and control the enclosure guaranteed, biotopical balance and diversity of crops, but also spaces for socializing away from the hottest conditions. Even when in the post-medieval age -exactly as happened to the urban processes - the need to subdivide the lots according to the property divisions and the farming types and techniques led to a gradual densification of divisions and lots near the cities, re-proposing organizations, paths and structures quite similar to the urban ones, the autonomy of the two systems and the formal and functional integration between the city and the countryside were not lost. The outcome of this process in large parts of rural mainland, is therefore that of a subdivision in *Lanières* - long and narrow lots - a direct expression of this primordial urban occupation of the countryside.

The agrosystem-village relationship in different forms of rural landscape in Sardinia

Due to this strong link, the village and the agrosystem are arranged in the territory according to different and changing social, economic and nature of the land conditions.

However, the persistence of a dominant economy allows us to identify some repeated ways to organize the rural space and then to "give form" to a landscape so recognizable and prevalent. The fundamental relationship between agriculture and shepherding for centuries has affected the habitat of Sardinia. It is in this way that discriminates against some forms of housing permanent and immanent, from the most nomadic and ephemeral. In fact, it could be more synthetic if we say that the behavior and the work in the pastures determines the position, shape and durability of the Sardinian settlement. In Sardinia the transhumance, for example, is responsible not only more compact and fortified forms of mountain villages, but also more fluid and dynamic configurations of spread habitats in peripheral regions, of which it is the main and the relatively recent colonization reason.

The permeability of rural areas within the urban fabric of the village is measured in multiple scales. However, it is the nature and size of the public space that we have confirmation of this deep interaction. The dynamic and fluid pastoral habitat produces villages without real squares, and public spaces are made simply where, for morphological reasons, the road widens considerably its section or converges with another territorial path also originally a flocks passage.

In short, we are allowed to identify three main modes of behavior of the ratio village / agro system within the complex and diversified Sardinian rural landscapes.

The “center – center” form

Within the cereal open-field, inside the common management system of soil resources (called *Viddazzone*, deriving from the Sardinian word “Bidda”, specifically, the *village*), in the regions of hills and plains, the urban position is available in the most convenient way to support this

system, at the center. Beyond specific situations of institutional or religious nature, which could substantially affect on the definition of landscape boundaries, simultaneous and cyclical use of land in this agro-pastoral sense not only creates an equable sharing of village territory in pasture and arable land but also determines a certain equidistance between the centers, proportionally according to their size. These open landscapes are characterized by little point features of micro-urbanity (rural villages) that underlie a territory proportional to their specific needs.

The characteristic of the compact village of plain or hill is that it is also surrounded by another dense habitat form, the specialized crops one, a kind of food system made of interlocking orchards and of enclosed gardens (*lottus*, *cussorgias*, *binjas*), impermeable to pastures and in clear continuity with the urban tissue.

This belt manifests urban features: in particular, the settlement culture of the enclosure and *hortus conclusus* makes urban blocks and enclosed gardens two events entirely consistent habitat made in a different way. The continuity of the road network, the horizontality of built profiles, the enclosing public space, make the binomial village / agro system an integral and autonomous element with morphology clearly recognizable.

Figure 3. The centered village in countryside.

The “Center-edge” form

It is frequent in Sardinia that the village places itself in a strategic edge site between two major agro systems or between the dominant agro systems and grazing; in this territorial configuration, we're allowed to consider the urban center itself an edge that controls both production systems. This is done in the frequency halfway fluvial systems, in which the space between the river and the town consists of the most fertile land is occupied by peri-urban specialized crops (citrus groves , vineyards , orchards), while the space upstream of the urban pastures or extensive olive groves. In these cases, the landscape is not structured on more centers that colonize isotropically in the territory, but on centers arranged linearly and with an almost symmetrical between land use systems or agro gardens and saltus. This operating center / edge also makes two different types of configurations of urban edges: those upstream definitely closed and protected, sometimes in continuity with fences, pastures, and downstream of high permeability and dense and capillary branching paths to the river. Many of these situations are often near the mouths of rivers, inland, or in the narrow terraced valleys of the interior, in which the cultivated terraces show morphologies and sizes absolutely comparable to urban terraces.

Figure 4. The village between specialized crops and saltus.

The “Center-Saltus” relationship form

In this case, especially prevalent among mountain or hill pastoral habitats, as opposed to the main agro system and inhabited reality are two totally different and distant but closely related. The area of the gardens, occurs therefore also a few kilometers from the center that controls it, very often placed in a dry and arid soils, not very suitable to crops, much more connected to the main paths of the pastures. These villages, in contrast with the village of the cereal open-field of the plains, present themselves as centers with a strong vertical development, with a significant urban projection and a very limited internal porosity.

The pastoral relationship with the large enclosures (*tancas*) dominates the physical configurations of the relationship with the countryside, and as these are very wide, often dramatic antinomy between full and empty spaces. The specialized crops agro system domains, very often arise in the highlands and valleys that characterize the draining themselves are enclosed by dry fences arising from the works of stone clearance of rocky soils that characterize these areas.

Figure 5. The village away from its agricultural domains.

This concise classification of rural Sardinian villages on the ground of relationship with its closer agricultural domains, shows how this extraordinary continuity of rural landscape, continuity of space and time, permeates all the scales, the one of big territorial organization forms (the hill openfield “puzzle”, the flock passages (*camineras*) net, the *bocage* of agricultural enclosures, the twentieth-century modern reclamations chess-board, the fieldworking strips of Southside urban fringes), the one of urban blocks and of housing dimension, the great agricultural *domus* dominant figure or the mountain simple house “*en band*“, or again the diffuse pastoral farm-houses of island peripheral regions (called *furriadroxius* on Sulcis – in southwest side, *cuiles* on Nurra – in northwest plain and *stazzos* on Gallura, in northeast side).

Figure 6. San Vero Milis. The village and its enclosed domains.

The new ecologies of fringes. Hybridizations urban / rural

It is no coincidence, in fact, that in the smaller towns of Sardinia, which have never completely supplanted the activities related to agriculture and farming, which occurs today this slow and difficult re-appropriation of an unproductive and piecemeal countryside, through a mixture of housing configurations, where the fringe of the original nucleus fabric of *domus*, dissolves into a singular and picturesque morphogenesis of “building-annexed”, into the carpet of polychrome surfaces between urban and rural areas. This form of “landscape of fringes” is a result of stratified processes, the dynamics of which diachronically occurred, uncoordinated and inconsistent, and in which the very presence of the green has more a residuality and isolation character than connection, contributing to diffuse image of patchwork landscape. Within this mosaic of full and empty spaces, buildings and agricultural interstitial, where persists deregulation and the need to take up space for the production and housing, there is an evident concern to organize and live the suburban areas through new rationalities. In contexts such as Sardinia, where rural activities held decisive roles in the landscapes formation as an expression of a specific social economic fabric, this hybridization with typically urban settings, generates discontinuity and inconsistency factors which necessarily reflected in the new rural habitat

types. This, in indirect farming system, in part derives from the incompatibility between a 'building that is substantially related to the sharecropping activity generated by social and economic needs and the current one oriented towards only to economic development. Also in the rural systems in which dominates the ownership and direct agricultural management, as we have seen, we are witnessing a shift in housing and in other urban functions to holdings, especially situated in peri-urban areas, thus altering their historical relationship with the landscape. This process therefore occurs not only in territorial scale, in which the historical structures gradually change or they are subject to a new logic of settlement, «but also involves the domestic space, which - split the original unity between living and produce spaces of the farm - it becomes the space devoted to services and business»¹⁸⁴

This change in the singular unity of this "rurban" settlement then generates rationalities that are moving more in the direction of a multi-functionality¹⁸⁵ that radically changes the historical concept of rural and urban space. As a result of these processes, these rationalities seem to be made of combinations, unusual juxtapositions between spaces for housing, manufacturing, marketing, in which the domestic space and the public one are often not identifiable and even not physically divided.

The combinations "house-greenhouse", "house-shed", "house-warehouse", rather than the large remittances, livestock farms residential or residences complexes attached to the company craft, witness a sharp re-appropriation of the countryside by the production activities although never related to the traditional concept of the rural space of agricultural production. And yet the direct management of rural areas, since the beginning of the new millennium that had accentuated the possible distance between the places of production and administration and especially the residence, in the opposite direction, seems to be peremptorily returned as a practice of a new extra-urban living¹⁸⁶, a new ecology that distinguishes the nowadays great spread housing crown of main conurbations.

The "urban" multifunctional potential of specialized crop areas.

In this "puzzled" belt of specialized crops that densely surrounds the village, strategically displaced in urban fringes areas and which is deeply rooted in the very nature of the village, are occurring the main mutations in "rurban" sense of the historical landscape, the deeper hybridization between *bidda* and *sartu* (the village and the countryside), historically distinct but highly related. This bond is in crisis today, paradoxically for a new rapprochement of agricultural, livestock farm and handicrafts and housing. And yet, in the current "rurban" configurations of fringe areas, specialized crops participate in multifunctional sense evolution of the countryside and are just essential into the new processes of progressive urban colonization. If we consider that our rural areas, as stated by Bernardo Secchi, as invaded by urban tensions, react and are yet structured for "micro-rationalities" of production, often still closely tied to the fabric of rural society that generated them, we are allowed to consider the specialized peripheral crops as a specific dimension and completely integrated with all these rationalities, or are themselves rationalities, through which the farm or another small generic production unit reached the direct and continuous use of the land.

¹⁸⁴ Durbiano, G., Robiglio, M., from "la nuova dimensione del territorio", in *Paesaggio e architettura nell'Italia Contemporanea*, Donzelli editore, Milan, 2003, p. 40.

¹⁸⁵ These features are described very well by the addresses of the PAC (Politiche Agrarie Comunitarie) in which "multifunctionality" of agriculture activities is a fundamental issue. About this topic cfr. AA.VV., *La riforma della Pac in Agenda 2000. Dalle proposte alle decisioni finali*, Osservatorio sulle Politiche Agricole dell'UE, Inea, Roma, 1999.

Figure 7. Schemes of contemporary rurban house/garden aggregations.

Figure 8. Schemes of contemporary rural house/garden aggregations.

The specialized crops such as residential gardens

It is undeniably the most diffuse issue of rural landscape. Increasingly the suburban specialized crops, especially in the Mediterranean area, are incorporated inside the residence domain at the time when the ancient rural lot, originally productive, it becomes tight housing.

This phenomenon is due to landlocked agricultural parts into the more and more closed net of the city, those rural "vacuoles" mentioned by Gilles Clement in the *Third Landscape Manifesto* in 2006, they become more and more places of the garden or the urban individual tree-private, which represents the new garden of the house. The myth of ornamental plants, the ancient lemon pergola of Mediterranean terraces, the classic bourgeois garden, is increasingly taken up in making suburban neighborhoods into residual peripheral crops and becomes one of the essential factors of the binomial "garden-with-house" of large mesh of *pavillonniers* fabric, within the housing sectors between suburban nucleus.

In Sardinia, for example, the two most important urban areas, that of Cagliari and Sassari, evolved than their suburban crops in different ways: in Cagliari, the ancient crops of olive groves and vines, now on a residual basis, remain as trim farm into long and narrow lots (*Corrias*) and define the main slope of spontaneous settlements in urban fringes that have no more agricultural vocation; in Sassari, a robust and ancient crown of olive plantations is underpinned by the residential expansion, however, that not substitute, rather incorporates it as an internal garden of second homes, or operates a network of suburban micro-accommodations.

The specialized crops as work and play clusters

In many circumstances the tree-crops, such as olive groves and citrus groves, constitute a sort of buffer to protect new residential-productive mix cluster -which tend to operate independently within the non-urban territory. In this case also, the functional shift between a productive and ornamental green and another one for loisir is decisive. In fact, the tree-lined field becomes ornamental windbreak tree-lined for sports areas or a traffic noise barrier for productive and residential enclaves. The residual of ancient belt of orchards and olive groves surrounding these villages, often built over ancient poles of rural production, restores the idea of great productive farming within a complex landscape of encloses: the evergreen leaves of tree-lined or the *Boccage* made of Mediterranean shrub and bush arrangement species contribute to "making-of-privacy" of peri-urban multifunctional farm. This new suburban landscape multiplies the crossing and colonization devices of the soil: alleys, yards, sheds, parking lots, dirt roads, open spaces are entered in the residual cultivated network that mediated the capillary relationship between the ancient village and the pasture territory.

The specialized crops such as peri-urban centers connectors

In no different way, the old and new origin main urban nuclei, belonging to the suburban crowns of the main conurbations, whose growth in the last twenty-five years, often proportionally higher than that of the core, they often occupy large areas of the fringes engaged in special cultivation. The interesting combination between settlements and cultivated crown has generated ever-changing and evolving landscapes, where territorial connections and crossings are developed in a "non-stop" urban-rural and in which the walls of the cultivated fields, orchards and of peri-urban vegetable gardens, are often in substantially line with those of the houses, restoring the close landscaping relationship between the house and the field, the arcades and the rural court, between the market open space and the alley. This continuing situation of dispute for the use of the ground in more fertile areas between the city and the agriculture activities, produces interlayered configurations between urban and rural, in which typological hybridization of different nature buildings is the most common and the most "natural" in the management process of a difficult balance between built-up areas, empty spaces and green spaces. In these rurban areas, the logic of the *interstitium* takes precedence over the traditional one *vacuum*, the ecological corridor than the urban block, the residue compared to the unitary effect.

The specialized crops as new poles of multifunctional agricultural production and tourism

The latest Community Agricultural policies encourage the so-called principle of “conditionality” of the agricultural farming, which as well as ensures the efficiency and quality of the product, it must be as multi-functional core and consumption within the peri-urban rural areas. This fact, from the typological point of view, constituted an important innovation but has made even more complex the definitive shift from monofunctional traditional rural building, on the model of “farm-house”, to aggregates volumes for different functions, more and more specialized. To the original productive nucleus should be added the store, the local dining and consumption, marketing, workshops and warehouses. So, within this multifunctional nature of the contemporary farm, in many cases, the specialized crops dominate the agricultural sectors here although short-distance and absolutely necessary to the survival of the same company. The configurations that can take this relationship is variable: you can think of a real agro-urban village in contexts of intensive agriculture and diversified from multifamily management, small farm-houses into agri-tourism houses.

Study on the sustainable development of urban fringe at the background of urban and rural co-ordination in China

Wu YingYing

Department of Architecture, Zhejiang University, 310013, Hangzhou, China.

E-mail: shelia33@126.com

Abstract. *Since last century of the 90's, with the continuously expanding scales of modernization and the high-speed development of urbanization, as well as a long-term practising on the structure of urban-rural binary economy, urban fringe, as a transitional area derives on the urban-rural region system, is facing great challenges of sustainable development, and a series of contradiction of expansion and protection is becoming more and more obvious. At the background of the urban and rural co-ordination, urban fringe has become a critical point of sustainable development realization in integrating urban and rural areas, on the basis of whole above, this paper selects three different urban fringe of Hangzhou in Zhejiang Province as case study areas, by analysing the non-single factors influencing on the mainly subject, and focusing on the development process of urban fringe and its evolution mechanism, attempting to find an effective approaches on optimizing the distribution of land resources in urban fringe, and establishing a development strategy evaluation system, to promote relevant measures and recommendations for the future development of urban fringe areas.*

Key Words: *urban and rural co-ordination, urban fringe, smart growth, spatial conformity, strategy guidance*

Introduction

Background

Since the 1990s, with the rapid development of urbanization in China, the urbanization has reached to 30.8% by the end of 1998. In 2011, the urbanization has exceeded 50% for the first time. The State of Chinese Cities 2012 / 2013 points out that China's urbanization will reach to 70 % -75 %, by 2050.

Around metropolitan area, as the continuously developing of modernizing construction and promoting urbanization, urban and rural area have shown a mounting blurry boundary between each other, and the traditional urban-rural dichotomy is gradually replaced by the new urban-rural relationship, which is mutually infiltrated and relied on each other. In the spatial structure aspect, there has been a sensitive, rapidly changing area of relatively independent regional unit named Urban Fringe, which is a new transitional area derived from the foundation of urban-rural regional system, and it has been the first choice of urban sprawl. Urban fringe, as the frontier region of non-agricultural constructive land sprawl, and the marginal area of agricultural land protection as well, is the key to controlling the urban scale and guaranteeing the agro-ecosystem. Various forces from urban and rural area are gathering there, inspiring and exposing the contradiction between the urban fringe development and protection apparently. Whether it is from the view of long-term goals or short-term benefit, a systematic study on the land-use of urban fringe, spatial distribution and sustainable development research, has become an urgent task for China's urban construction.

Interpretation of the Urban and Rural Co-ordination

The urban and rural co-ordination, proposing as the economy development strategy, is based on the contradiction of urban-rural social economic structure dichotomy, aiming at establishing a

symbiotic circular economy system of functional complementary and organic in urban and rural area. By changing the imbalance of policy and resource allocation that implemented under the social economic structure dichotomy in the past, with the way of developing urban area to promote the rural growth, transforming the rural feature of poverty and fall behind, improving farmers' production and living conditions, ultimately, achieving an integrated development pattern of suitable level in urban-rural productive development, relatively associated urban-rural industrial development, relatively unified urban-rural policy institution, relatively equal urban-rural dominant position and frequently urban-rural interaction.

In the spatial aspect, it is considered to co-ordinate urban area and rural area, combine the characteristics of urban and rural to make each other mutual penetration.

Urban fringe spatial development status

The case of Hangzhou expansion

Hangzhou's development is a process of rapid expansion. The early days of the foundation, under the guiding principles of vigorously developing in the industry, Hangzhou suburban district has formed a large-scale industrial area, the urbanization begins to sprawl to the urban fringe for the initial expansion. By the early 1990s, with the rapid development of market economy, Hangzhou's construction has dramatically speeded up and sprawled along the urban periphery. The rapid expansion of urban space leads to structural imbalance, shortage of land and other issues, we must take measures to guide urban function. In the year of 2001, the adjustment of administrative districts eased tensions of land conflicts and urban spatial morphology got changed from the original single-center to multi-center.

Land utilizing scale, expansion rate and intensity

The land scale of Hangzhou is 3068 square kilometers and the population is of 409.54 million, the metropolitan spatial pattern has begun to appear. By using remote-sensing image technology, we count the urban construction land area of different period in Hangzhou, and calculate the average expansion rate and intensity. (Table 1, Table 2)

Table 1. Land utilizing scale of Hangzhou (Urban Master Plan of Hangzhou, 2001-2020)

Year	City Area			Downtown		
	Land scale (Square kilometer)	Population (million)	Average (Square meter per)	Land scale (Square kilometer)	Population (million)	Average (Square meter per)
2000	229.01	253.72	90.26	204.75	238.26	85.93
2005	290.39	313	92.77	256.53	284	90.33
2010	354.76	362	98.00	304.70	319	95.52
2015	399.96	404	99.00	334.65	345	97.00
2020	453.00	445	101.80	369.92	370	99.98

From the expansion area in different district, the rapid expansion of urban land-use in Hangzhou has an increasing impact on urban fringe. The sustainable development of urban fringe should be studied on the basis of this background that fully understanding the economy development and rapid urbanization.

Total	326.67	471.58	867.95	145.03	396.37	18.11	44.04	5.54	9.34

Land-use changes in urban fringe

According to the changing situation of urban space in Hangzhou (Figure 1. and Table 3.), from 1988 to 2004, the central area of Hangzhou has expanded by nearly six times, and the urban fringe area expanded by 3.5 times as well, while, the rural area has reduced by nearly 20 %. Hangzhou is still in the process of expanding rapidly, and the urban fringe expansion is the most furious.

Land-use and urban fringe spatial morphology features

By the Hangzhou urban fringe range chart in three periods of 1988, 1998 and 2004, we can get the general expansion trend of urban fringe area and built-up area.(Figure 2.)

A. Concentric expansion trend

Part of the main city urban fringe, whether it is inside or outside, the boundaries of the border are in the form of concentric ring that constantly pushing and outward, showing the evolution tendency of developing from the center to the edge.

B. Road - river trend

Through the investigation of external edge, we can see the urban fringe belt's extension characteristics of plan morphology. Urban fringe belt and its built-up area are presented with the shape of rhomboid, reflecting the evolution trend changed from the concentric mode to the finger expansion mode.

C. Trend of satellite towns

There is convincing evidence of frequently contact with the Hangzhou central area, administrative district and satellite towns. On the one hand, the urban fringe expansion was driven forced by built-up area, on the other hand, was affected by the satellite town's geographical tension. All of these, highlighting the stretching of urban fringe belt and built-up area's plan morphology in East-West axis .

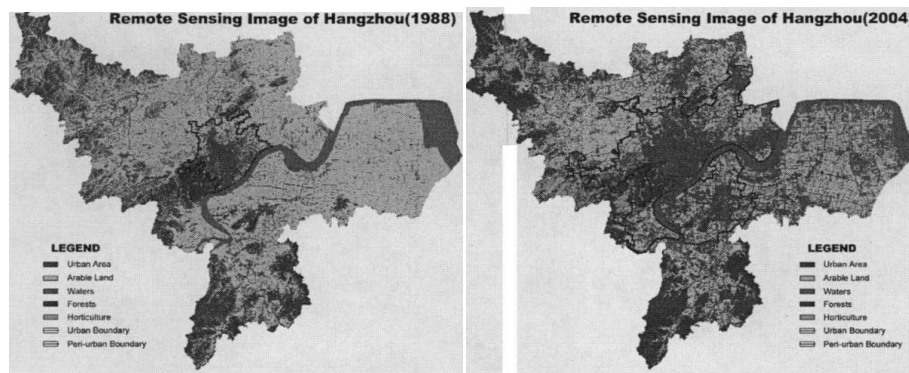

Figure 1. Urban land-use classification by remote-sensing analysis.

Table 3. Analysis of urban space land uses

Year	Urban Area			Urban Fringe		Rural Area	
		Area (Km ²)	Proportion (%)	Area (Km ²)	Proportion (%)	Area (Km ²)	Proportion (%)
1988	Total Area	30.9	0.93	145	4.36	3151	94.7
	Construction Scale	22.3	0.67	66.9	2.01	400	12.02
	Agricultural Area	1.96	0.06	53.25	1.60	1956	58.79
	Forest Area	0.96	0.03	8.61	0.26	499	15.00
	Water Area	5.7	0.17	16.15	0.49	298	8.96
2004	Total area	210	6.3	652.4	19.6	2464	74.1
	Construction Scale	176.7	5.31	290.37	8.73	485	14.58
	Agricultural Area	16.75	0.50	237.05	7.13	1003	30.15

	Water Area	6.63	0.20	68.26	2.05	357	10.73

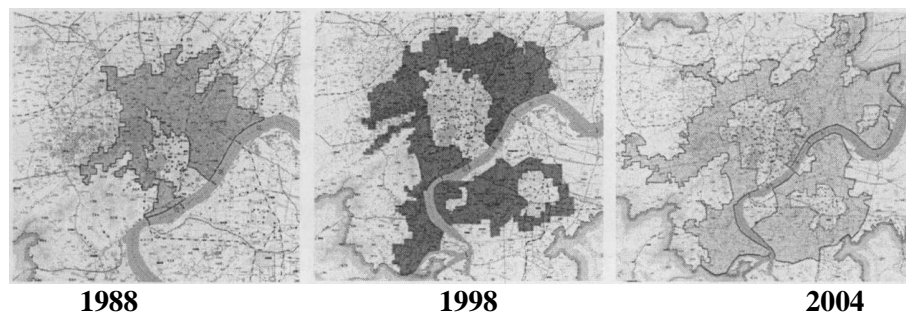

Figure 2. Each period of Hangzhou urban fringe range.

Relationships between the population and urban fringe development

The characteristics of urban population spatial agglomeration and diffusion are extremely significant aspect to interpret the urban internal spatial structure model. Studying on the demographic changing charts in three stages various form 1964-1982, 1982 - 1990 to 1990-2000, we can obviously see that during the period of 1964 to 1982, changes of Hangzhou urban population is relatively small, and the central area population has emerged signs of decentralization, however, the population decrease was minimal (Figure3.). In 1982-1990, the urban center's absolute quantity of population is reduced by 11.86%, which indicates that the

central area has such suitable scale of diffusant source. The distant suburban population declines, and the suburban population growth rises, showing that the suburban area has been the main part of attracting urban population (Figure4.). In 1992-2000, the entire central area of negative population growth rate increases, and the distant suburban population growth rate decreases, meanwhile, the suburban population growth is considerably highly improved. (Figure5)

Development types of urban fringe in Hangzhou

Hangzhou urban expansion is affected by multiple factors, such as, population urbanization, economy agglomeration, industry suburbanization, development of science and technology park, and construction of intercity transportation infrastructure. Through the integration of research and summary, Hangzhou urban fringe development types are mainly in these following categories:

A. Type of mainly based on the recovery of culture and landscape, and the development of tourism and residence. For example, XiXi Wetland and Jiang Village, which are characterized by estate agent as the vanguard of spontaneous market force.

B. Type of ecology protection and control of urban development. For example, Zhuantang district, which is characterized by achieving the coordination of overall urban and local benefit of urban fringe development under the way of urbanization.

C. Type of the construction of high technology park. Such as Binjiang district, which is completely developed under the leadership of local government.

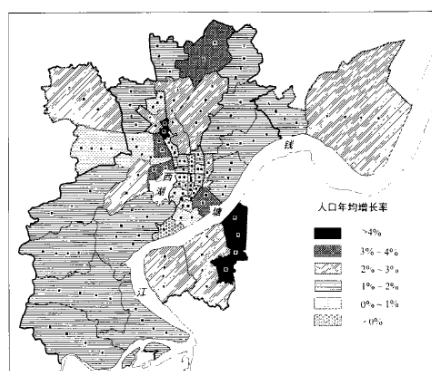

Figure 3. 1964-1982, Spatial types of population changing in different blocks of Hangzhou.

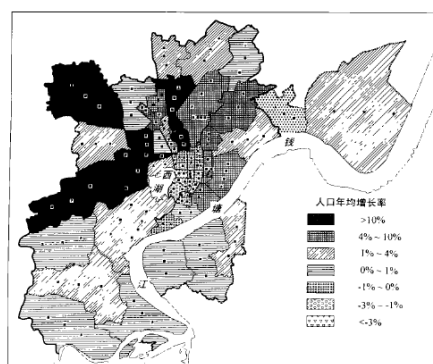

Figure 4. 1982-1990 , Spatial types of population changing in different blocks of Hangzhou.

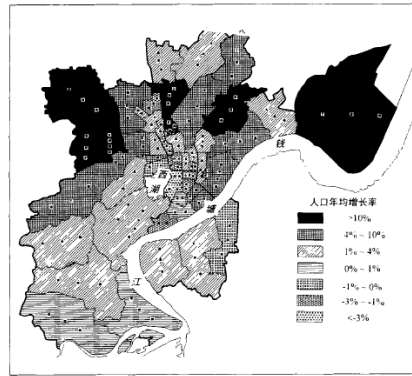

Figure 5. 1990-2000, Spatial types of population changing in different blocks of Hangzhou.

Explore the evolution mechanism of urban fringe development

The evolution mechanism of urban fringe

Urban Fringe is a unique human environment system, which should be due to the interaction of various factors and powers including urban nature, economy and cultural environment system. Each aspect of the urban fringe developing changes is related to the different element of the whole urban environment system, and has maintained a close spatial relationship with urban area, relying on each other. Among the all factors, urban economy activity is the determining factor of the urban fringe development, industrial activity is the direct motivity of the urban fringe development, furthermore, the content and pattern of industrial activity determines the urban fringe spatial structure and land-use morphology characteristics.

Urban fringe internal evolution mechanisms, essentially is the result of joint action that the urban internal development pressures working on the suburban area and the needs of urbanization of suburb. The existence and development of urban fringe entirely rely on the pressures of urban development, the imbalance of all these pressures in different directions, is the direct cause leading to imbalanced changes in urban fringe. The factors, affecting urban fringe spatial development can be summarized in three aspects: promotion mechanism, basic mechanism and support mechanism. (Figure 6)

Promote mechanism: The spatial requirement that urban economy development has to be faced with, is the motivity resource of urban fringe spatial expansion. Urban continuous development, on the one hand, is to make the urban function and structure complication and diversification, upgrade traditional industry, rise the related peripheral industry, and increase the spatial resource demands of urban, on the other hand, economy development has attracted a large number of non-agricultural population congregated, which stimulates the urgent spatial resource needs of urban. Industrial development and population congregation makes the urban create a strong model of developing from the internal to external, which is a spur to seek ways to the external expansion.

Basic mechanism: Transportation system construction, transformation of lifestyle of production and living that promoted by technological development, and the influence of the natural conditions, all these above have become the basis of the spatial evolution mechanisms of urban fringe, which is the main support to realize the possibility of spatial evolution. Building a modernized transportation system has greatly increased the individual action distance, at the same time, the construction of modern logistics system in the internet age, reduces the individual spatial distance of seeking service and information. Traditional urban structure has got shocks by the reciprocal relationship in distance. The superiority of central area information has gradually weakened, a real external expansion has achieved to form a various group pattern.

Support mechanism: Urban planning and policy regulation is the coordination mechanisms

of urban fringe spatial evolution. As a subjective form of coordination, the establishment of policy regulation and the formulation of urban planning play a role in promoting or limiting the urban expansion. Among these, the whole urban planning policy, urban development policy, related land-use space and industry development, which are all formulated under the guidance of national macropolicy, have a direct impact on the development of urban fringe spatial morphology, as well as the provisions of the regulations and macroeconomic policy form an indirect impact

Form the structure diagram of governance evolution mechanism

The phenomenon of urban sprawl development is a consequence of various factors, we should consider the governance measures in a systematic standpoint instead of a single aspect, and on the basis of the conclusion of western countries' management experience, combining with the current reality as well.(Figure 7.)

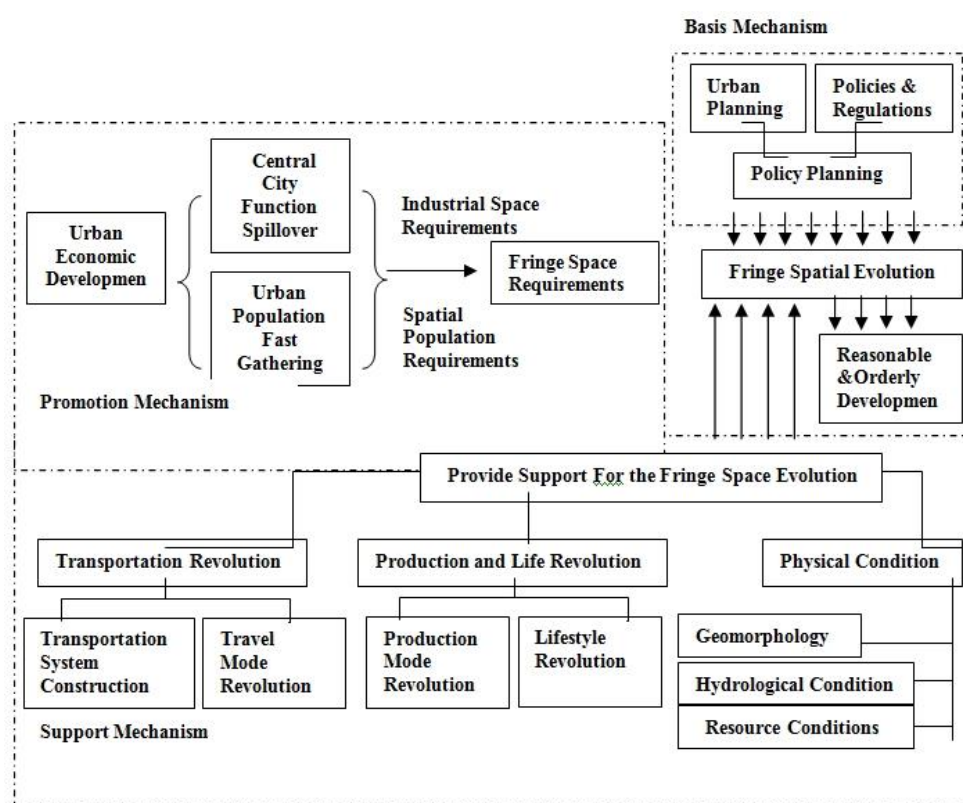

Figure 6. Analysis of the evolution of urban fringe.

Figure 7. Governance mechanism of urban sprawl.

Select the case of urban fringe

XiXi wetland: recover culture and landscape, develop tourism and residence.

XiXi district is located in the westnorth part of Xihu district in Hangzhou with the total area of 23.06 square kilometers. In the process of XiXi district development, the government of Hangzhou has formulated a series of related planning and made decisions to consciously guide the recovery of culture and landscape, and achieving the sustainable goals of the development of the tourism and residency, which mainly including:

- A. 'Jiang Village phenomenon' and improvement of the basic infrastructure
- B. The construction of XiXi Wetland Park and cultural tourism
- C. Provide employment chance for the farmers and other related security

Zhuantang district: ecology protection and urban development controlling.

Zhuantang district is located on the southwest part of urban fringe with the total area of 156.32 square kilometers, which is an essential place of the golden tourism line. In quite a long period of time, Zhuantang district has been incorporated into Hangzhou scenic tourism and urban water conservation district, and takes the function as the industry base of agricultural production. Since 1990s, the whole Zhuantang district developed slowly and had a poor economy foundation, which become the 'lagging region' of Hangzhou's economic and social development. In 2006, the government proposed to develop economy to achieve the goal of controlling the urban development under the protection of ecology. The planning decision including:

- A. Tourism scenic spots protection and tourist facilities development
- B. Ecological belt protection and developing planning
- C. Education facilities construction
- D. Pollution prevention measures
- E. The agriculture support for the valuable culture
- F. Financial compensation

Binjiang district: develop high-tech skill and construct eco-creativity park.

Binjiang district is located on the South Bank of Qian Tang River with the total area of 73.33 square kilometers. At the beginning, in the face of 'agriculture, rural, farmers' and the blank situation of urban infrastructure, the government put forward the main objective that combines the high-tech skills development and economy promotion. The developing orientation of Binjiang district ranges from a single high-tech industry development district at first to a combinational functions of education, business and dwelling, which moves towards from the 'West Lake Times' to the 'QianTang River Times'. The planning decisions including:

- A. Building technology innovation base, high-tech industry base and the most dynamic economy growth district
- B. Set up the 'White Horse Lake' creative park as the foundation of the urban organic renewal, ecological environment protection and creative industry .
- C. The improvement of living development and basic facilities
- D. The favourable tax policy and independent budget system
- E. Re-employment training for the land-lost farmers

Summary and reference

Through the spatial development strategy analysis on the three cases above, the advantages and disadvantages of sustainability of content, implementation results and decision-making process

can be easily found out. The existed problems on sustainability of content can be summarized as paying not so much attention to the guidance of land layout in the future, compactly efficient land developing, effective usage of resources, reduction of the social differences in groups and achieving the social equality. In the aspects of implementation results and sustainability of decision-making process, there are issues that the insufficiency of public participation, and lack of the effect evaluation after the formulation and the feedback correction system. Of course, the spatial development strategy of three regions also play an effective role in promoting the sustainable development of the whole urban fringe in Hangzhou and provide some experience.

A. The reference of 'XiXi mode'

During the process of urban sprawl, natural resources are often difficult to be got effective protection. As the accelerating pace of development, natural environment and historic relics are the common phenomenon of a significant recession. Some local governments in order to pursue the economy benefit, fail to attend to the protection of natural space. The protection of Xixi wetland displaying the importance of natural ecosystem protection that government attaches to, is an innovative meaning practice of urban management, which tells us how to protect valuable nature resources in the process of urban sprawl with sustainable development based on the fundamental concept, how to find ways of ecology protection among the battle of the benefit of economy, society and environment, and how to explore a new style of protection and utilization in the urbanization.

B. The innovation of 'White Horse Lake' style

Binjiang southern district construction tasks are identified from four fields, such as economy, culture, spatial quality and development model that are the most basic elements of urban city.

Economic 'transmission mode', which actively cultivates new leading industries, stresses the mutual supporting relationship between the new - old industry and the new - new one, emphasizes the positive interaction between the industry and environment on the original industrial basis. Culture's 'growth mode', which focus on the heritage of urban tradition protection and the cultivation of mechanism's sustainability. Living space's 'quality mode', which is unified with the goal of the whole urban construction and is raised to the height of a kind of productivity.

C. Thinking about the 'Jiang village phenomenon'

In the process of urban fringe development, the market force tends to be a effect can't be ignored. Developers can often lead to drive the region's initial development because of the market sensitivity and profit-driven, however, as the approach of 'isolation', which leaves a lot of problems in the west part of the city during the early days. Although, there are improved facilities in each neighbourhoods, the whole basic infrastructure is still in absence. During the development, because the lack of necessary preparation of the uncertainty about the future, planning following with the developers leads to a state of disorder and confusion about the urban development space. Developing the urban fringe, we must strictly implement the principle of 'planning in advance' to continue the sequence of the holistic urban city and achieve the sustainable development.

D. The advantages and disadvantages of urban space development mode under the leadership of government

The development of Binjiang district is an entirely typical case of urban fringe development under the leadership of government. Some scholars have pointed out that the evolution of urban development and spatial structure in China is largely depended on the result of institution changes. The local government can directly intervene the urban space resource by the executive power, which shows a strong state of government leading.

When in the face of the fierce competition of external environment, the executive power can often produce a strong priming effect quickly, and thus the development of urban space that is implemented under the guidance of the local government, has a significant positive influence on the rapidly gathering superiority resources, promoting the urban structure adjustment, improving the appearance of urban landscape and enhancing the urban competitiveness. What's more, we should notice that the transformed local government, market and public has produce a

profit misalignment.

Propose the sustainable space development strategy of urban fringe

The concept of sustainable development in urban fringe is an important part of the overall urban sustainable development. The power of sustainable development is consist of economy development ability, social development and stability ability, resource environment ability and management coordination. This kind of sustainable development pursue to reach a state that the common development of urban and rural area, and the coordinating construction of economy and environment. It promotes social equality and intergenerational fairness in the course of urbanization, and emphasis on meeting the demand of urban population, rural population and foreign population, and rational allocation of existed resource as well, which not only think seriously about the economy development, but also pay more attention to the social progress and environmental ecology protection.

Hangzhou is a city of rapid urbanization. The city, urban fringe and suburban area are all in the fast evolution, at the same time, the economy, society and land-use structure of urban fringe is abrupt changing all the way, which requires effective urban development strategy and spatial planning guidance and regulation. By the sustainability assessment of regional planning strategy in the case of Xixi wetland, Zhuantang district and Binjiang district, we propose some following suggestions for the sustainability of urban fringe spatial development in Hangzhou.

A. At the stage of urban rapid expansion, in order to keep the reasonable orderly development of urban space and coordination of economy growth, social development, and ecological environment protection, we need effective development strategy, spatial planning guidance and regulation. How to maintain the consistency and unified implementation in different strategy and planning, how to keep the coordination of planning in different period, are both the issues we should pay attention to of Hangzhou urban fringe development.

B. For the development of Hangzhou urban fringe, we need to emphasize the relationship with the whole city from the aspects of functional orientation, construction scale and logical urban form. With the space expansion and the aggregation of population and production, we should form the division coordination of urban function, and set up urban traffic system to ensure the sustained performance, also, we need to solve the coordination operation to build a suitable working and living environment.

C. During the process of urban fringe development, there is a most prominent contradiction between the farmland, ecological space protection and the land for construction. On the one hand, it is the requirement of country and urban's long-term benefit that try to protect the farmland, water and other natural space, on the other hand, it is the industrialization and urbanization which need a large quantity of land space. It demands that improving the efficiency of land-use construction by the study on spatial planning and development strategy is an urgent task.

D. During the process of urban fringe development, farmers are always the vulnerable groups, who have lost their production and living land because of urban sprawl. The government should use a variety of policy methods to arrange their residence and ensure their living life. It is a strategic work that will make a close relationship with the stability of society and long-term development.

Conclusion

Urban fringe's sustainable development is inseparable from the basic conditions of urban and rural co-ordination. From the perspectives of urban and rural co-ordination, there is of positive significance to study the structure of urban fringe spatial development, explore the evolution of urban fringe development mechanism, seek the countermeasures for space sustainable

development, play an important role in coordinating urban-rural relationships and promoting region development and so on.

However, urban fringe development is a dynamic changing process throughout, and has its own particularity. This paper is just based on the research data of Hangzhou, and making a preliminary study of the process of urban fringe development evolution and characteristics. There are still many questions to be discussed and solved in the future.

Contributions to the study of urban morphology: morphological, typological and landscape interrelationships in Brazilian Jesuit architecture

Fabiano Vieira Dias¹, Martha Machado Campos²

¹Faculdades Integradas de Aracruz (FAACZ-ES), ²Universidade Federal do Espírito Santo (UFES). E-mails: fabiano@urbearquitetonica.com.br, marthamcampos@hotmail.com.

Abstract. *The hypothesis put forward in this article is based on the possibility of Jesuit architecture, in particular, located in Brazilian territory (16th century), and brokering dialogue built on the same body, and interrelated manner, aspects of urban morphology, typology and landscape. Lamas explains that, as a discipline, urban morphology adds to itself not only the built environment, but the means by which this was built in its interaction with urban form, ie "social phenomena, economic and other engines of urbanization" (LAMAS, 1992). Understanding the urban form is to understand its elements, "both in order to read or space analysis both in order to design or production" (LAMAS, 1992). Studying urban form means understanding where it enters the city and its constituents, its spaces and the interrelation between them and their context in a comprehensive spectrum of what is called the city and urban. The architectural typology and urban morphology are connected at the heart of their analyzes, whereas both, according to Pereira, studying "two orders of homogeneous facts" (PEREIRA, 2012), studying the components of the city - architectural and spatial - that overlap or complement according to the scale of analysis used. The Jesuit colonial architecture models Brazil, in a decisive way, the construction of distinct urban cores originating in the Brazilian coast in the sixteenth century. This by deploying edilicia typology accompanying the Jesuit doctrine of location and site selection for its buildings, recommending security, visibility and ease of access around rivers or the sea. These constructions carried out on elevated areas marked in time and space the landscape of the first Brazilian urban core.*

Key Words: urban morphology, typology, landscape, architecture jesuit; Brazil

Introduction

The city as a center of human culture builds great narratives of architecture and urbanism over the time¹. These narratives are cultural products that communicate and translate to a greater or lesser extent, as time passes, the quality and shape of the space and the landscape is constantly changing and reframing their content, mostly cultural. In this article, the typological analysis reaches its understanding from the articulation with the urban and landscape morphology. So comes the understanding of the transformations of cultural content of a given time and place, or even changes the meanings of such content. Therefore, the inclusion of the landscape as part of the typological study is relevant. Besides the typology and morphology, include the landscape as one of the narratives of architecture and urbanism, which helps in translating the object of analysis on canvas, provided that such narratives are hinged together. As Milk (1991) explains, the landscape changes constantly as the prevailing cultural content. However, when inserted in the urban environment, binds temporally morphology and typology. At the same time, the construction of the connect type urban form, or morphology of the city, also constructs the image of the city in specific time and space. The landscape under the parameter of urban development complete the history of the city, constituting perhaps one of his most compelling narratives.

Therefore, this article proposes to elucidate the connection between three major narratives of architecture and urbanism - the typology, urban morphology and landscape - and as a last level, investigates the role of architecture in the constitution of the city, taking the type as conductor

initial analysis. Assume, therefore specifically, the study of Jesuit architecture implemented in Brazil in the XVI century, the understanding of spatial relationships that surround it. It is about seeking to elucidate the morphological construction of Brazilian colonial city through typological analysis of Jesuit buildings in an attempt to understand how this typology interferes, builds, rebuilds and replaces landscapes, in different times and spaces.

The Jesuit architecture in its European origin, introduces new aspects in the typology of religious architecture, reflecting the *modus operandi* of this order itself. Founded in 1540 by Father Inácio de Loyola¹⁸⁷, the Society of Jesus is characterized as an effective religious arm of the Catholic Church, to act directly on the catechized peoples and for those that will be catechized, imposing and adapting itself to new cultures that are the incursions of Portuguese overseas trips of the XVI century.

Patetta in citing Alois Riegl, explains that the birth of the Society of Jesus himself comes against political Counter-Reformation of the Catholic Church (Patetta 2012), in his political-religious struggle against the advance of Protestantism over the Christian world, and primordially on the new world discovered by the great navigations, initiated in the late fifteenth century. On behalf of the Church of Rome, the first Jesuits arrived in Brazil in 1549 - almost ten years after the creation of the Order - as part of a new crusade (Ribeiro, 2006).

The partnership between the Portuguese Crown and the Church, especially through the Society of Jesus - not forgetting the role of other religious orders - induces the mode of occupation of Brazilian lands. According to Freyre, unlike the occupation of other American colonies for Spanish, English and French, the Portuguese colonization is characterized by being more open to foreigners, importing only the settler who arrived was of "faith and Catholic religion" (Freyre 1999 : 29).

Carvalho says in his work of catechize the "Gentiles" (Carvalho, 1982: 11), the Jesuit Order has in its doctrinal basis fixation on earth through the creation of religious buildings in urban centers have started as villages or seats of captaincy or the creation of new urban centers such settlements and missions. These centers would be the radiators of the Catholic faith in new lands. The Jesuit installations serve to both the Indians as legitimate or interracial children of Portuguese with Indians (Carvalho, 1982).

The first decades of colonization still had in the presence of the Jesuits the power of the first laws, which required control of European culture on the social, economic and spiritual life of the Indians and settlers. Specifically on the Indians, this culturalisation on European molds occurs in Jesuit domains in their properties deployed on Brazilian ground. Freyre discern how the Jesuit European cultural influence was, in his words, "deleterious" to the indigenous culture, to a greater or lesser level. In the Jesuit missions and settlements in accordance Freyre (1999: 153), "the assembled Indians out of their system and integration with nature" are segregated and protected from slavery and European settlers, but are integrated in a artificialized life transformed into men and women "incapable of have independent living and natural development", concludes the author (Freyre, 1999: 153).

Different situation, or more "friendly" as Freyre explains, for those who "enjoy missionary work, not with eyes of devout apologist or sectarian Society" (Freyre, 1999: 152), there is found among Jesuit colleges, where instead of segregation, the children of Indians or already mestiçados are treated as equal to the sons of Portuguese settlers. The central courtyards of the colleges were the meeting place of the two "races" of dominant and dominated, says the same author, "meeting and amalgamation of indigenous traditions with European; trading toys; word formation, games and crossbred superstitions" (Freyre, 1999: 153).

¹⁸⁷ Officially as a religious order linked to the Catholic Church, the creation of the Society of Jesus was given by the Papal Bull *Regimini militantis Ecclesiae*, of September 27, 1540, signed by Pope Paul III. See in particular: Oliveira, Beatriz dos Santos. *Espaço e Estratégia considerações sobre a arquitetura dos jesuítas no Brasil*. Rio de Janeiro: José Olympio / Uberlândia: City Hall, 1988: 17.

Jesuit typological references: hypothesis of its origins

For Costa, the "modern, post-Renaissance and Baroque" jesuit spirit (Costa, 1941: 10) is unmistakable part of the Order, both in their doctrine as in their art and architecture, even if that has passed in the centuries by changes in their aesthetic, technical and formal patterns. Born in the first decades of the century XVI, in the ends of the art and architecture Renaissance (Costa, 1941), their constructions of this first century are characterized by "programs" and "aesthetic guidelines", called by Patetta of "pauperism" (Patetta, 2012: 390). It is the art and architecture as an expression of faith by unassuming, dedication and self-sacrifice, discipline and order of religious life, says the author.

The stylistic flexibility of the Jesuit production determined that its art and architecture were opened to "mannerism experimentalism, until the formal and decorative triumph of Baroque in the century XVI and the Rococo in the next century" (Patetta, 2012: 390). And further, this flexibility has enabled the Jesuit art and architecture to "adapt to historical situations, cultural developments and the conditions of society" (Patetta, 2012: 391), not retaining on styles, but in local and symbolic needs. To Patetta, in fact, this flexibility or adaptation expresses a "typological experimentalism" (Patetta, 2012: 391), characteristic of this religious order, making it impossible to disassociate their architectural production of their typological historical experiments:

(...) It is not possible to talk about of the "jesuit architecture" without discern between a first period, of the century XVI, characterized by typological facilities and very simple, austere and functional decorative apparatus (in which utilitas and firmitas relied more than venustas); a period between the century XVI and XVII which saw the foundation of important head offices and typological pontualização of the great collegiats complex; a third period (the full century XVIII) based more on the decorative finishing of buildings and scenic than the new foundations (Patetta, 2012: 391)

Such adaptation of the arts and Jesuit architecture to "physiological" changes, as Costa (1941) explains, are only enhance the brand or the "cachet" of this intense production that spreads around the world adapting according to the "conveniences and local resources and style characteristics specific to each period" (Costa, 1941: 10). It made that Jesuits would be different from other stricter Orders in their doctrines, and at the same time, established his identity to them.

Typological origins of Jesuit architecture in Brazil date back to the creation of the Order in the European context, its architectural reference, or references, that represent the expression of its doctrine and ideal of evangelization. This article, in front of studies on a variety of sources, pointing assumptions that, if they are not distinct, may in the end, they can be complementary for the recognition of the origins of architectural typology of the Society of Jesus in Brazil.

Figure 1. In the center, the Monastery of Santo António the Elder inserted into the fabric of the city of Lisbon. Source: Google Earth, 2014.

Both for as to Carvalho Gonçalves, for example, the Society of Jesus has in the medieval monastery of Santo Antão the Elder, in Lisbon, his first architectural experience (Figure 1 and Figure 2). The Company was established in 1540 and the monastery was received as donation from the Portuguese Crown in 1542 (Carvalho, 1982; Gonçalves, 2014). King João III, indicated by previous years (Gonçalves, 2014), receives and installs in Portugal two brothers of faith of Inácio de Loyola - Francis Xavier and Simon Roberts - arriving in Portugal in 1540. Two years later, a small group of Jesuits along with Simão Rodrigues, settles in Santo Antão the Elder "in full Moorish lisboeta" (Gonçalves, 2014: 96). Do this, their first home (Carvalho, 1982) and the basis for the Order be established in Portugal. Santo Antão along with the construction of the College in Coimbra (1548), the later works of the College of the Holy Spirit of Évora (1551) and the Professed House of São Roque (1553), became typological references for future religious works of the priests in Brazilian lands¹⁸⁸

Figure 2. Picture in elevation of the Monastery of Santo Antão, the Elder, in Lisbon.
Source: Google Earth, 2014.

Francisco Rodrigues, cited by Carvalho (1982), points out in his report the architectural features of Santo Antão, which define the building typology of another Jesuit buildings since their beginnings¹⁸⁹: from the concierge, can get to a cloister or "square courtyard" (Rodrigues *apud* Carvalho, 1982: 23) made up of pillars supporting a balcony surmounted and skirted around the patio; the central courtyard, a well water for daily services; upstairs, the bedrooms and support rooms that completed with atelier and another rooms from the ground floor. The building is closed on a court with a small church "devout and collected" (Rodrigues *apud* Carvalho, 1982: 23).

For Santos (1966), however, the typological origins of Jesuit architecture found itself in the first churches built by the Society in Portuguese land under foreign influence or not¹⁹⁰,

¹⁸⁸ In the rapid expansion process, the Jesuit buildings spread over several Portuguese cities from the second half of the century. XVI, reasserting itself in Portuguese territory, while they advance on other provinces, in Europe, coming to Africa (Congo, Angola, Mozambique, Ethiopia, Cape Verde and Guinea), Asia (India, China and Japan) and new World of the Americas. See in particular: GONÇALVES, Nuno da Silva. Baltasar Teles, Cronista da Companhia de Jesus.. Available at: <<http://ler.letra.up.pt/uploads/ficheiros/5270.pdf>>. Accessed on 16 Jan. 2014.

¹⁸⁹ Santo Antão overcomes its importance as the original site of the Jesuits. At the end of the sixteenth century the monastery with his high school constitutes an important place for teaching basic fortifications taught by Jesuit priests who combined in their classes, the religious basis with technical education, the training of future military engineers of fortification, "making them respected as intellectuals, writers, professors of mathematics and other activities" (Oliveira Ribeiro in 2013: 54). Inside the Jesuit Order itself existed priests who beyond assume their cassocks and religious functions, were dedicated to studies and craft of military engineering, also acting on Brazilian ground (Ribeiro, 2013; Oliveira, 1999).

¹⁹⁰ See in particular the work of Santos on the "autochthonous" and foreign hypotheses buildings of Portuguese Jesuit architecture, mostly Italian, from the mid-sixteenth century. Santos, Paulo (1966). Contribuição ao estudo da arquitectura da Companhia de Jesus em Portugal e no Brasil. V International Colloquium on Luso- Brazilian Studies Coimbra: 19-30.

especially in works of the College Church of the Holy Spirit of Évora (1551) and Professed House and Church of São Roque in Lisbon (1565) (Figure 3). From the two, according to Santos, the most important for the Brazilian story is that São Roque, in addition to becoming one of typological reference architecture Portuguese Jesuit, had his foreman, the architect Francisco Dias, sent to Brazil¹⁹¹ for the construction work of the colleges of Bahia, Olinda and Rio de Janeiro (Santos, 1966), since the last decades of the sixteenth century.

Figure 3. Schematic plans of Churches (A) of San Francisco in Evora; (B) of San Roque in Lisbon (1565) and (C) of the Holy Spirit Church of Évora (1551). Source: Santos, 1966.

Studies indicate, however, that only at the beginning of the construction of the Church of Gesu in 1568, with its professed house in Rome, originally designed by Vignola and completed by Giacomo Della Porta and Girolamo Rinaldi¹⁹² in 1575 (Capitel, 2005), that Society of Jesus has its "mother church", Patetta argues (2012: 391). The Vignola's Gesu is not complete before, however, of two projects with plants attributed, firstly to Nanni di Baccio Biggio in 1550 and subsequently a second project attributed to Michelangelo in 1554 (Santos, 1966). In both projects, the cornerstone of the start of construction is launched, but only the Vignola's project remains as final. In projects of Biggio, Michelangelo and Vignola - three architects of "universal renown" (Santos, 1966: 16), have variations of the same type of cross and longitudinal plan (Figure 4), with her arms a little more or less indented; side chapels along the unique nave and chapels in the background, on the side of the altar and apse closing a greater or lesser proportion the end of nave's perspective, embracing the altar (see Santos, 1966 Tábuas VI).

The construction of Gesu (Figure 5) happens in a singular moment in urban history of Rome, and to the very concept of city and western architecture. To Argan (1999), it is the construction of humanist culture throughout the fifteenth and sixteenth centuries in Europe, which brought a new vision of the city, based on the organization of its urban space, the definition of its functions and the creation of a defining architecture and urban space defined itself¹⁹³. Gesu

¹⁹¹ To Lúcio Costa (1941), the importance of the architect Francisco Dias extrapolates the limits of Jesuit architecture built or helped build in Brazil. As an architect, his performance in Brazilian lands has featured in the spread and development of the architecture of the early colonial Brazil.

¹⁹² According Capitel (2005) is attributed to Rinaldi the charge for completing the Jesuit complex of Gesu, projecting their professed house and closing the occupation of a large block of irregular design of the city of Rome. Della Porta takes and completes the design of Gesu after the death of Vignola (Santos, 1966).

¹⁹³ The humanist city, according Argan is a rational conception, derived from the will of a prince by the hand of an architect, base of humanism to be "lay, bourgeois and urban" (Argan, 1999: 58). These urban changes are part of a complex of social, economic and political changes that redefined the central role of European cities in the known world of that age. Part of this urban transformation focuses on the prominence of the architect as part of the explanation of Argan, the "bourgeois split of the city" (Argan, 1999: 58). The liberal, highbrow arts are distinguished from their mechanical and legwork to be created elites of artists who work directly to meet the artistic and urban demands of this new vision of the city (and its sovereign).

therefore born under the aegis of an architecture focused on practicality and adaptability of architectural compositional possibilities, with the city and its urban fabric as a background.

Figure 4. The three plants Gesu of Rome, assigned respectively to the Nanni Baccio Biggio (1550), Michelangelo (1554) and the conclusion in 1575, from the design of Vignola (in the picture the plant appears to work as part of its Professed House). Source: Santos, 1966.

Figure 5. In the center, the Church of Gesu in Rome, with its Professed House shutting in type of court. Source: Google Earth, 2014.

If the Renaissance architecture is governed by a rational ordering of your speech, translating their own faith as part of this new environment, Gesu and later religious architectures, discourse is now clear, second argument of Brandão (1999: 128): an artistic "anti-intellectualism" and "approaches everyday," demonstrating the power of faith over men, having their art as marketing. In fact, the art this time is no longer the middle of the speech, the ideation of the Catholic faith, from itself to be the ultimate representation of the very power of the Church.

This is reflected in the architecture developed by the Jesuits in their expansion across the world. In its origin, is characterized as a mixture of austerity and introspection around a central courtyard, the molds of Santo Antônio, and the Professed House of Gesu. However, while the typology expresses the architectural and urban brand of the Church presence on earth. Initially assuming this austerity, the Brazilian Jesuit architecture accompanying with the passage of time the ideal of aggrandizement of religious space by the art, mainly represented in the work of the panels richly ornamented, represented in the classic text of Lucio Costa, 1941, on the Brazilian Jesuit architecture. In summary, in a range of less than 30 years between the acquisition of the monastery of Santo Antônio and the construction of the Gesu, the architecture of the Society of Jesus establishes the beginnings of its build typology. Based on a flexible and adaptable type,

functionality and meets the symbolism of faith and the power of the Church, while it is ultimately the representation of European culture outside their continent.

Typological origins of Brazilian Jesuit architecture: the church, the fence, the court and the courtyard

As mentioned earlier, the power of the Catholic Church in colonial Brazil was present, primarily through the Jesuit order, one of the first to arrived in Brazil on an unquestionably way. Their religious buildings mark the virgin and untouched kind of the first centuries of Portuguese colonization of Brazilian lands. Deployments of Jesuit buildings, always it can, seek for strategic places on the land to be catechized, regardless of the large availability of land in the early days of Brazilian colonization. According to Carvalho (1982), the Jesuit religious buildings seek a middle ground in the occupied territory, among the first villages of Portuguese colonization and indigenous villages, the latter being his main target for Brazil. Still according to the same author, the proximity of the Jesuit religious complexes with the Portuguese urban cores is providential, because of the eminent growth of the first urban centers in Brazil. Thus, the Jesuit buildings would be in "civil action center to better exercise their religious activity" (Carvalho, 1982: 25).

From there, the places chosen for the construction of their religious complexes are defined primarily by their position in relation to the environment (Figure 6) and, not least important, by the ease of roaming about the territory to be catechized:

Thus, the location of Jesuit buildings in Brazil was almost always on the highs, with beautiful views over the sea and next to a river. The proximity of another building warranty Jesuits easy locomotion: an along the coast, for communication with other centers of catechesis and conversion; and another for the interior in search of Indians and the establishment of new settlements. And the elevation facilitated the defense, and the building itself, by itself, it stood as a fortress (Carvalho, 1982: 25).

Figure 6. Drawing 1758 the Jesuit college of Bahia (BR) and its prime location relative to the sea. Source: Oliveira, 1988.

Free visual obstacles, these high places - mostly - establishing control and dominion over the lands around them and the landscapes that form from the inevitable framing that the openings of the first religious buildings do to nature around. A form of occupation guided primordially on safety of the clergy and their aggregates, living around religious life of the Order. But at the same time, they reflect the human and foreign occupation in these virgin lands, creating, recreating and continually appropriating the surrounding and abundant nature, as part of daily activities, tasks and moments of seclusion of the Jesuits priests.

In a mix of religious building for teaching and dissemination of the Catholic faith and fortitude - place of safety for the community that there was forming - the Brazilian Jesuit architecture adopts formal and functional types that suit both the missionary purposes of the Order as the casualities those unexplored and wild places. The occupation of the land is done at first by the erection of temporary structures (Figure 7), namely: a rustic shelter, almost a hut without dividing the reference is built for exploring the surrounding territory in search of the ideal and to construct the final religious building, besides the first religious activities of the Jesuits in that ground (Carvalho, 1982).

Figure 7. The construction of the Jesuit temporary shelter. Source: Najjar 2011.

Chosen the place in the premises of service protection, location and presence between Portuguese and Indians, initiated up the works with the availability of materials and workmanship site. The definitive work, which was started by the construction of the church (Carvalho, 1982) should reflect the establishment and continuity of the activities of the Jesuit Order in Brazilian territory. In general, as Costa explains the Jesuit religious complexes in Brazilian lands were divided into three parts concerning their religious duties and day-to-day life of priests:

The program of Jesuit buildings was relatively simple. Can be divided into three parts: for worship, the church with the choir and sacristy; for work, classes and workshops; to the residence, the "cubicles", the infirmary and more service areas, beyond the "fence", with garden and orchard (Costa, 1941: 13).

This division of functions was present physical and symbolic form in its architecture: the church (with its sacristy), first building to be executed of the final building, marked the place. It was the church who carried the Christian symbols of the Rome Church and represented, ultimately, European architectural culture that moment. The fence, where was the orchard and vegetable garden or as well as, sometimes, the water well is discordant point between some authors because their position and existence¹⁹⁴. Carvalho indicates the presence of the fence, as reserved space to the livelihood of the priests in their Brazilian complex, and the social and symbolic distinctions of the same, as illustrated below:

In all these buildings were almost always a 'fence'. There were cultivated fruit trees, vegetables, aiming to help the maintenance of the inhabitants of the residence or College. This kind of orchard was fenced (there, the name 'fence'), and Inácio de Azevedo, when he visited in 1568, has forbidden women to enter there, even for cleaning and should be made this deal with men who could hire women to work, but whose entry would be on the outside, not through the Jesuits house. (Carvalho, 1982: 27).

The Carvalho's definition complete what Lucio Costa, quoted above, states the fence as an important part of the Jesuit religious buildings. Cardim describes the College of Salvador in Bahia, 1583 (see Figure 6), with its extensive fence and its access to the sea: "The fence is very large, it hits the sea, in its inside priests will embark, has a perennial source of good water, with

¹⁹⁴ See as an example NAJJAR Rosana (Jan.-April 20112001). Para além dos cacos: a Arqueologia Histórica a partir de três superartefatos (estudo de caso de três igrejas jesuíticas). Boletim do Museu Paraense Emílio Goeldi. Ciências Humanas, vol. 6, n. 1: 71-91.

your tank ... "(Cardin *in* Santos, 1966 note 3: 50). Therefore, the fence conforms with an external place to the building of the Jesuit complex. Even after completion of the building, about the place serves the livelihood of the Order, through the gathering of fruits, vegetables and other plant products, in addition to housing a water well - in some cases - for the supply of the building (Figure 8). In Carvalho's explanation, the fence is not a constant in all Jesuit buildings because it demand, like the rest of the complex, material support and labor to do it.

Figure 8. Detail of the Jesuits property situation in Vitória city, capital of the state of Espírito Santo (BR), in a survey done in the eighteenth century by the military engineer José Antônio Caldas. The building of São Tiago (Ca) complex and the layout of the fence demarcating the Jesuits property. Source: Miranda Ribeiro and Pessoti in 2011 Edited by the author.

In the Jesuit religious architecture the typology repeats in a mixed of physical protection and sacred. The architecture is built at the same time, bound and limited by no more sacred representation of some pagan god, as Fustel de Coulanges (2004) explains, but the Christian God, his church and his clergy. It is Temple and home; palace and fortress; housing, shelter, garden and place of worship and God's presence in new lands. Outpost of the Church, organized and representative of European culture, its architecture superior technical quality, complex compositions and striking symbolism differ it of the surroundings built and natural, becoming, in the town or village, the main building of the early occupation of Brazilian urban centers.

The Jesuit typological complex with its “quadra” (court)¹⁹⁵ format is organized by complementary parts, with marked functions, spatial and formal hierarchies: the court frames the courtyard, while the patio conforms to the block. Both have a higher limit on the fence (regardless of its format and concept), and the church, where was everything began.

¹⁹⁵ This article follows the term used by Lúcio Costa in his article about jesuit architecture, 1941, to meaning the regular design typical of brasilian jesuit buildings, maked by parts with its functions and especific uses that was modeled by the local relief, started always by the church construction that's used to close one of the parts of the block as one of its sides. And at the end, when finished, it give form to the typical brasilian jesuit architectural building. As a rule of translatio, it was chosen to translate the term “quadra” to the english “court” because its proximity with “courtyard”, because of the “quadra” sides that surrounded the central courtyard.

The Jesuit court presents interesting constructive process (Figure 9) therefore creates over time of its execution, historical relations with the urban evolution of the place itself, gradually and slowly, shaping their place of deployment, with characteristic morphology and distinct from civil buildings of that time. Also impressive for its size, height and strong impact on the local environment because it constructed at this time the beginnings of a distinctly urban landscape on the natural landscape.

Figure 9. The form of Jesuit occupation: following, the church building, the main building, and then the continuous process (which could take centuries or never be completed or executed) the closure of the court and the formation of the inner courtyard. Source: Najjar, 2011.

The houses, schools and residences are typical Jesuit establishments of the fixation of the Order in Brazil¹⁹⁶, and its center of "raid" for catechesis of the Indians (Carvalho, 1982). The

¹⁹⁶ Santos (1966) lists the Jesuit buildings and their functions installed in colonial Brazil, which were not limited only to education and faith: "Among the establishments founded included: for education, homes, residences, schools, and seminaries; for catechesis, missionary villages; for the treatment and retreat, the halfway houses or Thursdays of rest, mental hospitals, gatherings, hospitals; and religious preparation, novitiates, where the waves of soldiers leave for his army. Because in fact they constituted an army, even if surprisingly brief given the magnitude of the work undertaken - work more than educational and catechetical, because it starts of the colonizing action itself, built at the best clay - the education and faith. "The farms, barns and mills built by the Jesuits, as the author explains, emerged as a way to aid in the costing of the Jesuit work in Brazilian lands. See in particular: Santos, Paul (1966). Contribution To The study of the architecture of the Society of Jesus in Portugal and Brazil. Coimbra: V International Colloquium on Luso-Brazilian Studies.

differences are related to their function within the Order, but because of an urgent needs of the spread of the Catholic faith in Brazilian lands invariably it takes education as a priority function. These Jesuit establishments are defined based on their location and function, according to Carvalho explains:

The building built in the main portuguese village of a captaincy was always the headquarters for raid operations inside in search of native villages for future settlements. In Portuguese village, the headquarters received the designation house when it was not able to perform the duties from the college, while establishments in settlements received the designation of residences (Carvalho, 1982: 20-21).

Carvalho explains that these differences between colleges and residences are in level of teaching that develop (Carvalho, 1982), colleges addition to being devoted to the teaching of reading and writing Portuguese and the indigenous populations of the colony, they also develop higher education facing training new missionaries in Brazilian lands (Carvalho, 1982). The settlements are formed by Jesuit residences, according to Carvalho, the way of the Order to keep the Indians catechized around and about its religious auspices. These were arranged along a large central square, opposite the church, in houses built by them constantly referred these back, as Carvalho explains, the image of the Indian village. But the great square beyond something aggregator it's the principle of being space and domain Christian and European discipline. At one end of the rectangle to conform the square, one finds the imposing church as brand of the new faith about the customs and traditions of the Indians.

Above left, drawing the Jesuit College of St. Paul, considered ground zero of the city building. Source: Municipal Historical Archives of São Paulo, 2014.

Therefore, in one way or another, the Jesuit Order is concerned to establish or participate in the creation of urban centers in Brazilian territory, such as the Jesuit College of St. Paul (Figure 10), based on a morphological type or constructive typology of urban proportions. As noted, the Jesuit buildings, originally, or were present in the Portuguese first urban cores, the headquarters or villages or the captaincies were in remote areas, however strategically close enough these towns and / or the Indians to be catechized. Its elevated position relative to the rest of the

territory¹⁹⁷ and next to the rivers or the sea ensure proper protection, and mobility needed for their evangelizing missions from inside the captivity.

The Jesuit typological composition: form, function and symbolism

The establishment of Jesuit buildings on the block should be the role of the court typology as a synthesis between architecture (building construction and urban and spatial occupancy) and urban morphology (or part of the urban fabric), introduced as an effective way that has adapted to the hardships of the new uncivilized and unchristian world, the example of colonial Brazil (Carvalho, 1982). This spatial organization that revolves around a central courtyard (Figure 11), open to the heavens, becomes its own form of organization of life and the daily lives of missionaries priests in Brazilian territory, adapting to the harsh and dangerous reality of early colony:

(...) This type of construction was very specific to the environment found in Brazil, since it presented an aspect of fortification, with few openings on the ground floor, in addition to entrance doors (sometimes one on each side of the court) and with freedom within the court where it stood all the movement of work (Carvalho, 1982: 24).

Figure 11. In the picture developed by Santos, from the guidelines Nóbrega, according to Oliveira (.1988: 58), the division of the block for its main functions: A - wing of the church, first to be built; B - wing of priests and brothers, as his permanent home; C - wing of the young men; and D - ward services, the last to be completed. In the center courtyard typical of Jesuit architecture in court. Source: SANTOS, 1966.

For Carvalho, the fact that brand building court in the Jesuits and what differentiates them from other religious orders is the appropriation that their clergy did the central courtyard (Figure 12 and Figure 13). The ordinary meaning of the religious orders was to give to the courtyard an aspect of place meditation, silence and introspection. But in contrast to the Jesuits, the courtyard was a place of service organization's day-to-day, especially in Brazilian territory, feature this, since this use of the Monastery of Santo Antônio, the Elder, in Lisbon, as first home Jesuit.

The Jesuit courtyard expresses the "active life" (Costa, 1941: 23) of the Order, because different from the seclusion that the courtyard represented in other religious orders, the Jesuits was the place of moving priests in their daily educational, religious commitments and

¹⁹⁷ As Oliveira recalls, the case of the Paranaguá College, in Paraná, is the exception to the rule typological of the Jesuits in Brazil, citing Cardim, the priests have chosen instead to deploy his college in high place, a place close to the River Itiberê and "a little more than three hundred feet from the water source, the public fountain built in 1714, and where the ships that arrived at Paranaguá to supply of water" (Cardim *apud* Oliveira, 1988: 39). In explanation of the author, in this particular case of Paranaguá, priests exchanged protection for "extreme functionality" because of "proximity to the port, the trade area; place where we could embrace and therefore have strict control of the most significant events of the metropolis "(Oiveira, 1988: 40).

administrative, students and their banter and exchanges, support for everyday services complex. It was a lot of activities that the central courtyard of all this confluence, constituted in a "noisy creative center" (Carvalho, 1982: 24), because the buildings of the complex that revolved around this courtyard housed the classrooms, dormitories, workshops, administrative and support areas to school and church.

Figure 12. Picture of the inner courtyard of the College and Church of St. Alexander, in Belém city (state of Pará). Source: Ribeiro, 1988.

Instituted by the Company, thinking in problem solving "technical and economic in places of work, derived from inexperience" (Patetta, 2012: 393), it was created six plants of churches adaptable enough to adversity of each place, designed by architect Francesco de Rosis in 1580, for new buildings of the Society in the world at your fingertips¹⁹⁸. Are variations of scale and proportion (Figure 14), in their dimensions, which refer to a first analysis, the design of the church of Gesù in Rome, with its unique longitudinal nave. But, within the types presented were two typological possibilities of plants with three naves, appearing to be extensions of the longitudinal side chapels. In all types was maintained the retracted transept and three apses at the bottom, with formal variations. According Patetta, these plants:

¹⁹⁸ Custódio in a concise outlines the organizational process of the Society of Jesus for creating your architecture to be propagated mainly by the New World. In addition to characterizing their architecture from the functionality of its buildings - the church building, place of liturgy and sacred buildings and the common use and services of the priests (the schools, homes and houses) - the Jesuit organization had need, along the sixteenth century, to establish roles technical and operational support for the construction of Jesuit buildings. The creation of the post of director of construction was important for the initial systematization of edilicia typology of the Society of Jesus. The first was Giovanni Tristano, a lay brother who worked beside Vignola in the Church of the Gesù, establishing the use of longitudinal plan as a single nave and a Latin cross. Others came replace Tristano's function, including Francesco Rosis, responsible for plant-type sent to the new churches.

Effectively, the systematization of the architecture of the Society begins to happen from the imposition of *Instructiones Fabricae et Supellectilis Ecclesiasticae* of 1577, creating the first general guidelines and standards for buildings, as Custódio says, "incorporating ideas drafters, without giving the necessary guidance of architects. "And how full the author, among the drafters of reference for the Society of Jesus are, Vitruvius, Cataneo, Vignola, Palladio and Serlio. It was based on the creation of the Common Rules of the Society, including the architectural, Rosis that creates the sixtype plans which spread the new territories catechized by Jesuit hand. Even though this organization held responsible by the Society at its beginning has been lost with time and lack of control, she was instrumental in creating and establishing the Jesuit identity in the new lands, through a typological construct that according to Custódio, "was the result of both expressing the functional needs as references to iconic works of architecture treaties and the contribution of professionals from different countries." See in particular: Custódio, Luiz Antônio Bolcato. *Diretrizes arquitetônicas e ordenamentos urbanos nas missões jesuíticas dos Guarani*. In: Souza, Luciene Pessoti de; Ribeiro, Nelson Pôrto (2011). *A construção da cidade portuguesa na América*. Pod Publisher, Rio de Janeiro, RJ.

(...) They reveal an elaboration of the original type with varieties of solutions either within the schema itself (elliptical plant with lateral chapels and atrium, plant with a central vain with dome and atrium), both in layout and depth of the side chapels, the apse and transept (Patetta, 2012: 393).

Figure 13. Inner courtyard of the Church and Residence of Kings in Nova Almeida, Serra city (state of Espírito Santo) Source: Loc.alize.us, 2012.

Figure 14. Types of plants developed by De Rossis, 1580, to the Jesuit buildings. Source: Patetta 2012.

For Costa, the typology of churches and their built complexes are architectural parties or "reference" (Costa, 1941: 23), adopted or created "by Jesuit architects, or laymen architects in the service of the Society of Jesus" (Costa, 1941: 23) that have influence and propagating in Brazilian Jesuit buildings. In Brazil, according to the author, are adopted by the Jesuits, four kind of plants which the single nave is the most used typology (Costa, 1941). Churches developed in these kind of plants differ by the degree of simplicity of its parts: the simplest, according to Costa (1941), the first to be built in Brazil, where the chancel and a single nave formed a single body (Figure 15), which were divided "conventionally into two parts by a cross arch" (Costa, 1941: 29).

Figure 15. Layout plan of the Jesuit churches of simpler type according Lucio Costa (source: Costa, 1941).

A second typology, wider, according to Costa (1941), where the constructive simplicity still holds, but there is already a clear differentiation between the nave and the chancel (Figure 16), especially through the smaller dimensions of the latter in relation to nave (Costa, 1941).

Figure 16. Typology which the nave differs from the chancel (source: Costa, 1941).

The third typology with larger churches, mainly from the seventeenth century, where the simplicity of the early days is mixed with more complex compositions (COSTA, 1941). In this typology, besides the characteristics of the former type, are increased side chapels on the chancel (Figure 17) "of greater or lesser depth" are added, according to Costa (1941: 31);

Figure 17. Type of Jesuit churches where the simplicity of its architecture is mixed with more complex solutions (source: Costa, 1941).

And the last type, the churches, as the author explains, are built under the influence of the church of the Gesù in Rome. In this type of church, in particular and the Gesù way, chapels spread along the lateral of the nave (Figure 18), each one with its specific altar. The greater detail is the two mirrored chapels that were closer and just below the chancel, for "they were almost ever wider and taller, if not also deeper, with that same goal to score, the plant, the cross" (Costa, 1941: 31).

Figure 18. Type of Jesuit churches of greater complexity, based Gesù (source: Costa, 1941).

In most instances, was the presence of a tower that made up the whole and at the same time, separating the body of the liturgy - formed by the church - the body of the services and bedrooms, the latter on the college and other dependencies. The towers themselves were one of the striking elements of Jesuit architecture, with little time high in relation to the set in order to balance it between their horizontal and vertical proportions. But, according to Costa (1941) these were not always finished, and were only started after the expulsion of the Jesuits in Brazil (held in 1759), and finished "without regard then, (...) the characteristics of the original building" (Costa 1941: 24). Costa completes the analysis with other elements of architectural composition and construction techniques that close the typological characterization of Brazilian Jesuit architecture¹⁹⁹: the use of eaves on their roofs against the excessive rains of the great in Brazilian territory; the roofs of the towers varied according to the constructive technique and the availability of material and labor in that place (Figure 19); the pediments of churches that in the first Brazilian churches even follow the Renaissance rigor, it enter the Baroque with more elaborate designs (Figure 20); portals that change in number according to the level of detail among the simplest sixteenth century churches until the most worked churches of the following centuries; and lastly, the wings that close the typology of the block with the church (Figure 21), more austere designs, giving due importance and hierarchy to the main church building.

Figure 19. Changes in typological roofing of the Jesuit towers.(source: Costa, 1941).

¹⁹⁹ See in particular: Costa, Lúcio (1941). 'A arquitetura dos jesuítas no Brasil'. In: Revista do Serviço do Patrimônio Histórico e Artístico Nacional. Serviço do Patrimônio Histórico e Artístico Nacional/Ministério da Educação e Saúde, Rio de Janeiro.

Figure 21. The court way and architecture in mixed of residence and fortress (source: Costa, 1941).

The composition of the parties seeking a balance of shapes, volumetries at the same time that purposed the hierarchy of functions and meanings without losing the "visual unity of the whole" (Oliveira, 1988: 59). According to Costa, scenic construction extended into the interior of the church, the principal place of God's presence, joining the ritual and symbolism of the liturgy.

The Jesuit church was a beginning and end, the building symbol of a new way to express and propagate the faith. Since the implementation of the building, with the choice of the ideal place, under the Jesuit security guidelines, visibility and ease of displacement; through its construction which marks the place and the landscape, reaching its way to transmit their faith by the symbolism embedded in its architectural typology, became the expression of this religious order throughout the centuries.

In Brazil, it has become more prevalent in the urban establishment of several towns where the Jesuit Order settled, their buildings were mostly the buildings better finished, more volume and height. Both his buildings and the manner of their priests were, as Oliveira, direct way their relationship with society and its time explains:

The deployment location of the colleges at the heart of the urban core activities, on top of a prime elevation in the chosen place could provide the desired contact with society, the proximity needed to show them their dynamism, their intellectual erudition, his brilliance in various technical issues, their ability in practical matters, and thus their indispensability in the colonial urban daily life. Symbol of militant faith, these institutions only by its placement in

urbe, the sight of his austere elevations, were also a symbol of the new age of reason (Oliveira, 1988: 101-104).

The morphological type in Jesuit block shows the significance in the settlement and expansion in Brazilian lands. In different Brazilian cities, the Jesuits complexes - the church and the court - shape both the landscape rehearsing their urban beginnings as urban morphology, drawing and narrating for centuries, the image and the symbolic significance of the places. Elevated and highlighted front the environment, deployed at strategic locations for the domain and protection, the Jesuit complexes were invariably in their urban cores originating, one of the driving forces of urban expansion over the Portuguese colonization centuries, and even after the expulsion of Society of Jesus in Portuguese territory in 1759.

This way, the typology in urban scale, the Jesuits complexes were involved both in the construction of cities, defining, the priori, the scale of traditional block brought by Portuguese colonization, which was modeled by local relief and their conditioning, but also of its urban landscape - before, it was isolated as an architectural object, which by its own morphological characteristics were able to join the growing Brazilian urban fabric that expanded and diversified the long centuries. His typological flexibility adapted itself to the sinuous design of the first Brazilian cities, as was also able to change positions after the forced departure of the Jesuits. In major urban centers maintained their religious functions, in large majority, but in the hands of the government (Portuguese, Brazilian Empire and Republic) were adapting their duties to the bureaucratic requirements or turned into new symbols of power: the Church out, the State in. In extreme cases, like the ancient church complex and the College of São Tiago, in Vitória city, capital of the state of Espírito Santo, the change of political regime, raised a new aesthetic and a new image for the complex transformed into government headquarters - today, the current Anchieta Palace. The simple architecture of the early Jesuit sixteenth century no longer exist on the new composition of facades, volumes and eclectic decorative elements, the beginning of the twentieth century, also marking the new functions and internal reforms of the building.

One may consider that this is an architectural typology that crossed the country's urban history, experienced its transformations, being a fundamental part of the morphological and landscape constructions of these early urban centers, which can be understood as historical narratives, principiadas, largely by this typology.

Notes

From that exposes Waisman (2013), the typological construct is a cultural process, due to the opening that the types have to external influences. To Waisman, while the type is the "principle of architecture" (Waisman 2013: 102) is also a "historical subject" (WAISMAN 2013: 102), given that in its essence the possibility of transformations, adaptations and "provide the basis for new inventions, maintaining, however, a continuity that could be considered structural basis" (Waisman 2013: 102).

This article seeks to integrate the typology study, from a new meaning their cultural content associated with urban morphology through narrow approach of Jesuit building in Brazil. It also argues that the typology exists only because of its relationship with the city shape, it is a constructive process of cultural projects, covering not only the urban fabric, but all the cultural content that surrounds or fenced throughout history. The type is, ultimately, a cultural and historical example of a moment, not as a model, but represents a not static historical moment, subject to modifications and changes in form, use and meaning moment. Thus, reaffirms Waisman proposition itself, on the type as a cultural element of the story, turning culture in a possible interaction between type and morphology with the landscape.

Finally, the landscape designed and narrated by the Jesuits, specifically in Brazilian lands, it was defined from an urban architectural typology with own meanings about their functions,

integral part of shaping the urban morphology of most Brazilian cities originating on the coast during the sixteenth century.

Abstract. *The Shanghai Alleyway House which was 57.4 percent of the gross residential area in the modern Shanghai in 1949 is the major object of this paper. 2 typical individual house which is a special type of the alleyway house called Lilong Mansions are chosen as the case to take deeper research. And construction is the main and also architectural research perspective. It is discussed in two ways: construction technology and construction organization, and is focused on the particularities of Lilong Mansion as a physical object in the former modern Shanghai. i) Construction technology: the way to take deeper research of the 2 Lilong Mansions case-study objects are based their location; completed time; the shape of their plans, and to the construction level, there are mainly three partial issues: structural system; tectonic style; material. Then by contrastive analysis from these phenomena, the variation of construction technology from the traditional timber-frame style to the brick-wood hybrid style would be acquired. ii) Construction organization: Summing up the information on the construction organization of the alley houses among the archives to find out the features during the progress from the 'craftsman' system to the 'contractor-architect' system. Thus, the research significances come out, firstly, the historical course of how the Shanghai alleyway house developed till traditional Chinese house to the Western-Chinese house could be unscrambled in a more microcosmic way. Secondly, it is also a sort of supplement of the urban morphology study on the modern Shanghai besides the spatial geographic form and the Social cultural form.*

Key Words: *Former modern Shanghai, the Shanghai alleyway house, Lilong Mansion, construction technology, construction organization.*

Background

The Former Modern Shanghai which is commonly defined as the Shanghai from 1943 to 1945, its urban space is a research object containing Historical continuity and Spatial richness. And of which the most typical elements and special forms are the public buildings, public spaces (the Bund and the Nanjing Road) and the mass-developed residential units (the Alleyway House) (Figure 1). What is chosen as the research object is called Lilong Mansion, a special type of the Alleyway House (Figure 2).

The lucid definition of Lilong Mansion is that, the house built for self-living by the land owner which is also called the squire. It differs from the lilong house developed for rent (Figure 2). There's a saying mentioned in the book *Shanghai Longtang* by Prof. Luo Xiaowei in 1997 that, the 'longtang mansion' was another special feature of Shanghai. And it re-indicated the possibility to be chosen as an individual research object. Besides the difference of development and type of owner, the speciality of its physical level and the elements during its construction process also differ from the alleyway house for rent. Which are often embodied as the commodious of spatial arrangement, the variety of material use, the delicacy of details and the mix of different styles, etc. The lilong mansion gives a multifarious cognitive dimension of understanding alleyway house which is a typical element of the urban space in former modern Shanghai.

Besides, to understand the urbanization issue of former modern Shanghai under a dynamic perspective, the research of the physical ontology of lilong mansion provides a strong frame of reference. By the vertical comparison with the different individual cases during its develop

period and the horizontal comparison with other type of architectures in the same time, it has great value to get better understanding of these issues: firstly, the location of the construction system of lilong house inside the whole Shanghai construction system; secondly, the transformation of the construction system in shanghai from the carpenter system to the architectural system; thirdly, the vicissitudes of the physical and social space of former modern Shanghai from vernacular to urban. Compared with taking the economic rationality as the first stage value of lilong house for rent, the construction system of lilong mansion contains rich information.

Figure 1. The Bund, Nanjing Road, typical Shanghai Alleyway House.

Figure 2. The different classification method between former research works and this paper.

Because of the characteristic of self-living of the lilong mansion, it always locates inside a block by individual way as the feature of special distribution. Its building space usually take a role of the catalyst of events (Aldo Rossi, 1966). That means the social and historical elements inside is still typical and abundant, and by the contrast between its special and social structure, we can dig out more information of the former modern city's transformation. This also lead to a

research method of individual case study. That is ‘After answer what, we should also illuminate the social meaning, and analysis in both formal way and social way’ (Lai Delin, 2002).

Case Study

The research method of this period, is that by preliminary calculate the number of lilong mansion in Shanghai (about 300-500), taking two typical lilong mansions as the objects of case study (Figure 3). As what is mentioned above, construction is the entry point of this paper. And the detailed classification method, is that summarized introduction, special functional use, structure, material, decoration and characteristic detail.

Figure 3 the location of the 2 Lilong Mansions.

Case 1 – House Zhaozhou

Summarized introduction: The first case is called House Zhaozhou (Figure 5), its location is No.148, Lane 200, Zhaozhou Road (Figure 4), it's a lilong mansion built before 1920s, and is located inside the third expansion area of the former French Concession. It is 2-floor high and hides inside the block surrounded by lots of lilong house for rent. And the feature of House Zhaozhou differs much from the surrounded buildings.

Figure 4. The location of House Zhaozhou.

Figure 5. Photo of House Zhaozhou.

Special functional use: The special distribution inside House Zhaozhou has obvious functional separation (Figure 7). There are two functional clusters separated by the back courtyard (Figure 6), those are the main part and the assist part. The main part is composed by the principal room, the wing room and a main entrance gate. The principal room has three bays, but actually the two side bays belongs to the wing room. And the principal room has the living room function while the wing rooms have the bedroom function. Turned to the assist part, it contains the kitchen and the maid room function, and on the west top of the roof there's a balcony having both hanger and fireproof function. The back courtyard is the part where mainly used to put the wash basins.

Figure 6. The courtyard.

Figure 7. Function separation: ■ living room ■ bedroom ■ maid room.

Structure: The foundation part is a typical shikumen style, it is consisted of detritus and sand to form a 600mm³ cube. What is built on top of the foundation is the supporting system composed by brick walls and timber frames. The 360mm-wide brick walls surrounds the whole building with 12 200mm²-square timber pillars inside. These combined with the wood rib floor, the triangle roof truss, the purlines and the rafters to form the whole structure system of the house (Figures 8 and 9).

Figure 8. The structure model of House Zhaozhou.

Figure 9. The force analysis.

Material: Turned to the material using, firstly, about the wood use, a large number of the timber material is Oregon pine, which contain the pillars, beams, doors, windows, ceilings, skintles and stairs, and lots of them were made by machine (Figure 10). Secondly, about the brick use, all use the machine made red and black brick with the size $50 \times 120 \times 240 \text{ mm}^3$. They are also used in the brick carving on the outside wall. The outer wall has the width of 360mm while the inner wall 120mm (Figure 10). Thirdly, about the plaster use, the outer wall is in a dry-wall way, with no plaster and with grass-lime mortar as the bonding layer, also with a special pointing called 'Yuanbao Feng'. The inner wall is the same way as the outer wall except the plaster part. It has white lime as the plaster. Fourthly, about the floor part, first floor with red floor tiles while second floor with strip pine floors. The second floor of the west part of the assist room is different, it has reinforced concrete floor. Fifthly, about the roof, it has pine triangle trusses, purlines and rafters. With small bricks called 'Wangzhuan' and Chinese black tiles on top of the roof.

Decoration: House Zhaozhou has a quite mixed decoration situation. The outer side of the main gate is decorated in a western style while the inner side is a traditional Chinese style (Figure 11). The ceiling is western style, but the doors and windows are Chinese style. And the other mix part is the different class from the main house and assist house, there's complicated decoration inside the main house while little decoration inside the assist house (Figure 11).

Characteristic detail: Firstly, There are iron gutter outlets at the eave of the house. Secondly, the reinforced concrete balcony on the roof of the assist house was made for a bi-functional use, one is to be the fireproof ceiling for the kitchen downstairs, the other is to create a space for hanger in the crowded block (Figure 12).

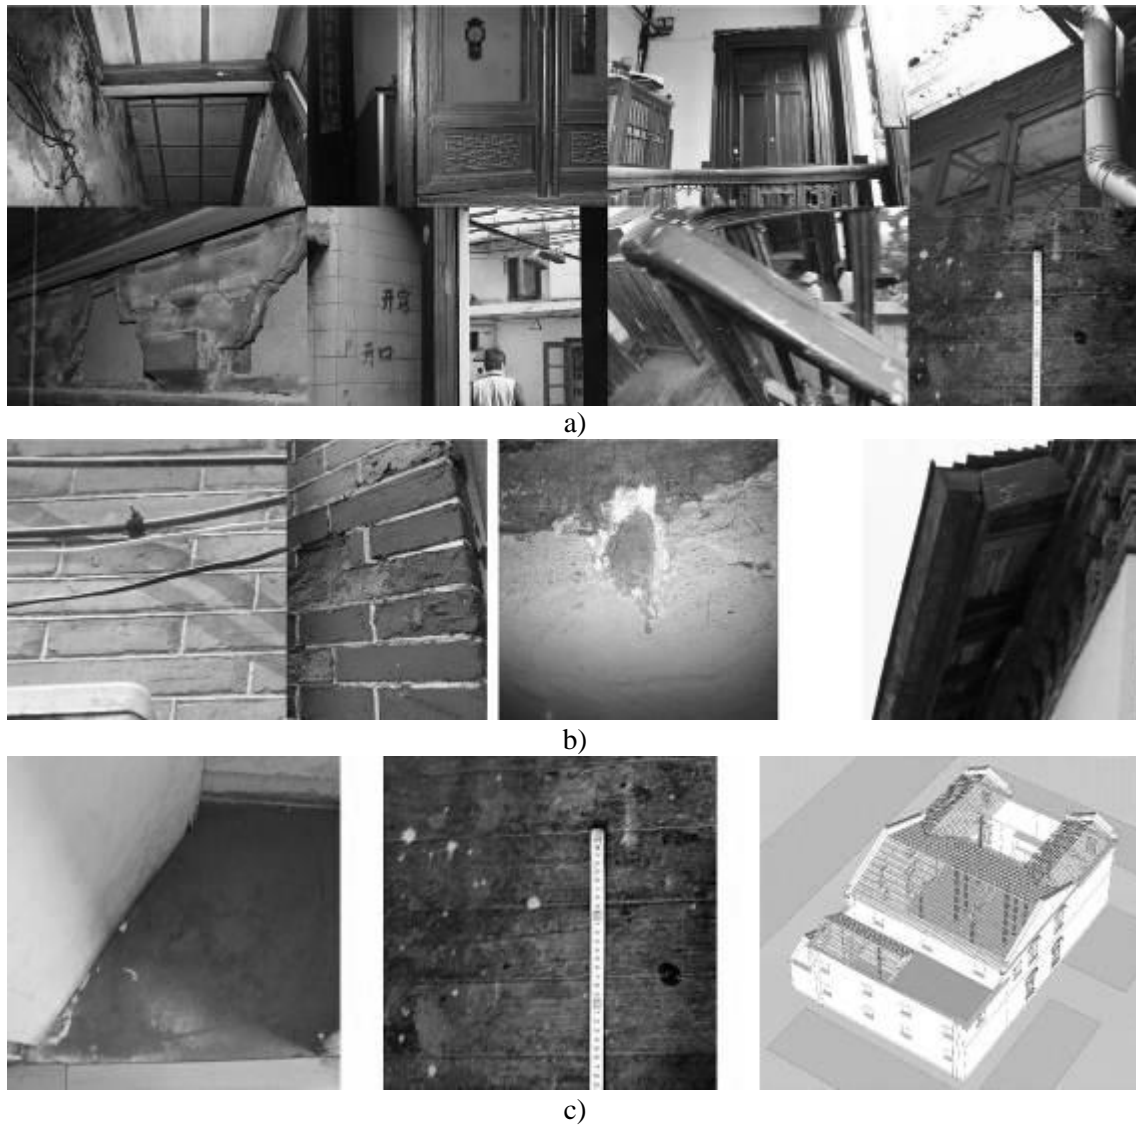

Figure 10. a) Wood material - Oregon pine, and most of them are operated by machine; b) brick material - the outer wall, the inner wall, and the roof; c) floor material - 0F: clay with red painting; 1F: timber floor; 2F of the maid room: reinforced concrete

Figure 12. The iron outlets the reinforced concrete floor of the maid room.

Case 2 – House Yulin

Summarize introduction: The second case is called House Yulin, its location is No.3, Lane 449, Yulin Road(Figure 13), it's another lilong mansion built at 1893, and is located inside the eastern part of the International Settlement. It is 1-floor high, and compared with House Zhaozhou, it's more like a local style house in Shanghai. And also hides at the back side of a row of 2-floor commercial lilong houses built by the owner (Figure 14).

Figure 13. Location of House Yulin.

Figure 14. House Yulin.

Special functional use: The special distribution of House Yulin has little difference with the traditional Jiangnan-Style houses. One principal room with two wing rooms and one gate to form a courtyard space. The inner space has no functional separation with only partition wall to separate the house. But only a small part at the east bay of the principal room has different roof style and this part is used for cooking and washing. The north wall of the principal room set back 1m to make the under-eave space a common corridor connecting the two wing rooms and the principal room (Figure 15).

Figure 15. ■ living room ■ bed room ■ kitchen ■ reconstruction.

Structure: The foundation part is more like the traditional Jiangnan-Style house, use small black brick to form the tube foundation units, which is called 'Hangshi'. What is built on top of the foundation is the supporting timber frame structure system called 'Chuandou' Style. And on top of the timber pillars, the purlines, rafters, tile brick and the Chinese black tile compose the roof part (Figure 16, 17).

Figure 16. The structure model of House Yulin.

Figure 17. The force analysis.

Material: Firstly, about the wood use, all of the timber frames, doors, windows and roof structure are made by a special wood material called China Fir. And all the wood materials are painted by varnish and tung oil to make the color in a wood or dark red (Figure 18). Secondly, about the brick use, all the bricks inside the house are called Chinese black brick. It's a little bit smaller than the late machine-made brick with the size of 40*100*200mm³. But it is also mass manufactured by brick factory (Figure 18). Thirdly, about the plaster use, the outer wall is painted with yellow grass-lime mortar plaster while the inner wall with white lime. Fourthly, about the floor part, the outer floor in the courtyard is made by Chinese black bricks and stripe granite stones while inner floor by bricks and concrete (Figure 18).

Figure 18: a) Wood material - China Fir, and most of them are operated by machine; b) brick material - the outer wall, the inner wall, and the roof; c) floor material - Outdoor: black brick & granite stone; Indoor: black brick covered by cement.

Decoration: House Yulin little decoration except the brackets of the beams in the Northside of the principal room with cloud pattern, the beams cross the under-eave corridor with a moon-beam pattern. There's no ceiling, no other decoration inside the house. About the door and window, no complicated but in a humble way, with only vertical wood batten. And the eave part is also in a traditional way, with beautiful eave tiles called 'Dishui' and 'Wadang' (Figure19).

Figure 19. Decoration of the ceilings, beams and eave.

Characteristic detail: The entrance wooden gate of House Yulin is the most special symbol of a so-called town house for its location is inside the urban area. But the pattern turns to be a really vernacular style which is rare in the Lilong house area (Figure 20).

Figure 20. The entrance gate.

Analysis and Conclusion

After the case study in the construction of the two lilong mansion, I try to put these two samples together with the previous research and make comparisons. This comparison can make sense because firstly, they're both constructed in the concession city after 1843, that is the year when Shanghai started its urbanization. Secondly, although they belong to different concessions, there's little discrepancy in construction system based on the statute. The main conclusions are:

i) The functional separation became more enhanced, and tended to fit with the construction system reciprocally. The conclusion can be draw from the comparison between the two kitchens.

ii) The decoration inside House Yulin has still the vestige of the handicraft from the subtle difference between the same components. But inside House Zhaozhou, all the same components are like copy from each other. That is because they were made by machine. So this shows that way of manufacture has changed from the handicraft way to the machinery way.

iii) Based on the transformation of the structure system, we can see that because of the increasing urbanization strength, there are new demand on the buildings, that is much higher and more intensive. But the structure of House Yulin can't fit the change. For it is hard and expensive to be built higher using 'Chuandou' style, and the structure would be too complicated to make terrace house. So we can find that in House Zhaozhou, the wall becomes more important in structure. The house can be built higher easily and it can be adjoined with other house. But there are still deficiencies in House Zhaozhou. The wall-timber pillar system is unbalanced with force stress. And the structure between the main house and maid house cannot become a unit.

iv) In the previous study, they chose alleyway house for rent as research object. Economic rationality becomes the main issue when being built. So if we put all types together during

1870s to 1920s to compare, there's little difference between each other. And it's hard to explain why the garden & apartment alleyway house have so mature construction system when they first came into appearance at 1930s-1940s. And based on the comparison we did, the conclusion or guess that the types appeared in these period are all transforming types can be established.

v) On the basis of the change in materials, in operating ways, in the styles, decorations and in some panel joint just like the eaves, it's easily to find that construction system was changing at that time. But what was not changed is the house owner always wants to regress to traditional type. This somehow shows that the type of alleyway house was partly transformed from the local type rather than fully transplanted from western style.

The study of Lilong mansion which as a residential type that is not paid much attention projects mass information with cohesion and variety to understand the transformation issue of former modern Shanghai. It needs to be cared and researched with more and more attention.

The effects of urban form on levels of integration of housing schemes and social interaction among residents

Maria Cristina Dias Lay, Márcia Lima

Faculty of Architecture/PROPUR, Universidade Federal do Rio Grande do Sul, Brazil.

E-mail: cristina.lay@ufrgs.br, cia_lima@terra.com.br

Abstract. *The paper investigates how levels of integration of housing schemes can affect social interaction among residents within the scheme and with its urban context, further affecting resident social and emotional health. The study incorporates global configuration aspects and their cognitive dimensions within a single framework in investigating the relationships between man and built environment, more specifically those involving the analysis of relationships between the configuration characteristics of accessibility, legibility and perception of environmental performance. Methodological procedures consisted of post-occupancy evaluation of four low income housing schemes comprised of different layout, size and location in the city of Montenegro, southern region of Brazil. Data were collected by complementary techniques, such as mental maps, interviews, observations of behaviour, physical measurements and questionnaires. Quantitative data were analyzed through non-parametric statistics and qualitative data by meaning and frequency. Following the perceptive approach adopted, user satisfaction and environmental behaviour were employed as indicators of environmental performance and social interaction. Space syntax measures were used in order to analyze spatial configuration as measured by the axial map of local and global integration and analysis of street connections with the immediate surroundings and with different locations in relation to the consolidated urban area. Results indicate that successful integration of the housing scheme in its urban context helps residents integrate into the neighbourhood and the city, increase satisfaction with their place of residence and promote sense of belonging and citizenship, all of which support residents' well-being.*

Key Words: *social housing, spatial configuration, environmental performance, social interaction, resident well-being.*

Introduction

It is argued in this study that Brazilian public housing has been negatively affected by standardization of project design and the nature of the system of provision based on economy of scale, with overemphasized priorities for quantitative targets. Consequently, the design of most housing schemes built so far was not appropriate for the satisfaction of user needs and aspirations and often have common features that distinguish them from the rest of the urban area in which they are located. The attribute mainly identified as usually affecting public housing, is its artificiality – a ‘cyst’ in relation to its urban context. In short, the spatial configuration generally provided in low-income housing schemes is characterized by: lack of relationship with its urban context, as streets designed to serve the housing scheme do not integrate with the existing urban network; low density; uniformity and dispersion, which imply high costs in infrastructure, maintenance and replacements; location on the urban periphery, lack of attractors to motivate surrounding residents to use the environment and integrate as part of the neighbourhood. The repercussion of the number of standardized projects with similar problems in its urban context looked as damaging to neighbourhood residents and to the city as a whole.

Therefore, it is clear that the spatial structure of social housing provided in Brazil and its performance need to be further analyzed in terms of quality, as attempted in this study, in order to identify the relevant factors requiring change and the nature of change that will promote significant improvement in mass housing provision. When bad performance exists, the massive scale and number of those projects in Brazil, which replicate poor quality housing schemes has

been creating a major negative impact on the cityscape, propagating “ulcers” in extensive parts of cities (Lay and Reis, 1994). The consequences of this are predictable, in that the attitudes, motivations and behaviour affected by the adversely perceived performance of housing schemes and entire lower-income neighbourhoods might encourage further deterioration of the cityscape, adversely influencing citizens’ feelings of self-esteem, their social standing in the community, their relationships to neighbours, sense of belonging, and sense of identity with the place, further affecting maintenance of social order, encouragement of self-development and promotion of well-being for the population.

The process of social and spatial differentiation that characterizes the urbanization of Brazilian cities is marked by strong segregation and segmentation of urban space in terms of social groups (Maricato, 2001). Segregation is also derived from a dispute for convenient location within the city. It is a process in which different classes or social strata tend to concentrate more intensively in certain regions or groups of neighbourhoods, sometimes creating a significant concentration of low-income population in large areas. The problem seems to be directly related to characteristics of spatial configuration and location of housing schemes, since segregation can be related to the geometric distance (location) or topological distance (configuration). Marques (2007) points out that segregation means, besides the social separation, inequality of access, which can restrict circulation or hinder the establishment of frequent contact between groups. In this sense, the urban space is inherently unequal; availability of equipment, infrastructure and quality of buildings, as well as the inequality result from differences in accessibility to all points of urban space. In order to account for the attested influence of the built environment on spatial behaviour and well-being, this investigation focuses on the configuration characteristics that affect user attitudes and the perception of environmental image of social housing schemes.

The network of social relationships is regarded as essential to residents’ effective integration in the community they live, and territorial behaviour is part of a system that allows social organisation take place, promoting neighbourhood interaction and community formation. Consequently, legibility of site layout, which results from how the site is organised and how the buildings and spaces are located and related to each other, affect the ways spaces are used (Lay, 1998). That is, despite spatial behaviour or user satisfaction cannot be determined by design, it can establish a number of physical and spatial qualities that can support or inhibit patterns of behaviour, consequently affecting the intensity of contact among residents. The literature on human cognition suggests that configuration aspects of built environments have significant consequences. Lynch (1960) says that legibility, which is highly related to configuration aspects, may play a decisive role in acquiring a sense of spatial control in spatial experience. He notes that, in order to be “imageable”, an area needs to be apprehended as a pattern of high continuity, with a number of distinctive but interconnected parts. Moreover, he argues that in the process of way finding, the strategic link is the environmental image: a generalized mental picture of the exterior physical world, which benefits from architectural legibility as experienced by an individual, further emphasizing affective qualities of spatial form that is central to the emotional and physical well-being of the inhabitant population, personally as well as socially.

Moreover, Golledge and Stimson (1997) emphasize that the path or network structure used in everyday spatial behaviour becomes critical feature of the image of a spatial environment. Others suggest that spatial layout of the built environment influences the accuracy of cognitive representations of real world spatial information (e.g. Appleyard, 1969; O’Neill, 1991). Downs and Stea (1973) note that the process of cognitive mapping is a means of structuring, interpreting and coping with a complex sets of information that exist in different environments: cognitive maps are useful instrument for recovering information about the way we represent the environment, the regularity or irregularity of frameworks such as street systems, and the most salient positive and negative elements, which further denote user attitudes towards that environment.

From a different approach, Hillier (1996) has argued that spatial configuration may face constraints on spatial experience since it appears to encourage or impede aspects of human activity through spatial cognition and subsequent behaviour. Since 1984, Hillier and Hanson set out a theory of space as an aspect of social life, which has developed in the direction of better understanding the spatial nature of buildings and cities through techniques of configuration analysis, such as space syntax analysis tool applications, which allow dealing graphically with the numerical properties of spatial layouts in order to measure accessibility. In simple terms, spatial configuration deals with a set of interdependent relations originated by a network structure in which each part is determined by its relation to all the others. According to Peponis and Wineman (2002), built space can be defined as a field of structured co-presence, co-awareness and encounter. It follows that built space is to be understood as a relational pattern, a pattern of distinctions, separations, interfaces and connections. The theorem chosen by Peponis and Wineman (2002) to illustrate ways in which built space works socially deals with linear spaces, such as streets in urban areas and the paths of movement along those spaces, and argue that high accessibility implies a higher probability that a space will be used for movement. That is, the degree of accessibility and consequently potential of movement and presence of people in the urban space would affect the choice of path to be followed by pedestrians, since people would be attracted by spaces with people and would tend to avoid deserted spaces, as Gehl (1987) points out.

So far, space syntax has contributed sophisticated ways for dealing with urban layouts as differentiated patterns of large-scale connections. This complements the emphasis on local attributes (such as the dimensional profile of street sections, the characterization of boundaries, or the attributes and qualities of individual open spaces) that is typical in many studies of urban space use (e.g. Whyte, 1980). Since Jane Jacobs (1961), the circulation of people and appropriation of public space has been mentioned as a crucial element to the *urban vitality*, as the number of encounters increases potential interactions among users and urban security. In addition, Jacobs claims that certain conditions can also affect interaction, such as *population density*, where higher densities are associated with higher number of interactions; *interface between public and private spaces* that generate permeability, favouring greater movement of people and interaction between them and positively affecting perception of security; *urban diversity* with variety of uses, activities, built form, social classes and lifestyles, coexisting in the same space; and *limited distances* that might increase opportunities for social contact. Then, it is assumed that urban structures and spaces that do not have these conditions can hinder or discourage social interaction among residents and generate segregation, which appears as negative consequence of the lack of social interaction.

Therefore, it is understood that the essential quality of cities is to fulfil the need to provide meeting places and support social exchange and social interaction is considered a key indicator of housing performance, which according to Alexander (1965), is an essential mechanism for the functioning of the city. Authors (e.g. Cooper 1975; Lay, 1998; Basso, 2001; Gambim, 2007) highlight the important role of public open spaces play in residential areas on promoting social interaction and indicate that the open spaces, depending on how they are configured and in accordance with the existent physical elements, can encourage contact between people. It follows the premise that certain urban structures can encourage or discourage the occurrence of more intense social interaction. Complementary, Hillier (1998) argues that, independent of density of a certain area, if the configuration makes the natural movement of pedestrians more difficult, there will not be a sufficient number of people to generate the perception of a well appropriated and used space.

In this context, this study incorporates global configuration aspects and their cognitive dimensions within a single framework in investigating the relationships between man and built environment, more specifically those involving the analysis of relationships between the configuration characteristics of accessibility, legibility and environmental image. It attempts to identify configuration patterns that might be collectively perceived as fulfilling or not residents' satisfaction with the housing scheme and their responses to it through positive or negative

behaviour, and higher or lower social interaction. It is further assumed that good or bad environmental performance of social housing is reflected, among other things, on resident social behaviour and self-esteem, affected by the degree of satisfaction with the place where they live. Finally, it explores the effects of levels of integration of housing schemes on the legibility and imageability of the area and degrees of social interaction among residents and neighbourhoods, in order to produce evidence to base the production of more qualified residential environments that facilitate sociability, promoting sense of belonging and citizenship, all of which support residents' well-being.

Methodology

In order to achieve the objectives of this study, the relationship between housing schemes of different layouts, sizes and location in the city, and the level of interaction among dwellers in the scheme, interaction between the housing scheme and the immediate surroundings and the city, were analyzed. The case study consists of four housing schemes produced by COHAB - Housing Company of the State of Rio Grande do Sul, located in the city of Montenegro, characterized by single-family housing units. The sample of housing schemes was selected based on the axial maps. The housing schemes show different levels of integration in the urban fabric, as measured by the axial map of global and local integration (Figures 1 and 2) and the analysis of street connections with the immediate surroundings. Integration measure is a key global measure in syntactic analysis which relates each space in the settlement with all the others, providing information about accessibility of each one in relation to all other spaces (Hillier, 1996). In the global integration (Figure 1), each street that constitute the housing scheme is analyzed in relation to all the streets of the urban system, whereas in the local integration (Figure 2) each street that constitute the housing scheme is analyzed in relation to a specific number of streets, departing from each of these streets. Therefore, global integration tells about the accessibility of a housing scheme in relation to the city as a whole, while local integration tells more about accessibility in the housing scheme: the shallower the axial line (red and orange lines), the more integrated or accessible is the space. On the other hand, spaces with more depth are the most segregated (green and blue lines: yellow is in between integrated and segregated lines), as they are less accessible in relation to all the other.

Figure 1. Axial map of Montenegro, Global Integration.

Figure 2. Axial map of Montenegro, Local Integration R3.

The schemes are of small size (up to 50 housing units), medium (51 to 200 housing units) and large (more than 201 units) and are differently located in relation to the consolidated urban area of the city (Table 1).

Table 1. Sample of housing schemes

Housing scheme (h.s.)	Number of residential units	Distance in relation to the city	Configuration – integration in the urban fabric
Cinco de Maio	Medium size 172 units	Close to the old city centre	Not integrated
Vila Popular	Medium size 107 units	Close to the old and new city centre	Integrated
Vila São Pedro	Small size 20 units	Close to the new city centre	Integrated
Germano Henck	Large size 366 units	Far from the old and new city centre	Not integrated

The factors most mentioned in the literature that might promote or inhibit social interaction such as characteristics of open public spaces, relations with the surrounding buildings, quality of infrastructure, services, retail and entertainment available, as well as the morphological characteristics of the scheme and the socioeconomic characteristics of dwellers, were investigated.

Methodological procedures consisted of record information, physical survey (use of buildings, vegetation, furniture and equipment in the housing schemes and surroundings) and mental maps with interviews in a sample of 72 interviewees residents of the housing schemes and residents of the surrounding areas (verification of perceived territory). Systematic observations of behaviour registered in 112 behavioural maps and application of 210 questionnaires to residents of the housing scheme and residents of surrounding area, were also carried out in order to measure the degree of social interaction and attitudes among residents in the h.s. and within the neighbourhood. The sample of respondents was defined to fulfil at least 30 residents in the h.s. and 30 residents in the surrounding area, except in Vila São Pedro, with a total of 20 units. The statistical analysis of quantitative data through frequencies and non-

parametric tests such as Kruskal-Wallis and Spearman allowed inferring relationships and correlations between variables. Map of barriers and syntax analysis (Hillier & Hanson, 1984) were further used.

Results

The results focus upon the analysis of relationships between spatial configuration and social interaction, and the verification of the intensity of social interaction among the housing schemes investigated.

Characterization of the housing schemes

Cinco de Maio h.s. was built in 1969 and represents not integrated scheme at local and global levels, medium size and located near the city centre. It has two kindergartens, a school, a community centre and a gymnasium. Despite its steep slopes and lack of equipment, the existing green area in the neighbourhood is used by residents of the h.s. to perform social activities. There are few retail outlets and service in the housing scheme and surroundings (Figures 3 and 4).

Figure 3. Cinco de Maio h.s. and surroundings.

Figure 4. Axial map Cinco de Maio h.s. and surroundings (Global Integration extracted from Fig. 1).

Vila Popular h.s. was implemented in 1968, medium size with 107 single-family housing units. This scheme is integrated to the surroundings, with an integration line of high integration

value in relation to the system, is located close to the city centre and has a green area and a community association.

Figure 5. Vila Popular h.s. and immediate surroundings.

Figure 6. Axial map Vila Popular h.s. and immediate surroundings. (Global Integration extracted from Figure 1).

In the surroundings, there are two schools, a nursery, a religious temple and a recreational space with a football field, and a reduced number of retail outlets and service in the scheme and its surroundings (Figures 5 and 6 above).

Vila São Pedro h.s. was built in 1970, with 20 single-family units. It has a green area and a school. In the surroundings, there are four houses of worship and a parish pavilion, which features group activities and meetings of community associations.

Figure 7. Vila São Pedro h.s. and immediate surroundings.

There are many retail outlets and services, as this area has become a new centre of commerce and city services, that is, the new city centre. The existing shops are located along a street peripheral to the housing development and serve the residents of scheme and also the residents living in the surrounding and in the city (Figures 7 and 8).

Figure 8. Axial map Vila São Pedro h.s. and immediate surroundings. (Global Integration extracted from Figure 1).

Figure 9. Germano Henck h.s. and immediate surroundings.

Figure 10. Axial map Germano Henck h.s. and immediate surroundings. (Global Integration extracted from Figure 1).

Germano Henck h.s. is the largest and most segregated scheme, built in 1984. It has a school, a nursery, two places of worship, and a community centre and a church under construction. In the surroundings, there are health clinic and two places of worship. There are few retail outlets

and services in the neighbourhood, which are located in the most integrated streets, but only serve the residents of the scheme (Figures 9 and 10, below).

Relationship between spatial configuration and social interaction

It was investigated whether the integration of the scheme in the existing urban fabric, due to spatial configuration, helps the residents to integrate into the neighbourhood/city and recognize as belonging to the city. When integrated schemes were analyzed, it was found that Vila São Pedro h.s. (small size) is integrated because it is blended with the existing urban fabric, and Vila Popular h.s. (medium size) is integrated into the environment via a central street that connects neighbourhoods. However, it was verified through the axial maps (Figures 5 and 6) that the small h.s. presents continuity of urban fabric and medium size housing schemes do not, indicating greater homogeneity in the area where the small-size scheme is located.

It was found that Vila São Pedro h.s. (small-size and integrated) is inserted in the neighbourhood boundaries perceived by residents of the scheme and in the surroundings, and variations in perceptions refer to the structural pathways that serve as physical barriers, indicating that the continuity of streets in the surroundings influence the perception of integration. However, in the Vila Popular h.s. (integrated and medium-size), resident perception of neighbourhood boundaries includes only the scheme, possibly because it is a concentrated occupation, facing the main street and with few connections in the existing urban fabric. Furthermore, the perception of boundaries is also related to structural pathways that generate physical barriers. Thus, it was found that the existence of very integrated streets in the system did not influence the perception of integration, and just indicates good accessibility. Behavioural observations confirmed that the green space is heavily used by residents, despite having little equipment and furniture. It also became evident that the proximity between the scheme and the city centre, contributed to a more urban pattern of co-presence and possibilities of interaction.

Meanwhile, in Vila Popular h.s. (mid-size and integrated), behavioural observations underscore the importance of the main road system, the heavy flow of vehicles and pedestrians in different neighbourhoods, confirming researches showing that the degree of integration of a space is strongly correlated with the number of people moving in it. According to Peponis (1992), spatial configuration only determines the potential for others to notice, as the backdrop for an active society, but do not prove that people interact, share and exchange experiences among themselves, or even notice each other. In addition, it was confirmed that open spaces in Vila Popular do not meet the necessary requirements to perform activities of social life, for example, due to narrowing and irregularity of sidewalks, lack of vegetation and shading in the square, making it difficult to stay in the place, reducing opportunities for social and informal contact and negatively influencing the level of interaction among residents.

Results further indicate that residents in Vila São Pedro h.s. (integrated and small) are the most satisfied with where the place they live and the neighbourhood, while residents in Vila Popular (integrated and mid-size) are less satisfied than those from Vila São Pedro, but have better evaluation than the other schemes (not integrated) and the surroundings. Residents in Vila São Pedro also showed better evaluation relationship with neighbours in the scheme and neighbours in the surroundings while Vila Popular appears in third place in the evaluation of quality and intensity of relationship among the residents of the scheme neighbourhood where they live, being superior only to the assessments of residents, probably due to the fact that maximizing the integration increases the control of the strangers in the place, to the detriment of the local control, i.e., the main road with high-value integration enhances the flow of strangers and decreases the control of residents, therefore decreasing opportunities of interaction among the residents. Regarding the relationship in the neighbourhood, residents in integrated mid-size scheme have a better assessment than residents of other non-integrated schemes and surroundings, but with lower assessment than residents in the integrated small-size scheme. It is noteworthy that a significant percentage of respondents of this scheme consider as

“neighbourhood” only the area of the housing scheme. Finally, residents of two integrated schemes and respective surroundings are among those who reported having more friends in the place where they live, however, also indicate a high percentage of friends outside the neighbourhood, showing interaction with residents in the scheme, in the immediate surroundings and the city. The results suggest that the integration of the scheme with the existing urban context, due to spatial configuration, helps the residents to integrate into the neighbourhood/city and to become recognized as belonging to the city as well as with satisfaction with where they live. However, it appears that the perception of integration of the scheme is more related to the continuity of streets of the scheme in the vicinity, than the existence of more integrated streets in the system.

Intensity of social interaction among housing schemes

Vila São Pedro h.s. is inserted into an existing subdivision and therefore within the existing urban fabric. The continuity of the urban fabric indicates a homogeneous area. Through interviews and mental maps, it was found that the dwelling units in the scheme are perceived as part of the neighbourhood in which they inserted, both by residents in the h.s. and by residents in the surroundings. The behavioural observations indicate that the green area is heavily used by residents of all age groups, despite not having sitting facilities along the sidewalks, which facilitates social interaction among residents of the scheme and immediate surroundings. It was also noted that the sidewalks, due to inadequate width and maintenance, are not used for passive activities or socialization. Besides, the proximity of the h.s to the new city centre generates great flow of pedestrians and vehicles, contributing positively to residents’ satisfaction with where they live and with the neighbourhood. There was a continuity in the flow of pedestrians on the streets of the settlement, due to the existence of services used on a daily basis (possibility of movement on foot), giving a more urban pattern of co-presence and possibility of interaction, which tends to be influenced by the geometric distance (Holanda, 2002). When comparing all schemes, results indicate that residents living in Vila São Pedro are the most satisfied with where they live and with the neighbourhood. They also had a better assessment than the others h.s. of relationships among residents where they live and in the neighbourhood, besides presenting a high percentage of friends outside the neighbourhood, showing interaction not only with the residents of the scheme, but also with the immediate surroundings and the city (Table 2).

Table 2. Intensity of friendship among residents

	Cinco de Maio		Vila Popular		São Pedro		Germano	
	scheme	surrounding	scheme	surrounding	scheme	surrounding	scheme	surrounding
	30	24	30	24	20	31	40	11
	(100%)	(100%)	(100%)	(100%)	(100%)	(100%)	(100%)	(100%)
+ friends in the h.s.	19	7	15	13	8	15	27	5
	(63,3)	(29,2)	(50,0)	(54,2)	(40,0)	(48,4)	(67,5)	(45,5)
+ friends in the neighbourhood	0	2	1	0	1	3	1	0
	(0,0)	(8,3)	(3,3)	(0,0)	(5,0)	(9,7)	(2,5)	(0,0)
+ friends outside the neighbourhood	11	8	11	8	7	8	8	3
	(36,7)	(33,3)	(36,7)	(33,3)	(35,0)	(25,8)	(20,0)	(27,3)
equal	0	7	3	3	4	5	4	3
	(0,0)	(29,2)	(10,0)	(12,5)	(20,0)	(16,1)	(10,0)	(27,3)

The analyzed data allowed to verify that the size of the housing scheme may influence the degree of social interaction with residents of the immediate surroundings, where the smaller the number of units of the set, the greater the degree of social interaction with residents of the

immediate surroundings. However, it is important to note that the h.s. investigated, in addition to its small size, is characterized by being integrated and well located near a commercial centre, which can influence the results, i.e., a segregated small-size scheme could provide different results. Moreover, it was investigated whether the most segregated housing scheme Germano Henck, located far from consolidated urban areas present higher interaction among residents of the scheme than the more integrated housing developments located in central areas. It was found through the mental maps that residents of the scheme consider as part of the scheme just the occupation on the south part of the main road, possibly because it is concentrated, segregated from the surroundings (connected at only one point), with well defined limits and the presence of the road, which seems to work as a physical barrier. It was confirmed that the deeper the system (low integration) more difficult is appropriation by the pedestrian, particularly by strangers to the place that, in general, are most people in public spaces (Holanda, 2002). It was possible to identify through the interviews the existence of 'social cohesion', as residents point out that everyone knows everyone, are protected and feel safe ('nothing happens with the people here').

Through questionnaires, it was verified that residents in this large scheme have one of the best assessments in relation to satisfaction with security, indicating the existence of territorial control and internal cohesion. Besides, behavioural observations confirm that the green area, soccer field and pedestrian crossings are heavily used by children, young adults and elderly, facilitating social interaction among residents, despite the lack of equipment and furniture. It was further observed that the pedestrian flow starts from the bus stop at the entrance of the scheme, since the shift to the city centre happens basically by bus. The continuous flow of pedestrians contributes to a more urban pattern of co-presence and possibility of interaction among residents. This scheme has the highest percentage of residents who have more friends in the place where they live. However, it was not found a positive assessment higher than in the other schemes that might indicate a better relationship or a stronger relationship among the residents in Germano Henck. Nonetheless, it must be pointed out that due to its location, far from consolidated urban areas, outsiders do not penetrate in the inner parts of the place, which indicates the existence of friendships restricted to the place where they live, confirming that schemes more distant and isolated can cause residents to relate only to each other and encourage social segregation in relation to the city.

Conclusion

Results indicate that the level of integration of the housing scheme in the pre-existing urban fabric, due to its spatial configuration, can help residents to integrate into the neighbourhood/city and feel recognized as belonging to the city. It was noted that residents in integrated schemes tend to be the most satisfied with where they live and socially interact more intensively with residents in the housing scheme, with residents of the immediate surroundings and with the city. In this sense, spatial configuration seems to be the variable with more direct influence on social interaction among residents, confirming Hillier and Hanson's (1984) results, that put accessibility as the most effective component in the dynamics of segregation, as stated by the social distance through the natural implication of movement networks. According to the authors, from the urban structure and dynamics of social classes' point of view, segregated areas would be used by relatively homogeneous populations and morphology of these housing areas could show these pre-determinations, as well as the contrast of juxtapositions of segregated areas. Nonetheless, when compared to larger housing schemes, smaller schemes tend to have better assessment regarding the relationship among residents in the place where they live and with neighbours in the surrounding area. That is, those residents develop friendships in and outside the neighbourhood, and at the city scale, as a result of higher accessibility. It is worth noting that smaller schemes require smaller areas for implementation and can be easily inserted

into the existing urban fabric, with better location and closer to local services, which can positively affect residents' satisfaction with where they live and the neighbourhood.

It was further confirmed that housing schemes located distant from the consolidated urban area, usually of large size, tend to prevent strangers to naturally penetrate to the inner parts of the scheme, thereby maximizing local control and friendship among residents and reducing opportunities of interaction with outsiders. On the other hand, the small size and good location of social housing schemes can not be a sufficient condition for the integration of residents together with the surroundings and the city, as spatial configuration seem to be more crucial. However, it is important to note that although there is a common sense that certain characteristics are more favourable to the performance of housing schemes for the effects on social interaction, there are no conclusive studies. Finally, this study highlights the importance of assessing the effects of spatial configuration in order to produce more integrated and qualified residential environments that support and facilitate social interaction among residents, promoting a sense of belonging and citizenship, further confirming that the architecture of settlements can positively influence our physical, social and emotional health.

Characterization of the relationship between commercial plots and building patterns: a general survey in urban area of Nanjing, China

Jingjing Jiang

School of Architecture and Urban Planning, Nanjing University. Hankou Road 22, Nanjing, 210093 Nanjing, Jiangsu, P. R. China. E-mail: jingjingjiang0919@gmail.com

Abstract. *Following Conzenian tradition of urban morphology, several studies have explored characteristics of commercial plots in China in a framework identifying the fundamental elements of urban form: Streets, plots and buildings. However, previous researches lack exploration on the relationship between building patterns and plots, without taking the complex controlling factors of commercial plots into account. Therefore, interdisciplinary approach must be applied to explain the formation rules of building patterns. Building typology and planar geometry rules as typomorphological base must be applied into the characterization of public plots. In this paper all the 645 commercial plots along the main roads in Nanjing are grouped into a hierarchically structured category according to plot shape and building outline. It focuses on two morphological criterions: the shape similarity and positional relationship between plots and buildings; and demonstrates how these correlates to plot coverage ratio and arrangement of open space. Such knowledge of rules can support subsequent urban analysis, planning, and guide future design of commercial plots.*

Key Words: Commercial plot, building outline, coverage ratio, positional relationship

Introduction

Public buildings in China have undergone a rapid development in the last 60 years. Since the different functions of sites within an urban area tend to be differentiated by physical form, each morphological category tends to have distinctive form and therefore can be studied individually (Whitehand, 2009; Abramson, 2008). However, commercial plots in urban area are under control of especially complicated conditions both from land use indicators and boundary conditions. The public buildings within commercial plots are required to meet the demand of public activities and an elaborate organization of the internal pedestrian and car circulation. With the pursuit of becoming a landmark, public buildings in China especially the high-rise mixed-use buildings show a great diversity of building forms.

Controversies have existed for long whether the architectural arrangement of public plots follows certain common rules, regardless of the functions of the buildings. Since the modern public building design have for long been use-led design codes, rather than form-led principles.

However, from the architecture designer's perspective, even under the seemingly disordered situation lack of form control, there seems to be certain rules restricting a 'design envelope', that is to say, the suitable buildable area for the public building within the plot, such as the circulation inside the plot, the surrounding traffic condition, the intention of creation of public spaces within the site, etc. These rules on site plan control bring certain similarities to the architectural arrangement within the commercial plots, regardless of the function or contents of the buildings. The difficulty of research lies in which morphological criterion to choose, in order to evaluate and illustrate the underlying rules in building arrangement of commercial plots.

This paper is based on a general survey of all the 645 commercial plots in Nanjing and proposes several morphological indicators in description and prescription of the morphological relationship between commercial plots and buildings inside.

Research Background

The combination of hierarchical framework of urban morphology and building typology

Within urban morphology there is general consensus on the core, fundamental elements of physical built form: streets, plots and buildings, following the tradition of Conzenian school. On the other hand, the Italian school established by Muratori and further developed by Cannigia focuses on mainly on the architectural typology research.

The understanding of urban morphology and the evolution of building typologies are keys to the zoning and design nowadays. Several scholars have tried to combine the two theories together to provide an efficient way to evaluate the morphological characteristic of urban tissue and to guide the zoning and design of urban area. Based on the work of Conzen and Caniggia, Kropf proposed a framework combining building typology and urban morphology and illustrate an example of the application of typomorphological principles (Kropf, 1998).

The selection of assessment criteria in morphological description on the plot level

Several previous studies on plots and buildings provided inspiring research framework and criterions for assessment of the morphological relationship between street, commercial plots and buildings within the plots.

The shape Grammar theory (M.Tapia, 1999) describes shapes and compositional logics by simplifying the spatial elements such as plot edge, building, open space as well as access into basic components of a relative network, in which way topological relationships of the morphological elements are revealed and described. Through implement of the shape grammar rules space structure of certain area is revealed.

Following the conzenian tradition, the assessment methodology named morpho (Oliveira, 2013) proposed by Vitor Oliveira provide a quantitative framework to assess the fundamental elements of urban form at different scales, that is to say, streets, plots, and buildings, and each relation between the pairs of element. He chose several morphological criteria such as ratio of building height to street width and alignment of buildings as well as dimensions of street blocks to evaluate the morphological characteristics of a given area quantitatively.

The addition of geometry rules in morphological description on the plot level

The plots as study objects in former studies on plot characteristics are usually of square or rectangular form lying in a regular order. However, the forms of blocks and plots in China are much more complicated with various shapes and sizes. Besides, the assessment of the positional relationship between building and plot must be based on the recognition of plots and building outlines as geometrical units. Therefore, planar geometry rules for necessary simplification of the plot shapes and building outlines must be applied in the study (Stiny, 2011).

This paper combines the methods above following the hierarchical framework of assessment between streets, plots and buildings and mainly focuses on the discussion of morphological relationship between commercial plots and public buildings inside by evaluating the shape similarity and positional relationship between plot and building.

The general description of the commercial plots in Nanjing

Nanjing is the capital city of Jiangsu Province, which situates in the more developed eastern region of China, with a population of more than 8.16 million, and a total area of 6597 square kilometers. Public plots in Nanjing have undergone complex transformation due to the change in land ownership in the past decades. The public buildings in Nanjing represent a very broad category which includes the buildings of different purpose and contents.

In total, there are 862 commercial plots among the main roads and secondary main roads in Nanjing, which account for 75% of all the commercial plots in Nanjing. The selection of research objects is according to the rules as follow, in order to clarify the basic condition and to avoid certain unnecessary exceptional cases along branch roads. Plots under construction or without constructional development are excluded; Shops along the streets, which are mostly extensions affiliated to residential buildings, are excluded; commercial plots, which are used as temporary garages are excluded; historical buildings which are now in public use, are excluded, because they don't follow the modern design principles.

Therefore, 645 commercial plots with the land use of office buildings, hotel buildings, and shopping malls or mixed use of the mentioned functions are chosen as the analysis database among all the plots.

The sizes of commercial plots varies dramatically from 131 m² to 248314 m². Above all, the most of the plots have a total area at the level of 5000 m². Generally, the size of the hotel plots are the smallest.

Six types of plot shapes

The shapes of the plots are categorized into six types according to geometrical rules: Square form rectangular form, triangle form, L shape, Z shape and U shape. The last three types are transformed from the square form or rectangular form due to the several plot property transitions during the last decades of land use change.

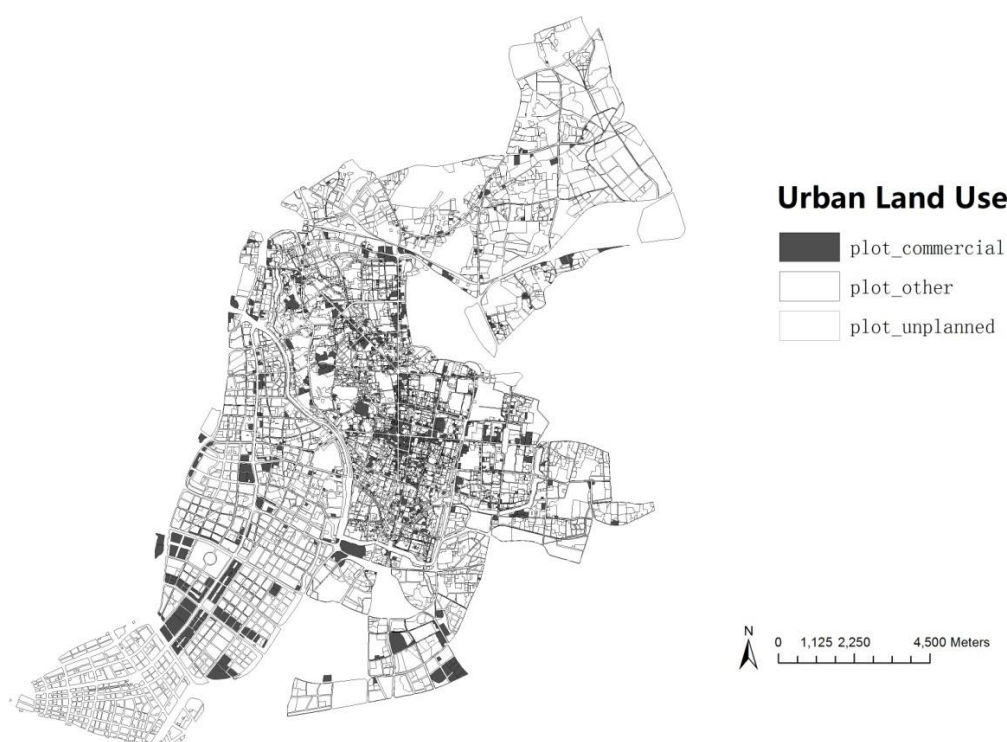

Figure1. The distribution of commercial plots all over Nanjing.

Figure 2. The 6 types of plot shapes.

At the street level: the boundary conditions of the commercial plots

Plot boundary conditions contribute a lot to the pedestrian flow and car circulation organization within the plot. The study of plot boundary firstly focuses on the plot boundaries, which are adjacent to highest-ranking roads.

The road network in Nanjing is a hierarchy system, composed of the main roads, the secondary main roads, and the branch roads. Blocks are divided by main roads and secondary main roads. Semi-blocks are divided by branch roads within the blocks. Due to the complex natural conditions (rivers, mountains) and several morphological transformation of the street system, the blocks of Nanjing varies significantly in block size, and proportion, which brings variable boundary condition to the plots inside (Zhang, 2013).

Figure 3. The existing boundary condition of commercial plots.

At the street level: Assessment of the relationship between Street and building:

Since the plot boundary adjacent to streets is parallel to streets, and the plot boundary is usually 4.5 meters setback from the street edge, the distance of building setback from main streets can be evaluated by the setback distance from building outline to the plot edge adjacent to highest-ranking road.

The setback distance of buildings from the plot boundary adjacent to the main roads (secondary main roads) vary dramatically from 0m to 120m.

As we can see from the statistics, the setback distances of buildings from the main streets in the Hexi (new city) area are averagely larger from those in the main city area of Nanjing.

This situation indicates, that the urban tissue formed by public buildings has a fragmented boundaries to the streets. This is due to the lack of urban planning code of the setback distance of building layout to the streets.

Figure 4. The building setback distance from the highest-ranking road.

Further comparison of four commercial districts in Nanjing

Four public districts situated in four part of Nanjing are chosen for closer study of the relationship between streets and commercial plots.

Figure 5. Four commercial districts in Nanjing.

Tissue I: Continuous frontages of public buildings in Xinjiekou CBD district which lies in the central of old city, which has the highest density of commercial plots in Nanjing, with 31 commercial plots inside. The commercial plots are mostly shopping malls and mixed use

buildings. The plots in Xinjiekou CBD are mostly of fragmented shapes like L, Z, or triangle shape. This phenomenon is due to the several phases of morphological transformation of the street structure in different period of time (zhang, 2013). The shape of the plots then accommodate to two road systems in two unparallel coordinate system, one of which is closely related to the ancient water system (about 24 degree to the east of north), the other of which is mainly determined upon the Zhonshan Avenue system completed by 1937 following the design principle of straightness.(zhang, 2013) More than that, the several phases of plot development also contribute to the fragmented plot shapes due to the change of plot ownerships. Adjacent plots appear to be interlocking while the plot are redivided and integrated with morphological information of the former land owners remains in the plots.

Tissue II: Continuous public building frontages and plots in Shanxilu CBD. This area serves as a sub-commercial -center of Nanjing, with 33 public buildings including theaters, shopping malls, commercial office buildings and governmental buildings.

Tissue III: Isolated public buildings in the Zhongyangmen CBD lies in the north fringe part of Nanjing. The district serves as a sub-commercial-center with agglomerated shopping malls and high-rise hotel buildings. The total area of the 15 shopping mall plots vary from 2679m² to 43191m², showing great discrepancy of plot sizes.

Tissue IV: Isolated public buildings in the Hexi CBD district locates in the new town of Nanjing, which is planned as the future administration center of Nanjing. The development of the Hexi CBD started from 2002, controlled thoroughly by the modern planning principles of average block grids. The plots are mainly used for Headquarters of state-owned companies, governmental buildings, and commercial office buildings. The district consists of 11 commercial plots whose total area range from 10667m² to 49456m².

Most of the plots are perpendicular to the streets. The examination of locations of the plots within the block indicates the adjacency condition of plots to main roads. Other boundaries of the plots are adjacent to branch roads or other plots. In the old city area of Nanjing, most of the commercial plots locate along the edge of the blocks, with one boundary adjacent to the main road or secondary main road. In addition, several commercial plots occupy one corner of the block. In the New town (Hexi) area of Nanjing, commercial plots often occupies the whole block, while in the fringe area of Nanjing, the commercial plots often occupies three edges of its block. In certain areas in the Zhongyangmen district in the north fringe part of Nanjing, the main roads (secondary main roads) exist also on the opposite side of the plot.

According to the above analysis, the main morphological distinctions of the commercial plots in different areas exist in three aspects: size, shape and boundary condition.

The assessment of morphological relationship between plot and building

The simplification of building outline and plot shape

To simplify the morphological relationship between the plot and the building, this paper focuses on the planar outline of the building, regardless of the spatial compositions of the building forms, neither the internal spatial arrangement. Slight variations of quadrilateral shape like the bays or short hangouts are ignored in the study.

Simplification rules of building outline and plot shape: The length-width ratio of the building outline and that of the plot is considered as the main factor to distinguish whether it is a square or a rectangular. Since the extremely high length-to width ratio of a plot can lead to different design strategies in building arrangement compared to the square plots with even length and width. When the two adjacent boundaries are slightly not perpendicular, they are considered perpendicular.

Figure 6. Examples of Simplification Rules of the Shapes.

The similarity and non-similarity between plot shape and building outline

According to the above principles of shape simplification, the plots shapes are simplified into two main categories: the quadrilateral plots and the deformed quadrilateral plots. The quadrilateral category is subdivided into two types: square plot with a length-width ratio from 1/1 to 2/1; rectangular plot with a length-width ratio larger than 2/1. The deformed quadrilateral category consists of three plot types: L-shape plots with one corner encroached; U shape plots with middle part encroached; Z-shape plots with two corners on the diagonal encroached.

The building outlines are classified into six types: square shape, rectangular, L shape, U shape with a half surrounded open space in the center, Z shape with two corners on the diagonal encroached, multiple separate buildings in one plot.

Figure 7. Plots with similar-shape building outlines and plots with non-similar-shape building outlines.

Figure 8 (left). Amount of building outline types within plots.

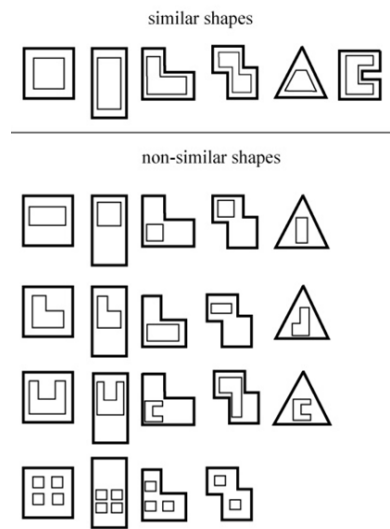

Figure 9. All existing shape relationship between plots and buildings.

Morphological relationships between plot shape and building outline are further classified into two types: similar shapes and non-similar shapes. All the existing morphological relationship types are listed in sequence according to the coverage ratio of the certain plot.

Firstly, 90% of all the 645 commercial plots have one single building inside the plot. Therefore, this paper mainly discusses the single-building plots.

Statistics show that there are 136 square building outlines in square plots, 135 rectangular building outlines in rectangular plots, and 79 L-shape building outlines in L-shape plots. Consequently it can be concluded, that those plots, within which the buildings have similar shape with its plot shape, play a dominant role among all the commercial plots.

However, as a matter of fact, many factors of a broad range from land use indicators to plot boundaries conditions as well as internal spatial arrangement are responsible to the architectural composition of commercial plots. In this way, it is dubious to assert that the building outline within the commercial plot is controlled by the plot shape. Further study on the relative plot indicators is required to explore the underlying factors which control dominantly the morphological relationship between plot and building pattern. Through the examination of several land use indicators, plot coverage ratio stands out as a dominant factor affecting building pattern.

Comparison of plot coverage ratio and building-plot shape similarity

The coverage ratios of all the commercial plots differ remarkably from 0.04 to 1, and the majority of the plot coverage ratio lies in the range from 0.2 to 0.9.

Figure 10.The shape similarity and plot coverage ratio.

Despite four square plots of high coverage with L-shape building outline inside, all of the commercial plots with a coverage ratio of over 0.68 have similar building outline with the plot shape. For plots with coverage ratio from 0.20 to 0.67, there is no obvious rule for whether the building outlines have similar shape relation with the plot or not. For plots with a coverage ratio less than 0.19 the buildings outlines inside are all non-similar to the plots.

It can be concluded that when a plot has a coverage ratio of over 0.68, the building outline usually duplicate the plot shape.

Besides the shape relationship between the building outline and the plot, another important morphological factor is the position of the building within the plot. The urban tissue formed by commercial plots is significantly influenced by whether the adjacent plots share a consistent and continuous building setting, in which way a continuous or a disordered frontage is formed.

Assessment of building position within the plot

The void space in the plot can be used to evaluate the position of building. Since the building outlines are generally parallel to the adjacent plot boundary, the position of the building inside the plot can be described by measuring the setback distance of each building edge to the adjacent plot boundary.

The setback distance of building within the plot can be divided into kinds of uses: one is linear space for traffic; the other is open space mainly for static activities.

1.0m There is no void space between the building edge and the adjacent plot boundary.

2.1-3m. The aisle between the plot boundary and building edge is designed mainly for necessary pedestrian access.

3.4-6m. The path is left for fire engine access, which follows the design code for public buildings. The 4-meter paths also serve as the car path inside the plot.

4.10 meters and more. The open space usually has three uses: pedestrian open plaza, parking lot, landscape area, or the combination of the mentioned functions.

Figure 11. Existing setback distance with function.

Therefore, building positions can be classified into two types: overlapping centroids of plot shape and building outline, non-overlapping centroids of plot and building outline.

When the centroid of the building outline overlaps that of the plot shape, there exist two circumstances: the setback distances of each edge of the building outline are equally the same; or the opposite setback distances of the building outline are the same.

When the centroid of the building outline does not overlap that of the plot shape, it indicates that each access between the building and the plot boundary are not equal and are of different uses.

The plots with similar-shape building outline are simplified into quadrilateral within quadrilateral prototypes with various positional relationships. The plots with non-similar-shape

building outline are simplified into quadrilateral with an addition of void space of different position within the quadrilateral plots.

Based on the careful examination of all the 645 commercial plots, the building position are classified into the following table according to the setback distance of each building edge from the plot boundary. The table is classified into two main categories: plots without open squares and plots with open areas.

no open square					with open square											
no setback	1 setback	2 setbacks	3 setbacks	4 setbacks	1 setback	2 setbacks	3 setbacks	4 setbacks	partial square							

Figure12. All the existing building positional type within the plot

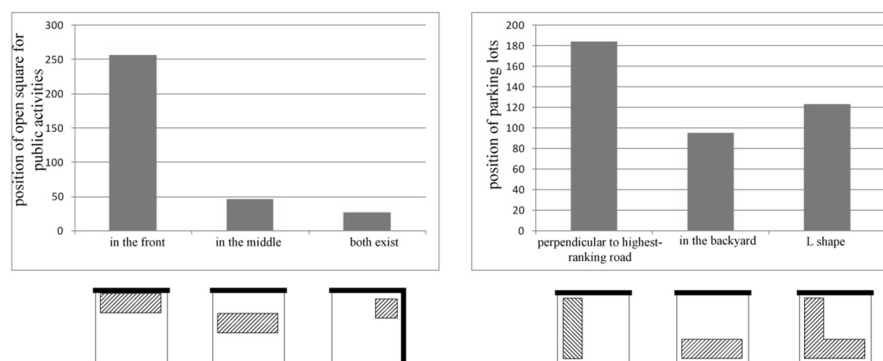

Figure 13. Types of open squares for public activities and parking lots in different location within plot.

Among all the plots with an open square, the most frequently existing positional relationship between plot and building outline are as follows:

Figure14. Seven most frequent existing positional relation types of plot and building.

The position of the open space within the plot plays an important role in controlling the urban tissue which the commercial plots form together. Statistic of all the existing building position type within the plot shows several rules of internal arrangement:

i) for the plots along the edge of the block, the open squares for public activities mainly exist in the front part of the plot parallel to the highest-ranking road. For the plots on the corner of the block, open squares for public activities usually prefer to locate adjacent to the corner of the highest-ranking roads;

ii) parking areas usually locate perpendicular to the highest-road or lie in the backyard of the plot. Sometimes the parking lot exists as an L-shape area continuing from the perpendicular area of the plot to the backyard. Generally the parking lots in the back of the plot have a larger size.

Conclusion and discussion

Based on a general study of all the 645 commercial plots in Nanjing, the study aims at exploring the underlying formation rules of the urban tissue formed by commercial plots. After a series of assessment of the relationship between streets and plots as well as streets and buildings, the study finally focused on the morphological relationship between plot shape and building outline with two assessment criteria: shape similarity between plot and building and building position within the plot.

Firstly, the plot shapes in different areas of Nanjing present to be discrepant. The commercial plots in the old city of Nanjing are usually fragmented due to the several transformation of street system and interlocking to each other. In contrast, the plots in new town and fringe area of Nanjing generally have more complete shapes like squares or rectangles.

Secondly, statistics show that the level of the plot coverage ratio plays a significant part in the rules of the building arrangement within the commercial plots. For plots with a coverage ratio over 70%, the outline of the building usually follows the shape of its plot. For plots with a coverage ratio of less than 70%, there seems to be no dominant rules of building outline. Furthermore, the positional relationship between building and plot is carefully classified. Four types of setback distance indicate the different functions of the void space in the plot. The setback distance is mainly decided by the location of the open space for public activities and car circulation inside the plot.

In the end, the study on the commercial plots in Nanjing proves that interdisciplinary rules must be applied in studying the commercial plots and the modern buildings within them. Knowledge of architectural typology and planar geometry are indispensable in exploring the underlying rules controlling the building arrangement within commercial plots. Other relevant factors such as floor area ratio, building height, as well as building function must be further investigated.

It is worth noting that with the development of construction techniques, there exist more buildings with stilt floor of large area. The above covered area can also serve as pedestrian plaza or parking lot, in which way the simplification of the building outline in this paper is no longer

applicable. Further studies on the stilt floored buildings are required to accommodate the ever-developing topology of modern public architecture.

Municipal average building capacity: a strategic instrument for economic and financial sustainability of urban developments

Emília Malcata Rebelo

Universidade do Porto, Faculdade de Engenharia, Rua Dr. Roberto Frias, s/ n, 4200-465 PORTO, Portugal. CITTA – Research Centre for Territory, Transports and Environment. E-mail: emalcata@fe.up.pt.

Abstract. *The main goal of this research consists in the development of a methodology – based on territorial plans and urban morphologies - that supports the computation of how much average gross built surface is allowed in each municipality. It fits into the overall scope of the revision of the juridical regime of Territorial Management Instruments currently taking place in Portugal, in the wake of the approval of the new Portuguese Basis Law of Land Policy, Territorial Ordering and Urbanism. The assessment of building capacity herein proposed supports the application of current territorial management instruments (such as the Municipal Urbanization Tax) or new instruments - based on a fiscal monitoring over urban developments - in a clear, accurate and objective way. It, thus, enables the implementation of the most innovative goals of this new Basis Law: raising equity and social cohesion, and ensuring that urban development processes are sustainable from an economic and financial perspective. The methodology to compute the average municipal building capacity is applied, as a case study, to the municipality of Ourém, considering the classification of spaces and the urban indexes settled in Ourém's Municipal Master Plan, in Fátima's Urban Development Plan, and in the Detail Plans currently enforced. It can be concluded that urban morphologies that derive from territorial plans support the design of new management instruments in order to: (i) strengthen municipal finance, ensuring municipalities' economic and financial sustainability; (ii) assess, in a clear and objective way, the concrete building capacity of certain urban operations as compared with the municipal average building capacity; (iii) quantify the concrete values that can possibly be collected through current or innovative urban management tools; and (iv) warrant a better equity in the distribution of benefits and charges that accrue from urban development processes.*

Key Words: *economic and financial sustainability, territorial management instruments, equity, building capacity, urban indexes.*

Introduction

All the legislation concerning land, territorial ordering and urban development is currently underway in Portugal. The new Portuguese Basis Law of Land Policy, Territorial Ordering and Urbanism was already approved (Proposta de Lei nº 183/XII, 2014), linked together with the revision of the juridical regime of Territorial Management Instruments, the juridical regime of Urbanization and Edification, and the new Cadastral Law. This is a deep amendment that intends to surmount some drawbacks and contradictions that accrued from the previous legislation, on the one hand, and to contribute to the structural reform of the state in these matters, on the other. In fact, the previously enforced legislation revealed hard to apply and often contradictory especially due to different complex plans that overlapped on the same territories (that had adverse effects on the clearness of applicable rules), the existence of several territorial plans and urban development models specific to each municipality (that hampered integrated development and sustainable articulation among municipalities), and a planning model founded on urban sprawl (that was unable to stop the quick proliferation of vacant land).

Thus this revision involves the reassessment of the core paradigms that underlie land planning and management, territorial ordering, and urban development processes. The new

launched paradigm founds on three basic guidelines: planning increased flexibility; Municipal Master Plan's strengthening as a strategic tool; and a bet on urban rehabilitation to favour town development. One of the core innovative goals of this new paradigm sets that urban plans and programs should include an economic and financial sustainability model. This means that they should only be approved if they are able to engender incomes equal or higher than the charges they will involve. As a result, this model will also provide the achievement of all the other goals this new paradigm settles, namely the linked integration of territorial policies, the efficiency of plan execution devices, the economic and financial sustainability of urban development processes, and the promotion of social cohesion and equity.

The research reported in this article proposes a methodology to compute how much abstract average gross built surface/m² is allowed in each municipality, according to the enforced territorial plans (that is to say, according to the parameters settled in the Municipal Master Plan, Urban Development Plans, Detail Plans, parcelling out procedures, or other territorial management instruments). It is applied, as a case study, to the municipality of Ourém.

The measurement of the abstract average gross built surface/m² is a required condition for a more efficient application of a set of already existent territorial management instruments (such as Municipal Development Charges, that can anyway be reformulated) and newly proposed ones (so to ensure that surplus values engendered by plans, planning decisions and/or public investments should be reassigned to social purposes). It supports the search for more objective and clear urban parameters that underlie municipal decisions and their succeeding implementation that ensure: the economic and financial sustainability of territorial planning and urban developments; the fair collection of part of the land surplus values arising from planning decisions; the clarification of funds' origins and investments aimed at urban development; and a better fair distribution of benefits and charges arising from urban development within each municipality and among different municipalities.

This article finally debates the importance of the average gross built surface/m² for municipalities proper - founded on this new paradigm of territorial planning economic and financial sustainability - to enhance sustainable development and people's quality of life.

Computation of the abstract municipal average gross built surface/m²

Methodology

It is herein proposed the measurement of the municipal average abstract gross built surface/m² according to the urban parameters settled by the territorial plans enforced in a certain municipality, weighed by respective land surfaces (Figure 1).

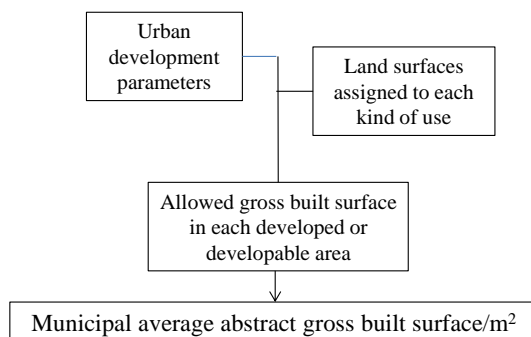

Figure 1. Systematization of the data required to compute the municipal abstract average gross built surface/m².

The municipal average abstract gross built surface/m² represents the gross surface (expressed in m²) allowed by the enforced territorial planning instruments in a certain area. It is computed through the quotient between the sum total of the surfaces where urban parameters of different planning tools apply, multiplied by respective occupation indexes (quotient between the implanted surface and the land surface, expressed in %) and land use indexes (quotient between the total gross built surface and land surface, expressed in m² per m² of land), weighed by the percentage assigned to each type of use, and the total municipality's buildable area.

Case study

Brief characterization of the municipality of Ourém

The municipality of Ourém locates in the Portuguese central region, in the district of Santarém. It is bound in the east by the municipalities of Ferreira do Zêzere and Tomar, in the southeast by Torres Novas, in the south by Alcanena, in the west by the municipalities of Leiria and Batalha, and in the north by Pombal and Alvaiázere. It spans a surface of about 417 km², is made up by 18 parishes, and has a population density of 98,2 inhabitants/km² (www.infopedia.pt) (Figure 2).

Figure 2. Map of the municipality of Ourém with respective parishes.
(Source: <https://www.google.pt/>)

Territorial planning instruments enforced in the municipality of Ourém

The Municipal Master Plan of Ourém²⁰⁰ is the legal planning instrument that frames the urban development activities in this municipality, and that guides the applicable Urban Development Plans and Detail Plans (Article 6th, Urban hierarchy). In the absence of Urban Development Plans, Detail Plans and municipal regulations worked out according to the main guidelines of the Municipal Master Plan for the planning and management operational units, only the precepts

²⁰⁰ The Municipal Master Plan of Ourém was approved by the Resolução do Conselho de Ministros n.º 148-A/2002. This plan was ratified on the 12th March of 2009 (Aviso n.º 5416/2009), and later on, in the 15th October 2009 (Aviso n.º 18200/2009), being afterwards adjusted to the Regional Plan of Territorial Ordering of West and Tagus Valley – PROTOVT (Aviso n.º 11779/2010, ratified by the Declaração de Retificação n.º 1614/2010, of 12th August), and changed on the 29th March 2011 (Aviso n.º 7841/2011). On the 9th April 2013 a modification was enforced in the plan for Pias Longas site (Aviso n.º 4800/2013), which involved a change in the National Environmental Reserve map of Ourém (Aviso n.º 4735/2013).

of the latter are applicable, as well as the statements settled in additional municipal regulations (Article 7th, Supplementary application).

According to Article 8th (Enforced planning instruments) of this same plan, inside the urban perimeter of Fátima applies the respective Urban Development Plan²⁰¹; and in some areas inside the urban perimeter of Ourém apply the enforced Detail Plans.

After the passing of the Urban Development Plan of Fátima, two Detail Plans were enforced inside its urban perimeter, becoming applicable their urban parameters instead of those from the Urban Development Plan: Detail Plan of Avenida Papa João XXIII (Aviso n.º 15622/2009); Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado (Portaria n.º 67/99).

The Detail Plans enforced inside the urban perimeter of Ourém are: Detail Plan of the industrial area of Casal dos Frades (Despacho n.º 195/91); Detail Plan of the Health Centre of Ourém (Portaria n.º 190/97); Detail Plan of Caridade (Portaria n.º 496/93; Portaria n.º 445/97; Declaração n.º 376/99); Detail Plan of Quinta do Ribeirinho (Resolução do Conselho de Ministros n.º 159/2000).

Regulation of land use in the municipality of Ourém

In the regulation of the Municipal Master Plan of Ourém - Chapter III, concerning land uses, Article 33rd (Classes of spaces) - spaces are classified according to their land occupation, use and land use changes, within the following classes²⁰²: urban spaces; developable urban spaces; tourism; industry; extractive industry; equipment; agricultural; forest; agricultural-forest mixed uses; natural; canal-spaces and infrastructures.

In the same article (point 3.) urban perimeters are pointed out as including urban spaces, developable urban spaces, and industrial spaces, according to the delimitating borders settled in the ordering plan.

Article 35th (Urban hierarchy network) settles tree levels for built-up urban areas belonging to the municipality of Ourém, according to the functions anticipated for each one (they may eventually include sets of close built-up urban areas) (Table 1): Level 1 encompasses built-up urban areas with trade, services and equipment functions at municipality and above municipality grounds; Level 2 includes built-up urban areas or sets of areas with trade, services and equipment functions at local grounds; Level 3 comprises the remaining built-up areas or sets of areas.

Section I of chapter III of the Municipal Master Plan of Ourém lays down the rules for the use of urban spaces. Article 36th (Scope and main goal) features the urban spaces (demarcated in the ordering plan) as made up by the existing built urban knitwear provided with urban infrastructure, equipment and services. These spaces are predominantly aimed at housing, despite including other uses, such as tertiary activities, industry, agriculture or tourism, provided they hold housing-compatible characteristics.

Consolidated urban spaces (point 4. of the same article) rank, by their turn, into level 1, 2, or 3 subcategories of urban spaces.

As aforementioned, the urban perimeters of Ourém and Fátima correspond to level 1 built-up urban areas (article 39th, urban built-up areas of Ourém and Fátima). This article further states that rules laid down in articles 40th and 41st should be applied in Ourém and/or Fátima in the absence of Urban Development Plans or Detail Plans inside respective urban perimeters, considering: As medium-density urban spaces the wholly infrastructured urban areas where

²⁰¹ Portaria n.º 633/95, on 21st June, which revision was approved by the Resolução do Conselho de Ministros n.º 148-B/2002 of 30/12; this plan underwent, after its approval, a simplified change on 30/01/2009 (Aviso n.º 2766/2009), and a later ratification on the 15th October of the same year (Aviso n.º 18200/2009).

²⁰² These classes are delimited in the ordering plan, according to the exclusive or dominant use category in each one.

streets make up a close knitwear together with bordering parcels and plots, that are already built-up in over 50% of parcels and plots, with four or five-storey buildings; As low-density urban spaces the remaining developable urban areas, as well as the wholly or partly infrastructured urban areas.

Table 1. Classification of built-up urban areas belonging to the municipality of Ourém according to the urban network hierarchy settled in respective Municipal Master Plan

Level	Parishes	Built-up urban areas
1	Fátima	Town of Fátima, Cova da Iria, Moita Redonda, Lomba d'Égua, Aljustrel, Moimento, Casa Velha and Eira da Pedra
1	Nossa Senhora das Misericórdias/Nossa Senhora da Piedade	Town of Ourém, Ourém/Castelo, Santo Amaro, Lagoa da Carapita, Vale do Lobo, Hortas, Regato, Corredoura, Lagarinho and Penigardos
2	Alburitel	Alburitel
2	Atouguia	Atouguia, Mourã, Murtal, Outeiro do Murtal, Pinheiro do Murtal, Feteira and Fontainhas
2	Casal dos Bernardos	Casal dos Bernardos and Casal dos Moleiros
2	Caxarias/Urqueira	Caxarias, Vendas, Caxarias/Carvoeira, Pontes, Pisões, Cavadinha and Mata
2	Cercal	Cercal, Vale do Feto and Ninho de Águia
2	Espite	Espite, Cimo da Igreja, Braga, Casal Monte; Meliceira and Vale do Ugreiro
2	Formigais	Formigais, Casal da Igreja and Porto Velho
2	Freixianda	Freixianda, Abades, Várzea do Bispo, Casal do Pinheiro, Aldeia de Santa Teresa, Porto do Carro and Vale do Carro
2	Gondemaria	Gondemaria, Cidral, Fartaria, Palheiro and Cardiais
2	Matas	Matas, Achada, Casal Menino, Cubal and Barreirinhas
2	Matas	Lavradio, Vesparia and Perdigão
2	Nossa Senhora das Misericórdias	Vilar dos Prazeres
2	Nossa Senhora das Misericórdias	Melroeira and Pinhel
2	Nossa Senhora da Piedade	Vale Travesso, Casal Matos and Casal Castanheiro
2	Nossa Senhora da Piedade	Alqueidão, Cartacha, Quinta Nova and Casais da Caridade
2	Nossa Senhora da Piedade	Pinheiro, Pimenteira and Cabiçalva
2	Olival	Olival and Aldeia Nova
2	Ribeira do Fárrio	Fárrio and Reca
2	Rio de Couros	Rio de Couros
2	Rio de Couros	Sandoeira and Castelejo
2	Seiça	Seiça, Pombalinho, Outeiro, Alqueidão, Carvalho, Chão de Maçãs and Estremadouro
2	Seiça	Peras Ruivas and Pedreiras
2	Urqueira	Urqueira

3 - The remaining built-up urban areas correspond to level 3

The rules laid down in article 40th (Medium-density urban spaces in Ourém and Fátima) apply to buildings' construction and enlargement in wholly infrastructured parcels or plots in medium-density urban spaces, in the absence of Urban Development or Detail Plans.

Article 41st (Low-density and very low-density urban spaces) settles that level 2 built-up urban areas correspond to low-density urban spaces, and level 3 built-up urban areas correspond to very low-density urban spaces. However, medium-density areas may be settled through Urban Development or Detail Plans in level 2 built-up urban areas with delimited planning and management operational units (point 2. of this article).

Article 42nd (urban-use parameters for low and very low-density urban spaces) specifies the following parameters for low and very-low density spaces, respectively:

Table 2. Urban parameters for low-density spaces in the municipality of Ourém settled in respective Municipal Master Plan.

Density level	Dimension of the buildable plot (m ²)	Maximum occupation percentage or maximum implanted surface (*)	Maximum gross built index or maximum built surface (*)	Maximum waterproofing index or surface	Maximum number of floreys (**)	Maximum number of dwellings
Low	From 500 to 1200	25%	0,45	0,35	2	2
	> 1200	300 m ²	540 m ²	420 m ²	2	2

(*) Including all the built surfaces

(**) Use of attics is admitted

Table 3. Urban parameters for very low-density spaces in the municipality of Ourém settled in respective Municipal Master Plan.

Density level	Dimension of the buildable plot (m ²)	Maximum occupation percentage or maximum implanted surface (*)	Maximum gross built index or maximum built surface (*)	Maximum waterproofing index or surface	Maximum number of floreys (**)	Maximum number of dwellings
Very low	From 500 to 1500	20%	0,36	0,3	2	2
	> 1500	300 m ²	540 m ²	450 m ²	2	2

(*) Including all the built surfaces

(**) Use of attics is admitted

The urban parameters that industry-solely plots (compatible with other urban uses) must conform to are:

Table 4. Urban parameters for industry-solely spaces in the municipality of Ourém settled in respective Municipal Master Plan

Dimension of the buildable plot (m ²)	Maximum occupation percentage or maximum implanted surface (*)	Maximum gross built index or maximum built surface (*)	Maximum waterproofing index or surface	Maximum number of floreys (**)
From 500 to 2000	35%	0,4	0,45	2
> 2000	700 m ²	800 m ²	900 m ²	2

(*) Including all the built surfaces

(**) Buildings' maximum height is 7,5 m

Section II of the Municipal Master Plan of Ourém impinges on developable urban spaces. Article 43rd (Scope and main goal) features urban developable spaces as aimed at urban spreading, namely housing and respective complementary functions, and also at industrial uses compatible with other urban uses.

Point 2. of this article stresses that the conditions stated by the current regulation to urban developable spaces intend to master the urban growth and consolidate the existing urban spaces, creating urban areas provided with the required infrastructures and collective equipment, making profits on investments in built or to be built infrastructures and amenities. Urban developable spaces may result in medium-low, low or very low density spaces, according to the urban spaces they fit (delimited in the ordering plan).

Methodology to compute the abstract average gross built surface/m² in the municipality of Ourém

Within this legal and regulatory context, the methodology to compute the abstract average gross built surface/m² in the municipality of Ourém pursued the following steps: Identification of the areas encompassed by the urban perimeter of Fátima, where the Urban Development Plan of Fátima is enforced (Portaria n.º 633/95; RCM n.º 148-A/2002; Aviso n.º 2766/2009; Aviso n.º 18200/2009); Identification of the areas encompassed by the urban perimeter of Ourém (level 1 built-up areas), where the Municipal Master Plan of Ourém is enforced (RCM n.º 148-B/2002; Aviso n.º 5416/2009; Aviso n.º 18200/2009; Aviso n.º 11779/2010; DR n.º 1614/2010; Aviso n.º 7841/2011; Aviso n.º 4800/2013; Aviso n.º 4735/2013); Identification of the areas inside the urban perimeter of Fátima where the Detail Plans are enforced (Detail Plan of Avenue Papa João XXIII (Aviso n.º 15622/2009) and Detail Plan for the block formed by Francisco Marto Street, Lomba de Égua Road and Mercado Street (Portaria n.º 67/99)); Identification of the areas inside the urban perimeter of Ourém where the Detail Plans are enforced (Detail Plan of the industrial area of Casal dos Frades (Despacho n.º 195/91); Detail Plan of the Health Centre of Ourém (Portaria n.º 190/97); Detail Plan of Caridade (Portaria n.º 496/93; Declaração n.º 376/99); and Detail Plan of Quinta do Ribeirinho (RCM n.º 159/2000)); Identification of level 2 and 3 built-up urban areas in the municipality of Ourém, where the Municipal Master Plan is enforced; Application of the urban parameters correspondent to each previously identified area, in order to set up respective maximum allowed gross built surfaces, according to the applicable plans; Computation, for each area, of the concrete gross built surface/m², through the quotient between the maximum allowed gross built surface and respective territorial surface (expressed in m²/m² of land); Determination of the percentage of each of these areas in relation to the total developed and developable urban area in the municipality of Ourém; Computation of the average gross built surface/m² through the sum total extended to all considered territorial areas, of the product between respective percentage in relation to the whole studied developed and developable space, and correspondent gross built surface.

Computation of the abstract average gross built surface/m² in Fátima

The Urban Development Plan of Fátima applies to Fátima built-up urban areas and the surrounding environment - article 2nd (Territorial application scope) of the regulation of this plan (Portaria n.º 633/95).

The urban area of Fátima includes the following level 1 built-up urban areas²⁰³: Fátima; Cova da Iria; Moita Redonda; Lomba d'Égua; Aljustrel; Moimento; Casa Velha and Eira da Pedra), that amount to a total surface of 7 004 853 m². The surface of the unit of Cova da Iria (1 731 829 m²) was subtracted from that value, as it corresponds, jointly with Cova Grande, to the area where the Detail Plan of Avenida Papa João XXIII are enforced. Thus level 1 built-up urban areas where the Urban Development Plan of Fátima is enforced, amount to a total surface of 5 273 024 m².

The average maximum gross built surface/m² allowed in level 1 built-up urban areas in the urban zone of Fátima is 0,5313 m²/m² of land (Table 5).

As aforementioned, there are two Detail Plans currently enforced inside the urban area of Fátima: the Detail Plan of Avenida Papa João XXIII; and the Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado.

The regulation board of the Detail Plan of Avenida Papa João XXIII points out a gross built surface of 0,5876 m²/m² of land (Table 6).

²⁰³ These built-up urban areas correspond to planning and management operational units.

Table 5. Surfaces, allowed gross built surfaces, and average maximum gross built surface/m² inside the urban perimeter of Fátima where the Urban Development Plan is enforced

Planning Areas	Surface (m ²)	Maximum gross built surface (m ²)
Aljustrel	156.180	63.450
Fátima	1.895.800	993.860
Moita Redonda	909.780	658.500
Lomba d'Égua	521.329	357.420
Moimento	371.878	167.400
Casa Velha/Eira da Pedra	1.418.057	560.700
Total	5.273.024	2.801.330
Gross built surface/m ² (Level 1 built-up urban areas)	0,5313	

Table 6. Surfaces and gross built surfaces/m² allowed in the intervention area of the Detail Plan of Avenida Papa João XXIII.

	Housing, trade, services and tourism	Equipment facilities	Collective urban development spaces (current and anticipated)	Construction of the new church	Total
Maximum gross built surface (m ²)	374.047	63.570	137.753	33.910	609.280
Total surface of the Detail Plan (m ²)	1.036.814,0				
Gross built surface/m ² of the Detail Plan (m ²)	0,5876				

As far as the Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado is concerned, the maximum allowed gross built surface amounts to 1,2476 m²/m² of land (Table 7):

Table 7. Surfaces and gross built surfaces/m² allowed in the intervention area of the Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado

	Housing, trade and services
Maximum gross built surface (m ²)	35.558
Total surface of the Detail Plan (m ²)	28.500
Gross built surface/m ² of the Detail Plan (m ²)	1,2476

The remaining area encompassed by the Urban Development Plan of Fátima includes the following planning areas²⁰⁴: Fazarga/S. Miguel, Charneca, Tapada and Valinhos (that cover a surface of 2 665 635 m²). The maximum anticipated gross built surface/m² for these areas is 0,2627 m²/m² of land (Table 8):

When the Municipal Master Plan of Ourém was voted through (2002) (Correia et al., 2002), the urban area of Fátima amounted to 696,6 hectares, and its developable urban area to 286,4 hectares, what added up 983 hectares. In the urban area that results from the difference between these 9 830 000 m² and the surfaces of 5 273 024 m², 1 036 814 m², 28 500 m², and 2 665 635 m² (correspondent to level 1 built-up urban areas where the Urban Development Plan of Fátima,

²⁰⁴ Chapter IV (Special precepts applicable to each area) of the Urban Development Plan of Fátima, article 27º (Definition of the planning areas): UE4 – urban growth area (car parks); UC8 – north environment of Monte de Valinhos; VU1 urban park; VU2 – Valinhos (Moimento); VU3 – Fazarga; RS – urban reserve that encompasses the areas of Fazarga/S. Miguel, Charneca, Tapada and Valinhos.

the Detail Plan of Avenida Papa João XXIII, the Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado, and the remaining surface where the Urban Development Plan is enforced, respetively) are applicable the urban parameters settled by the Municipal Master Plan of Ourém.

Table 8. Surfaces and allowed gross built surfaces/m² in the remaining urban area of Fátima under the Urban Development Plan.

Planning Areas	Surface (m ²)	% of surface in relation to total surface	Land occupation index	Land use index	Gross built surface/m ²
Fazarga/S. Miguel	880.301	33,02%	0,4000	0,5000	0,2000
Charneca	443.208	16,63%	-	-	0,6586
Tapada	353.587	13,26%	0,2700	0,4500	0,1215
Valinhos	988.539	37,08%	0,3000	0,6000	0,1800
Total	2.665.635	100,00%			0,2627

This area (826 027 m²) corresponds to level 3 built-up urban areas, as settled in the Report of the Municipal Master Plan of Ourém (Correia et al., 2002). So it is subject to the urban indexes settled in article 42nd (Urban use parameters for low and very low-density urban uses). Under these circumstances the gross built surface amounts to 0,0720 m²/m² of land (Table 9):

Table 9. Surfaces and gross built surfaces/m² allowed in the remaining urban area of Fátima (level 3 built-up urban areas), under the Municipal Master Plan of Ourém.

Planning Areas	Surface (m ²)	Maximum occupation percentagem	Maximum gross built index	Gross built surface/m ²
Total	862.027	0,2000	0,3600	0,0720

After that, the average gross built surface of the urban area of Fátima is reckoned according to the following methodology (Table 10):

Computation of the percentage that each of the considered areas represent in relation to the whole developed and developable urban area of Fátima;

Multiplication of the maximum allowed gross built surface in each area by respective percentage;

The abstract average gross built surface in the urban area of Fátima corresponds to the sum of the previous values for the different considered areas, and its value amounts to 0,4262 m²/m² of land:

Table 10. Synthesis of the gross built surface/m² in the developed and developed urban areas of Fátima

	Surface (m ²)	% of surface in relation to total surface	Gross built surface/m ²
Level 1 built-up urban areas	5.237.024	53,28%	0,5313
Detail Plan of Avenida Papa João XXIII	1.036.814	10,55%	0,5876
Detail Plan for the block formed by Rua Francisco Marto, Estrada da Lomba de Égua and Rua do Mercado	28.500	0,29%	1,2476
Remaining urban area of Fátima (Urban Development Plan)	2.665.635	27,12%	0,2627
Level 3 built-up urban areas (Municipal Master Plan of Ourém)	862.027	8,77%	0,0720
Total surface of developed and developable urban areas of Fátima	9.830.000	100,00%	0,4262

Computation of the abstract average gross built surface/m² in Ourém

The urban area of Ourém includes a set of level 1 built-up urban areas that belong to the parishes of Nossa Senhora das Misericórdias and Nossa Senhora da Piedade (Ourém; Ourém/Castelo; Santo Amaro; Lagoa da Carapita; Vale do Lobo; Hortas; Regato; Corredoura; Lagarinho; and Penigardos).

As aforementioned, the following four Detail Plans are currently enforced in the urban area of Ourém: the Detail Plan of the industrial area of Casal dos Frades; the Detail Plan of the Health Centre of Ourém; the Detail Plan of Caridade; and the Detail Plan of Quinta do Ribeirinho.

The Detail Plan of the industrial area of Casal dos Frades allows a maximum gross built surface of 0,0795 m²/m² of land²⁰⁵ (Table 11):

Table 11. Surfaces and gross built surfaces/m² allowed in the intervention area of the Detail Plan of the industrial area of Casal dos Frades

	Housing, trade, services, and equipments
Maximum gross built surface (m ²)	65.000
Total surface of the Detail Plan (m ²)	817.500
Gross built surface/m ² of the Detail Plan (m ²)	0,0795

In what concerns the Detail Plan of the Health Centre of Ourém, the maximum allowed gross built surface amounts to 0,9401 m²/m² of land (Table 12).

Table 12. Surfaces and allowed gross built surfaces/m² in the intervention area of the Detail Plan of the Health Centre of Ourém

	Housing, trade and services	Equipments	Total
Maximum gross built surface (m ²)	97.097	27.000	124.097
Total surface of the Detail Plan (m ²)	132.000		
Gross built surface/m ² of the Detail Plan (m ²)	0,9401		

The Detail Plan of Caridade considers different kinds of land uses in its intervention area: ZUHM – Buildable area assigned to single-family houses; ZUHB – Buildable area assigned to blocks of flats; ZUE – Buildable area assigned to social equipment and facilities; ZI – Buildable Area assigned to industry; ZVU - Non-buildable area of urban green; ZVP – Non-buildable area of green environmental protection; ZD – Non-buildable sports area.

The maximum average gross built surface allowed by the Detail Plan – considering the maximum allowed gross built surfaces in each of its areas – amounts to 0,5710 m²/m² of land (Table 13).

In the Detail Plan of Quinta do Ribeirinho the maximum allowed gross built surface amounts to 0,5238 m²/m² of land (Table 14).

²⁰⁵ An height of 7,5 meters was admitted for industrial pavilions.

Table 13. Surfaces and allowed gross built surfaces/m² in the intervention area of the Detail Plan of Caridade

	ZUHM	ZUHB	ZI	ZUE	Remaining	Total
	Housing	Housing	Workshops	Equipment		
Maximum gross built surface (m ²)	4.200	39.520	3.600	6.200	6.440	59.960
Total surface of the Detail Plan (m ²)	9.600	32.500	11.000	20.900	31.000	105.000
Gross built surface/m ² of the Detail Plan (m ²)	0,4375	1,2160	0,3273	0,2967	0,2077	0,5710

Table 14. Surfaces and gross built surfaces/m² allowed in the intervention area of the Detail Plan of Quinta do Ribeirinho

	Housing, trade, services, and equipments
Maximum gross built surface (m ²)	9.330
Total surface of the Detail Plan (m ²)	17.813
Gross built surface/m ² of the Detail Plan (m ²)	0,5238

When the Municipal Master Plan of Ourém was approved (2002), the urban area of Ourém amounted to 287,3 hectares, and its developable urban area amounted to 107,9 hectares, what adds up to 395,2 hectares (that supposedly represent the current situation) (Correia et al., 2002).

Thus, the remaining area of level 1 built-up urban areas of Ourém has a surface of 2 879 687 m², that results from the subtraction from its developed and developed urban area (3 952 000 m²) of 817 500 m², 132 000 m², 105 000 m², and 17 813 m² (correspondent to the intervention areas of the Detail Plan of the industrial area of Casal dos Frades; the Detail Plan of the Health Centre of Ourém; the Detail Plan of Caridade; and the Detail Plan of Quinta do Ribeirinho, respectively).

The urban parameters settled in article 40th (Medium-density spaces in Ourém and Fátima) of the regulation of the Municipal Master Plan of Ourém are enforced in this area (where the maximum net land use index is 0,75, that is to say, the maximum allowed gross built surface amounts to 0,75 m²/m² of land) - considering the characteristics defined in article 39th, 2.a) concerning the urban areas inside the urban perimeters of Ourém and Fátima.

The average gross built surface/m² comes up, finally, as 0,6119 m²/m² of land, adding up the gross built surfaces of the different considered areas, weighed by the correspondent percentages in relation to the total surface of the urban area of Ourém (Table 15).

Table 15. Synthesis of the gross built surface/m² in the urban area of Ourém

	Surface (m ²)	% of surface in relation to total surface	Gross built surface/m ²
Detail Plan of the industrial area of Casal dos Frades	817.500	20,69%	0,0795
Detail Plan of the Health Centre of Ourém	132.000	3,34%	0,9401
Detail Plan of Caridade	105.000	2,66%	0,5710
Detail Plan of Quinta do Ribeirinho	17.813	0,45%	0,5238
Remaining urban area of Ourém	2.879.687	72,87%	0,7500
Total surface of the urban area of Ourém	3.952.000	100,00%	0,6119

Computation of the abstract average gross built surface/m² in level 1 and 2 built-up urban areas in the municipality of Ourém (excluding Fátima's).

In low-density (level 2) and very low-density (level 3) built-up urban areas are enforced the urban parameters settled in article 42nd (Urban-use parameters for low and very low-density urban spaces) of the regulation of the Municipal Master Plan of Ourém.

As far as level 2 built-up urban areas are concerned, the whole developed urban area amounts to 1 507,5 hectares and the developable urban area amounts to 736,9 hectares, what adds up to 2 244,4 hectares (Correia et al., 2002). According to article 44th (Edification in urban developable spaces), point 2. of the regulation of the Municipal Master Plan of Ourém (RCM n° 148-A/2002), the precepts settled in articles 38th, 39th, 40th, 41st and 42nd are applicable to urban developable areas. So, in these level 2 developed and developable urban areas are enforced the urban parameters settled in articles 41st and 42nd.

Thus the allowed gross built area amounts to 0,1125 m²/m² of land (Table 16).

Table 16. Surfaces and gross built surfaces/m² allowed in level 2 built-up urban areas under the Municipal Master Plan of Ourém.

	Housing, trade, services, equipments, and industry
Maximum percentage of land occupation	0,25
Maximum gross built index (m ² of gross built surface/m ² of land)	0,45
Developed and developable urban area of level 2 built-up urban areas (m ²)	22.444.000
Maximum gross built surface (m ²)	2.524.950
Gross built surface/m ² of level 2 built-up urban areas	0,1125

The total surface of level 3 developed built-up urban areas amounts to 2 310,3 hectares, and of developable urban areas amounts to 620,4 hectares, what adds up to 2 930,7 hectares.

The application of the urban parameters correspondent to very low-density areas (article 42nd) leads to an average allowed gross built surface of 0,0720 m²/m² (Table 17):

Table 17. Surfaces and gross built surfaces/m² allowed in level 3 built-up urban areas under the Municipal Master Plan of Ourém.

	Housing, trade, services, equipments, and industry
Maximum percentage of land occupation	0,2
Maximum gross built index (m ² of gross built surface/m ² of land)	0,36
Developed and developable urban area of level 3 built-up urban areas (m ²)	29.307.000
Maximum gross built surface (m ²)	2.110.104
Gross built surface/m ² of level 3 built-up urban areas	0,0720

Computation of the abstract average gross built surface/m² in the municipality of Ourém

The abstract average gross built surface/m² in developed and developable urban areas in the municipality of Ourém amounts, therefore, to 0,1716 m²/m² of land, according to gross built surfaces, weighting the different studied areas by respective percentages in relation to the total developed and developable municipal urban area (Table 18).

Table 18. Synthesis of the surfaces and gross built surfaces/m² of the different delimited areas in the municipality of Ourém, and abstract average gross built surface/m² in the whole municipality.

	Surface (m ²)	% of surface in relation to total surface	Gross built surface/m ²
Total surface of the urban area of Fátima	9.830.000	15,00%	0,4262
Total surface of the urban area of Ourém	3.952.000	6,03%	0,6119
Developed and developable urban area of level 2 built-up urban areas (m ²)	22.444.000	34,25%	0,1125
Developed and developable urban area of level 3 built-up urban areas (m ²)	29.307.000	44,72%	0,0720
Total developed and developable urban area of the municipality of Ourém	65.533.000	100,00%	0,1716

Conclusions

Within the scope of the revision of the whole legislation concerning land, territorial planning and urban development – currently underway in Portugal – this article tried to show how (current and/or anticipated) urban morphologies support the development of territorial management tools able to ensure the economic and financial sustainability of urban developments, as well as the sustainability of the municipalities they belong to.

The computation of the municipal abstract average gross built surface/m² further supports reaching other goals that underlie the new land planning and management, territorial ordering and urban development paradigm. In fact, it stands as a benchmark for assessing current and new territorial management tools, in order to ensure higher equity and a fair redistribution of costs and benefits that arise from urban developments among all the inhabitants within a certain municipality.

Indeed, the municipal abstract gross built surface/m² proposed in the current article can be further integrated as a parameter or indicator in different land policies, especially the fiscal-oriented ones that allow, namely, to: Assess, in a clear and objective way, the allowed average gross built surface/m² of specific urban developments, in comparison with the municipal average gross built surface/m²; Contribute to a more accurate definition of municipal development charges intended to fund infrastructures execution, maintenance, and reinforcement provided by the municipality (Almeida et al., 2013; Leitão, 2011; Rebelo, 2013a; Silva, Deus and Tenedório, 2012); Develop new territorial planning and management tools aimed at capturing the surplus-values that arise from planning decisions or public investments, so that municipalities can reassign them to social purposes (Rebelo, 2013b); Clarify the origins of funds, and accurately quantify the contribution of the (current or proposed) territorial management tools to the strengthening of municipal finance, thus ensuring municipal economic and financial sustainability; Assure a better intra-municipal equity in the distribution of benefits and charges that accrue from urban development processes.

The morphological sense of commerce – theoretical review and lessons learned in four Portuguese medium sized cities

Miguel Saraiva, Paulo Pinho

CITTA - Research Centre for Territory, Transports and Environment, Faculty of Engineering, University of Porto, Portugal. E-mail: dec08020@fe.up.pt, pcpinho@fe.up.pt.

Abstract. *Shopping has been considered the principal wealth-generator of post-modern societies. Yet, two elements continually elude current theories and practices about the role of commerce on a wider perspective. Rarely is it considered an active agent in the structuring of the city and, furthermore, most studies have solely focused on the geographical, economic and social dimensions of shopping, neglecting its morphological dimension. Only in the last 10 years have authors addressed this perspective, although sporadically and presenting focused views, resulting in a lack of knowledge and, ultimately, in the lack of proper public policies. This paper aims to address the structuring nature of commerce and the influence of its morphological component. For that it combines knowledge from various fields of research and a large array of morphological variables at various resolution levels. Using as test-beds four Portuguese medium-sized cities, GIS-models containing commercial, morphological, structural and temporal variables were produced, explored and compared. Findings include i) the definition of commercial / morphological indicators, that can constitute values of reference or comparison for commercial policies and other planning studies; ii) the evidence that morphological, rather than statistical similarities generate, on the micro-scale, more commercial similarities; and iii) the main bridging aspects between commercial activity and the form and structure of cities.*

Key Words: commerce; medium-sized cities; urban morphology; Space Syntax; urban planning

Introduction – From geography and economy to morphology

Ever since the Industrial Revolution, when the ‘shop’ gained a permanent physical location within the city and became ‘aware of itself’ (Pessoa, 1926), the act of shopping has become an integral part of city-living. If cities have evolved from ‘artifacts’ (Karaman, 2001) to ‘organisms’ (Moudon, 1997), commerce has evolved from being considered just an ‘economic activity’ to an ‘experience’ (Pine, Gilmore, 1999), as the paradigms of both commerce and consumption change (Cachinho, 1994). Indeed, there is a growing interest in the proven capacity commerce has of driving urbanization processes, and of promoting and developing successful urban spaces, boosting their economic and social value (Whysall, 1995; OdC, 2000a; Evers, 2001; Lowe, 2004, 2005; Emery, 2006; Fernandes, 1994; Balsas, 2000, 2001; Moreira et al, 2006).

Yet this understanding of commerce as a structuring element of the ‘organic’ city has never been given enough importance, nor in the literature nor in policy-making (Balsas, 2001; Musso, 2010; Grant and Perrott, 2011). Commerce has mostly been considered a consequence of markets and urban and social behaviours (Borchert, 1998), i.e. commerce was deemed to seek the best locations after-the-fact, and furthermore no-one assumed that the presence of retail spaces could be, in itself, a cause for the shifts in value of given locations.

In this framework, various fields of research have studied commerce. Historians and geographers have weaved the evolution of commercial patterns and hierarchies over time (Kwan-Yiu, Kong-Sut, 1971; Guy, 1976; Lee, McCracken, 1982; Axenov et al, 1997; Borchert, 1998; Wang and Jones, 2002; Fernandes, 2003; Fernandes and Martins, 2003; Shan, 2004,

Cachinho, 2002, cit in GECIC, 2005), based on hierarchical organizational theories such as the Central Place Theory, the Spatial Interaction Theory, the bid-rent theory or the principle of minimum differentiation (for a review see Clarkson et al, 1996; Saraiva, 2013). Sociologists have tried to understand the behaviour of the shopper (Gregson et al, 2002; Sinha, 2003; Sinha and Unyal, 2005; Sarma, 2007) and of those who sell (Varanda, 2004). And economists have dwelt on the values of location, in terms of market-shares (the retail location theory – RLT), using various mathematical models (reviews in Yrigoyen and Otero, 1998; Hernandez et al, 1998, Mendes and Themido, 2004, Reynolds, 2005, Saraiva, 2013). In this case the relationships with the external environment, with the location mix and with the consumer, are only briefly considered as catalysts for the optimization of sales.

These studies perform, all things considered, ‘simple’ geographical pattern comparisons, between the location (or future location) of the store with the value (economic, social or statistical) that location generates. The site may ‘make the shop’ (Alexander et al, 1999), but the notion of location entails much more than a set of coordinates or statistics, the economic capacity of the customers in the catchment area, or the market competition. Location is accessibility. Location is built landscape. Location is layout and design. In other words, location is also morphology.

The morphological sense of commerce

In 1958 Nelson wrote: ‘the emotional aspects of a location can be important to the success of a store or a shopping centre as the more obvious characteristics of convenience and access’. But his prophetic afterthought remained unanswered for decades: ‘But can stores or shopping centres be as important to the emotional aspects of location?’ Only in the past decade, authors have been calling attention to the lack of an urban morphology dimension in the commercial literature (Van Nes, 2005; Sarma, 2006) and to the lack of knowledge on how urban form affects the spatial distribution of retail activities (Villain, 2011). Urban environment conditions have turned, according to Axenov et al (1997), into the major group of factors that shape the commercial spaces’ market.

Yet most morphological studies still present a narrow view, are context-specific, and lack an interdisciplinary approach. Initial studies followed, more than they actually assumed, previous geographical / economic research, overlapping commercial distribution maps with those of socio-economic densities (Barke, 1998; Joosten and van Nes, 2005; Kompil and Çelick, 2006; Smith, 2006) or of land-use and transport networks at city level (Joosten and van Nes, 2005; Jingman, 2009; Villain, 2011), or even at regional or national level (Marques, 2003). Joosten and van Nes (2005) noted that most literature focused on the macro-scale, and had not yet zoomed into the micro-scale (street, building).

And when it does have, there is also a distinction, seldom overcome, between the study of the store itself and the study of the urban environment the store is part of. The first has mostly been non-morphological, interpreting type of activity, sales data or employee information. There are nonetheless some exceptions. Barke (1998) analysed window size, building type and occupation, and the existence of storage facilities, noting distinct morphological characteristics, highly inter-correlated, in buildings with only commercial use. These were also more correlated with the catchment area population than that of the local area. Allegri (2010) analysed the evolution of the physical layout of shopping centres and arcades in the city of Lisbon, whilst crime researchers have also analysed store layout (Saraiva, 2008, 2011) or product design (Lester, 2001), albeit with different purposes. The second, the analysis of the surrounding store environment, has read as yet another time-line of context, unrelated to the intrinsic characteristics of both space and commerce. The works of Fernandes (1993) or Tokatli and Boyaci (1999) display demographic, urban and political changes on one side, and commercial dispersion changes on the other, not linking them. Tokatli and Boyaci (1999) go as far as to mention the ‘changing morphology of commercial activity’ yet, in truth, only occasionally are

references made to streets, floors and building types. The inverse happens in many commercial urbanism projects, and in marketing and place-attraction studies (Teller et al, 2010), which discuss physical improvements to exterior elements such as streets, parking spaces, shop windows, or urban furniture, aiming to produce attractive environments able to induce shopping. Yet, in all, there fails to be a direct connection between particular stores and their surrounding morphological context.

This connection has nonetheless started to steadily emerge in the literature. Yoshida and Omae (2003) and Jostens and van Nes (2005) have compared store dispersal with the properties of blocks and buildings. For the first authors commercial blocks are distinctly associated to larger areas, volumes and building-to-land ratios. For the second, stores tend to full block typologies, characterized by high floor space index and build up street sides, preferably of smaller size and in medium-density zones, usually near main junctions or along the main streets. Only chain-stores and shopping centres tend to occupy non-block typologies.

The relationship of the store location with the accessibility of the network has also been the object of Space Syntax literature, or analogue models. According to Hillier and Iida (2005), activities that depend on movement will follow the grid's logic, and there will be a gradation according to the necessities of each particular activity. Morphology is here characterized through concepts of connectivity, either distance to closest intersections (Villain, 2011), or the weight of the store's street segment in the network, according to the so-called 'integration' or the 'betweenness' of the grid. Jingman (2009), using segment analysis in Chinese cities, concluded that city's commercial centres exactly correspond to city's syntax centres, both at a local and a global scale, and that almost all large-scale stores are directly located within sub-local syntax centres, in places connected to major thoroughfares and bus routes. Likewise, for van Nes (2001, 2005) shopping areas are only successful if they are among the highest integrated streets and the higher the density of streets in the vicinity, the more intense is the shopping street in terms of number, size and variety of shops. Yet the same author, in Berlin, found a weak co-occurrence between integration and the presence of shops (Joosten and van Nes, 2005) and Porta et al (2007) were keener to defend that the strongest correlation occurs with global 'betweenness' rather than with 'integration'. Furthermore some authors believe that this is not entirely true for all cities and all types of activity – the 'gradation' Hillier had already hinted to.

Sarma (2006), Hossain (1999, cit in Sarma, 2006) and Villain (2011) agree that commercial spaces whose sales (movement) are generated by their own attracting potentialities (anchor or specialized stores) have the tendency to be clustered together in central locations, although surviving in isolation. On the other hand, functions whose movement is just attracted coincidentally, like convenience and multi-purpose shopping, because they are more affected by competition and movement, are more dispersed, although in spatially strategic locations with high through-movement potential and serving local catchment areas. Only first necessity and some convenience stores appear to be a global phenomenon in the market, correlating both globally and locally with through-movement. This leads Sarma (2006) to conclude that distance is directly proportionate to social and economic class in terms of movement and in terms of shops. Teklenburg et al (1994) also stress that in suburbia, although the busiest shopping street is in one of the most integrated lines of the axial map, other commercial streets or department store locations are not. They established that in most cases where the most integrated lines for pedestrians did not coincide with the major store locations there was a co-occurrence of pedestrian and intense vehicular traffic.

Methodology

Although the studies that have tried to establish a connection between urban morphology and commercial activity are becoming more frequent, they seem to suffer from an exaggerated spatial and theoretical focus. Commercial, economic and geographical studies seldom look at

the micro-scale morphological element, syntactic approaches do not regard any morphological characteristic other than the location in the grid, and morphological studies do exactly the opposite, associating the measure of form and structure with the mapping of evolutionary geographical patterns, something which led Conzen (1980) to state that these studies were ‘amorphological’, and Whitehand (2007) that a ‘typological’ component, i.e. land and building use, and an interdisciplinary integration was missing. Each study usually uses only one method for variable comparisons, does not usually divide stores by activity or type, and dwells exclusively on one city or urban area. Joosten and Van Ness’s (2005) conclusion that stores are located preferably in full-block typologies may hold for Berlin, but it is easy to question its validity elsewhere.

In this context, this article wishes to synthesize the first findings of the research performed by Saraiva (2013), whose main goal was to establish to what extent the morphological environment is connected to the location, characterization and performance of commercial spaces. A multiple case-study approach and a multidisciplinary variable-analysis approach, were carried out. Four Portuguese medium-sized cities: Vila Real, Aveiro, Leiria and Évora, were selected, in order to get a diversified sample, according to their geographical location, their number of inhabitants (20-60 thousand), their structural importance in the urban network and their permeability to new commercial formats and commercial-urbanism programmes. The study area was made coincident with the so-called urban perimeter as defined in the respective municipal master plan. Within this perimeter, commercial and morphological variables were collected, street by street, building by building and store by store. The cities were later divided into two areas: the ‘city center’, and the ‘periphery’, which was also, in turn, divided into homogeneous areas (e.g. ‘residential areas’, ‘industrial/commercial areas’), and the analyses were conducted at these different resolutions.

According to recent Urban Morphology literature, the ‘morphological sense’ could no longer be described as just the study of form, but of form and function over time, in a given context, i.e. form and structure, that is characterized as having morphological, but also topological and typological components, analysed according to three resolution-levels: street, neighbourhood and territory (Conzen, 1960; Lamas, 1989; Cannigia and Maffei, 1993; Moudon 1997; Karaman, 2001; Whitehand, 2001, 2007, Saraiva, 2013). Figure 1 portrays the general research framework in which these notions are present.

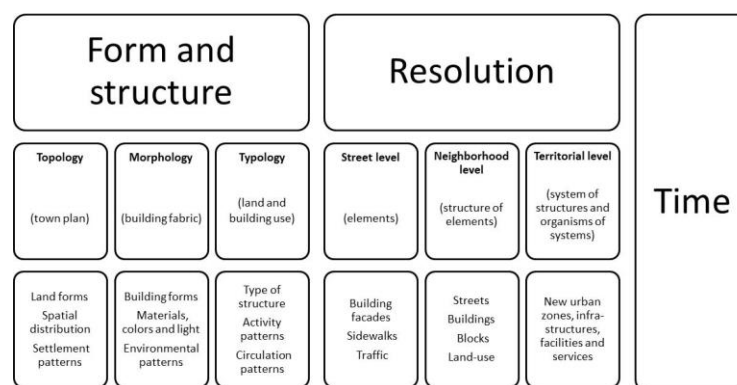

Figure 1. Components of the form and structure of a city, according to urban morphology literature (source: Saraiva, 2013).

Figure 2 lists the morphological variables considered in the research. Streets were characterized according to their type (exclusively pedestrian or not), width, quality and the size of sidewalks, building characteristics, an accessibility measure and the amount of movement. These last two were measured through Space Syntax. According to Hillier and Vaughan (2007),

60 to 80% of movement flows can be accounted by the configuration of the grid. Sixteen different radii (in meters) were considered, and the results were divided into six quantiles, ranging from the most central (first) to the most segregated (sixth). Blocks were characterized according to their typology (full, hollow), land-use mix, statistical information concerning families and dwellings, and a set of distances (between built elements, stores and store types). Buildings were characterized according to their type and amount of occupation, their height, area and volume, and their age (before and after 1975), style and preservation. A wider contextualization based on planning, historical and geographical backgrounds, expressed the ‘territorial level’ resolution.

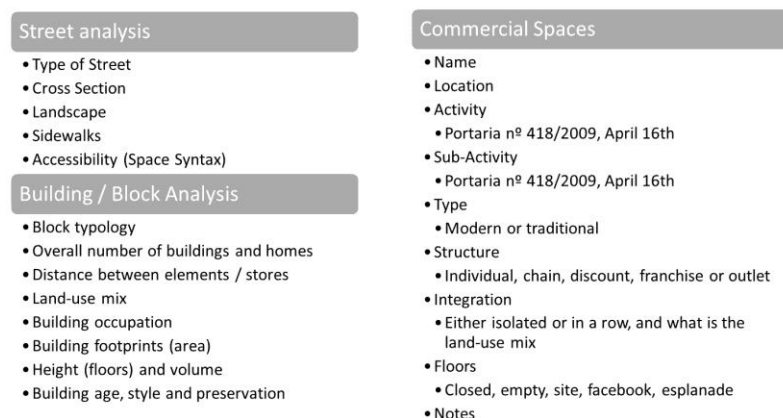

Figure 2. Morphological and commercial data collected in the research.

The collected commercial variables can also be seen in Figure 2, and are intended to answer more specifically to the ‘typology’ component. These have not changed significantly since earlier works on hierarchical retail geography and location modelling (Kwan-yiu and Kong-Sut, 1971; Guy, 1976; Lee and McCracken, 1982). The classification by activities and sub-activities (e.g. ‘Food & Beverages’ and ‘Butcher’, respectively) was based on the Portuguese legislation (Portaria nº 418/2009 of April the 16th), even though a more expedite ‘retail categories’ division, based on necessity, presented by Sarma (2006), was also used²⁰⁶. Stores were also categorized by their type (modern or traditional – Fernandes et al, 2000), their business model (individual or family-owned, chain, franchise), their integration in the building (building type and occupation, and how much space they occupy) their integration in the street (relation to other stores), their web-connection and their status (open, closed or empty).

During 2011 (the year of the most recent population Census) a total of 7.898 individual stores in the four cities were catalogued, and the information was uploaded into a GIS platform. Following Saraiva (2013), research was carried out in five main stages: an overall geographical, organic and statistical definition of the four cities; the assessment of the physical distribution of commerce; an extensive commercial characterization; the characterization of blocks and buildings containing commerce; and the characterization of streets containing commerce. This paper focuses on the last two stages, although the analysis is transversal and closely related to the other three stages as well.

²⁰⁶ Sarma (2006), inspired in Eaton and Lipsey (1982), divides commercial spaces in six categories: M1 (Multipurpose 1 – related to first necessity goods of local accessibility), M2 (Multipurpose 2 – rely on a larger customer base, such as banks or bookstores), MC (Multipurpose-Comparison – like fashion, telecommunication or sporting goods), C (Comparison – such as home or car related products) and S (Single Isolated Purchase).

Results and discussion

One of the most striking findings was the great commercial similarities between the case studies when the differences in study area and number of inhabitants were taken into account. The four cities have, approximately, the same number of inhabitants per store, stores per urban area and per street length, similar hierarchical commercial structures and location patterns, and similar percentages and distributions of store type, structure and status (Saraiva, 2013). When morphological variables are placed over these distributions, the similarities are maintained which can only mean that the distribution of stores is not random, depends on form and structure, and can be quantified. Accordingly, commercial spaces are usually in buildings with similar average heights (3-4 floors), with similar areas²⁰⁷ and volumes per store, and the same overall number of stores per block (6) – see Table 1. There are also similar hierarchical commercial street networks in all cities (from the central pedestrian street to the suburban thoroughfare), and there are even similarities in the distribution of stores that are in buildings constructed after 1975. Their percentage is approximately the same in all peripheries (around 70%), and so is, in all four cities, and for $r = n$, the percentage of these in the segments of the second and third quantiles of integration and choice (respectively 60% and 40% of buildings – Figure 3).

Obviously, there are exceptions, most of which are a consequence of particularities different cities present. For example, Évora never has similar indicators whenever building height or age is a variable, because the city centre is a world heritage site. The rural nature of Vila Real's periphery also leads to fewer stores, which reduces some indicators. Nevertheless, these exceptions usually occur in only one city. Furthermore, most of the indicators that are not in the same order of magnitude in all or in three of the case studies, are similar in pairs. And these pairings seem to be much less dependent on economic and even commercial variables (such as purchasing power, degree of local economic development and overall number of stores), and more on the morphological ones.

Table 1. Commercial building and block data, by cities, by city centres and by peripheries.

Cities	Vila Real	Aveiro	Leiria	Évora
City	183	258	244	204
City center	140	147	144	101
Periphery	292	403	376	300
City	3,71	3,76	3,77	2,23
City center	4,1	3,97	4,26	2,45
Periphery	2,82	3,49	3,14	2,03
City	233	358	442	441
City center	99	154	173	172
Periphery	134	204	269	269
City	6	6	6	4
City center	10	8	8	5
Periphery	3	5	4	3

Leiria and Aveiro are larger, more developed cities with more stores, commercial area and diversified store types, something which appears to corroborate Barke's (1998) proposal that commercial development is dependent on the regional number of inhabitants. Yet, when comparing store data with network and building properties this does not ring true. The similarities are clearer between Leiria and Vila Real, and between Aveiro and Évora (as it is seen in Figure 3 for local radii), simply because, in each pair, the cities have much more in

²⁰⁷ The store was deemed to occupy the whole implementation area of the building.

common in terms of form and structure. Exploring this idea, several considerations can be made.

Figure 3. Percentage of the total number of stores located in post 1975 buildings that are in the second and third quantiles of integration and choice, for all considered radii.

The first, which is often neglected in commercial studies, is that it is virtually impossible to dissociate the ‘store’ from the building it is in. Only one in five stores (and one in ten in Aveiro) is in a purposely-built structure for accommodating exclusively commercial-use. It is then safe to assume that in most cases these buildings were erected bearing in mind the specificities of the existing other uses in upper floors (mostly residential), and not those of commercial spaces. The morphological variables associated to the store are therefore not their own, but are related to the building they occupy, and to the street and the block in which that building is located. If this establishes the building as the most important morphological element that influences commerce it also gives strength to the hypothesis that commerce is a mere consequence of land development.

But this constitutes a half-truth. This research found that residential neighbourhoods without stores are not crossed by main streets, are usually in segregated areas of the network, have closed and small street and block structures, and only seem to influence the structure of the public transport network, as they attract transit stops. Residential buildings with stores, however, assume an entirely new significance. In the city centres major traditional ground-floor commercial streets have been maintained, despite the proliferation of commerce in new centres and in main residential localities. The weight in these locations of activities such as MC, M1 and M2 (see footnote 2) has actually been crucial in the conservation of their liveability but this is not the only reason (all cities have, for example, 80-90% of all their fashion stores in just the main central streets). Structurally these corridors constitute the most central or travel-through locations in the city centres, so it can be said that commercial construction has influenced centrality instead of being a consequence of it. Vila Real’s secular and central pedestrian street is still one of the most integrated segments of the entire city-network. But, at the same time, this position of centrality may also explain why stores have established there and why they have a continuous success, which can mean that Nelson’s two questions may have exactly the same answer as ‘who came first, the chicken or the egg?’

This duality is maintained when recent construction containing commercial spaces is analysed. On one hand, these new buildings are generally located in the most central lines possible (‘integration’), but also in the lines with the greatest travel-through potential (‘choice’) when in peripheries, which seems to suggest that their location is to some extent dependent on the pre-existing network structure. But, on the other hand, the appearance of these new buildings, especially in the urban peripheries, has been simultaneous to the opening of new axis (the plot by plot development formed the street), so they have influenced, in their own right, the properties of the network, particularly at the local level, where only 20% of stores in post-1975 buildings are in segments of the last three quantiles (Figure 4). Consequently, new streets with

commerce have generated larger local centralities influence radius by establishing a connection to, or becoming, the main peripheral axis. This not only grants greater access of surrounding areas to the local commercial poles but also permits a greater connection to the thoroughfares leading to the city centre, maximizing their feeding capacity.

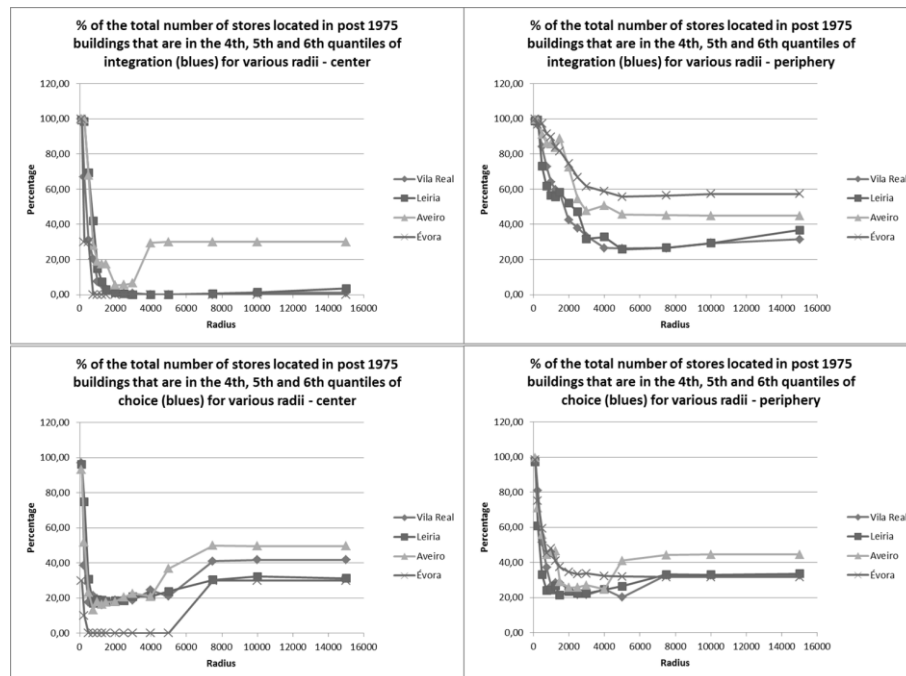

Figure 4. Percentage of the total number of stores in the centers and in peripheries, located in post 1975 buildings that are in the last three quantiles of integration and choice.

These new buildings are associated to specific morphological characteristics, which however seem to depend more on the location inside the urban perimeter than actually on the type of commerce they contain. The number of commercial poles of recent formation, as well as building heights, road-size and road complementarity decreases and block area increases with the distance from the centre. This contradicts the works of Yoshida and Omae (2003) or Joosten and van Nes (2005) that allocate specific, non-changeable, morphological features to commercial spaces. With the exception of particular store types which tend towards specific locations (like commercial services generally seeking buildings with other services), most commercial variables, particularly in the centres, have even distributions between the various types of buildings and blocks, with the only particularity that they constantly tend towards the larger side of blocks. At the same time, modern stores are very rarely in buildings and neighbourhoods constructed before 1975, which may mean new stores need new buildings. Stores in these buildings are in greater number, closer together ('door to door') and more spatially organized, which increases the chances of success as commerce performs better in proximity. 'New' buildings are usually located in larger blocks (a prevailing tendency for commercial spaces), the stores therein have more esplanades comparatively – use more public space – and as they usually are farther away from the street they also condition size and type of the sidewalks. This means that commercial buildings condition blocks, sidewalks and streets.

In any case, exclusively commercial buildings also impact on the landscape. Commercial arcades, shopping centres and warehouses obviously possess the greatest areas and volumes. They can also be extremely beneficial to revitalize main street shopping, as the literature suggests, but in these case studies they are only successful if they are close to pre-existing main shopping axes, regardless of overall accessibility, and if they have a limited number of store spaces. On the contrary, in the peripheries, large shopping centres appear and survive in isolated

areas, but they quickly stimulate commercial and residential development close-by. Actually, they seem to appear more frequently in peripheries without clearly defined centralities. Considering the example of Aveiro, a city with various shopping centres in the periphery and that, over the years, has linearly expanded through edge-roads, it could be speculated whether the lack of well defined commercial and urban centres cannot influence the appearance of these spaces.

Other than the type, age and nature of 'buildings', commercial variables seem to be more affected by the form and organization of the city. This structure obviously conditions the characteristics of the segments that form the network, of which store types seem to depend. Actually, they are more affected by this positioning (centrality, through-movement, closeness to an element) than by any other morphological characteristic of that position. But, at the same time, this position also conditions the morphological characteristics of the elements, because these are likely to change from the centre to the periphery, and from the main local road to segregated neighborhoods, and it also conditions how localities are connected between themselves and how hierarchies are built, something which, again, affects commerce.

For one, 'streets' are the second greatest morphological element, especially in the periphery where most commercial clusters favour through-movement (70% of stores are in high quantiles of choice, against around 40% in high integration quantiles), and where urbanized ring roads, expansion thoroughfares, and local or regional roads passing through the centre of localities are the distributors of development, as most localities tend to develop around or facing them. Greatest connections mean more commercial strength, not only of the ribbons per se, but also of the poles these ribbons connect. Connection means continuity, and in these concentrations the number of stores reachable is proportional to the distance travelled. When continuity is broken, the development and type of the commercial poles in the extremities change. In Vila Real's centre, for example, there are no commercial ribbons connecting the older and newer commercial centres. This may be one of the reasons why the second ones have still not been able to surpass the first. A link is a natural element for change, rather than a complete and abrupt shift in position. Other non-urbanized and non-commercial connecting axes can also be prejudicial for development. Ring roads in Aveiro and Leiria, for example, decrease the accessibility of the main streets and consequently of the main commercial areas. In Vila Real and Aveiro the lack of connection points between the centre and the periphery also segregates several commercial poles inside residential neighbourhoods, and makes it more difficult to access the centre. This causes the creation of competing stronger poles outside the city centre, obviously changing the morphological landscapes and development capacity of these areas. On the other hand, in Vila Real and Leiria the thoroughfares that unite different localities become, at the extremities, main local streets. Because the axis is the same, this considerably improves both the through-movement potential and the centrality of these localities, which helps to maintain their commercial structures, at the same time as it stimulates continuous development. The same does not happen in Aveiro and Évora, where the connections between main local roads of different localities, and between these and the centre, are not direct, despite the existence of very high through-movement axis, as is depicted in Figure 5 concerning Évora. This hinders the creation of centralities, and allows for older traditional axes to be substituted by stronger commercial poles in multi-family buildings located in or around the main through-movement axes. This peripheral store necessity (to be near 'choice' axes) clearly influences the location of the building and, consequently, it influences the location of all uses in the building.

Therefore, the form of the city can also influence commercial behaviour. Leiria and Évora have shopping centres inside the urban perimeter, and central traditional commercial areas inside the centre, unlike Aveiro and Vila Real, so, naturally, they have a clearer hierarchical and commercial structure from the core to the periphery, which increases the centrality range and the local 'choice', attracting specific activities accordingly. As a result, the closest peripheral localities are more connected to the centre, which should explain why these two cities have more developed communities, overall, in the periphery. In the peripheries of Aveiro and Évora, the expansion in edge-axes (as is clearly seen in Figure 5) and the lack of closed hierarchical

communities is negative, in a sense that it produces weaker commercial centralities, but positive, in a sense that zones gain multiple hierarchical purposes, something which can influence variables like 'building height' and 'pedestrian accessibility'. Despite the similarity in the overall physical location patterns of stores in the same hierarchical zones of different cities, the morphological composition of these zones may be different due to these nuances, which are caused by residential areas, commercial buildings and accessibility. These are then three crucial elements affecting the 'emotional aspects of location'. On the other hand, symmetry, like the one found in Évora, also contributes to the creation of similar 'integration' and 'choice' patterns, i.e. stronger axes that are attractive to stores. This, in turn, influences the 'emotional aspects of stores/buildings with stores', so it is rather difficult to ascertain where the cycle begins and ends. Other physical constraints have also been proved to affect morphological characteristics of commercial blocks. Slope, for example, can affect geometry and hinder urban and commercial expansion.

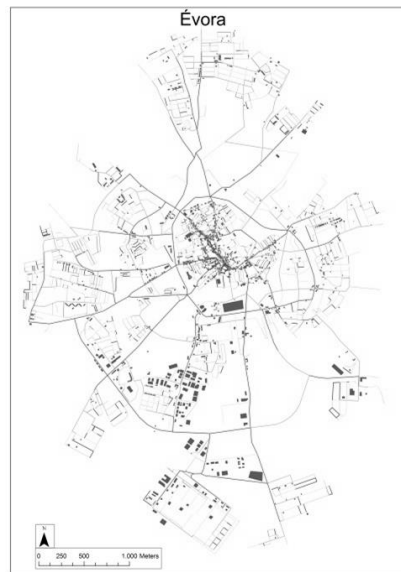

Figure 5. Évora choice map for $r=n$. Buildings are not represented, but stores are signalled with a green colour.

Consequently, these physical variables and the historical expansion of the city commercial landscape seem associated to the appearance of 'closed' and 'empty' stores. The first are generally in older areas, which have lost their vitality and, comparatively, their spatial attraction (due to changes in the network), whilst the second are usually in new neighbourhoods. The number of these is sometimes so excessive in new commercial poles in residential areas that it has to necessarily mean that these stores lack of success is not a consequence of location or competition, but simply of a lack of market need for more store space. As the centres are the greatest commercial destinations, stores therein are hardly in segregated segments, so conclusions are hard to draw. In the peripheries, however, we can see that, although stores are generally not on global centralities, if they are not even in local centralities / destinations then their chances for success are much reduced. Even so, local centrality may not necessarily be a guarantee of success, because what stores need in the periphery is to be in axes of high 'choice' potential or, at least, at the distance where they can be reached easily. For 'integration', and for $r < 2000$, more than 70% of closed and empty stores in the peripheries are in segregated segments. Furthermore, over 80% of these non-open stores are in buildings constructed after 1975, which helps to understand why older axes still withhold and why the construction of buildings containing commercial spaces cannot occur in any given location inside the urban perimeter (Figure 6). The drop to zero in Vila Real is explained by the rural nature of its

periphery, as stated before. Stores not on the ground floors are also comprehensibly unpopular and perform worse.

These findings can definitely dispute the hypothesis presented by most Space Syntax researchers that stores are preferably located in first quantile segments, and also Jingman's (2009) findings that a city's various centres correspond to various syntax centres. Indeed, these types of research are generally conducted in the centres of large cities. As Teklenburg et al (1994) had already suggested some twenty years ago, the commercial landscape in smaller cities has a different behaviour, especially outside their centres. If in the centres stores seek mid-range centrality, in the peripheries they seek through-movement, benefiting much more from global than from local 'choice'. Stores do not want (for market reasons), cannot (for financial reasons) or are unable (for structural reasons) to be in the first quantile segments, which are often longer connecting roads or service areas. Because they seek movement rich locations, but also areas closer to a larger clientele (i.e. residential areas) and corners, they stand most favourably on perpendicular roads to the main streets and on intermediate axes of the network. For radii over $r = 3.000$, over half of the stores are in the second and third quantile 'integration' lines and between 40%-50% of the stores are in the second and third quantile 'choice' lines.

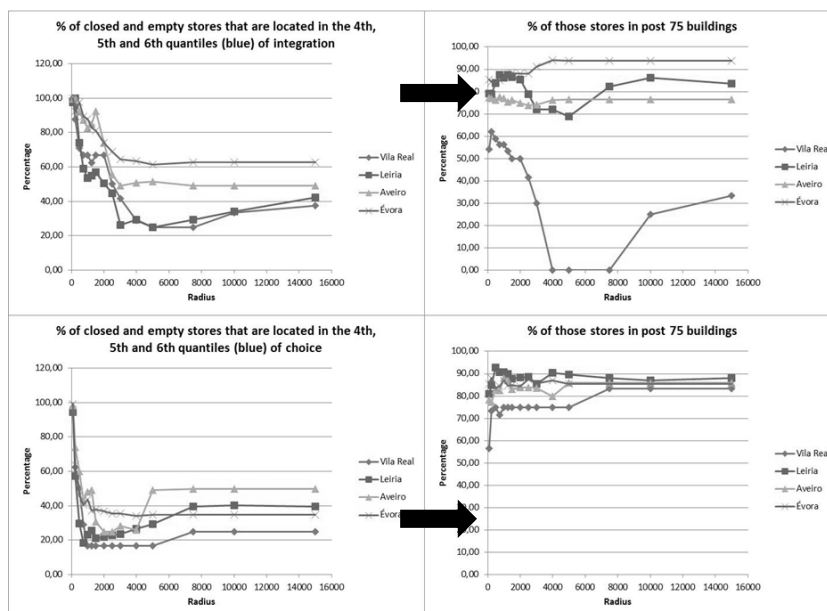

Figure 6. Percentage of closed and empty stores, in the peripheries, located in segregated lines, both for 'choice' and 'integration', and the respective percentage in post 1975 buildings.

Likewise, when Sarma (2006) reveals that MC, C and S categories (see footnote 2) do not correlate with 'choice', he grounds this statement on the analysis of a central location. In the case-study peripheries, for example, C stores are, logically, in travel-through thoroughfares and segregated out-of-the-way areas, and S stores, because they require space and have strong attraction by themselves, can locate just outside the centre in areas with limited attraction. As well, in the centres, even though M2 and MC stores have a strong affinity to first quantile segments, both of choice and integration, first necessity M1 stores obviously drift towards segregated (residential) neighbourhoods.

Concluding remarks

By combining, in four medium size cities, several morphological and commercial characteristics of stores and of the buildings, streets, blocks and neighbourhoods they are in, this research has established a link between the form and structure of cities and the commercial landscapes they possess. Actually, there is evidence that cities or city areas with more morphological (rather than statistical) similarities will have, on the micro-scale, more commercial similarities, something which strengthens the validity of what we called the 'morphological sense' of commerce. Based on the similarities between case studies, some reference-values were established and we found that the location, characteristics and performance of commercial spaces is to a significant extent connected to the following six aspects: (i) the amount, type and age of buildings and their distribution; (ii) the location of residential areas and whether they have commercial rows or not; (iii) the way urban hierarchies are structured; (iv) the configuration / form of the localities, that is, the structure of their blocks and of their street networks; (v) the relative position of the centres inside the localities; and (vi) the way localities / areas are connected through urban ribbons.

Nevertheless, the above commercial spaces features are not exclusively dependent upon these aspects. Because the store is intrinsically connected to the building it is in, it is almost impossible to state undoubtedly that the proven influence on a given area's development, residential growth or degree of centrality is caused exclusively by the store and not by, for example, any of the other uses a given building accommodates, or even by the mere existence of the building (or the street) itself. But the truth is the store is indeed there, it is open to the public and it is more directly entwined with the economic, social and morphological realm of the area it belongs than any other residential or service use the building might contain.

Therefore, the store is not only an economic motor and a wealth-generator, but also a city maker. It can produce centralities and friendly public spaces, and can command the location of new neighbourhoods and of new streets. Consequently, it can influence, among others, demographic and social indicators. In other words, commerce can indeed be an instrument of urban planning. With this in mind, the permissiveness of construction in general and of licensing of commercial establishments in particular could be substituted by a more comprehensive and demanding vision that would ultimately be much more beneficial to urban spaces. The similar thresholds found in our research can, for example, at least for cities of the same type, safeguard the construction of unnecessary store spaces (and hence avoid the scenario of empty stores), show excesses or deficiencies of a particular activity in a particular area, or regulate the construction of peripheral commercial poles, placing them close to a 'choice' thoroughfare, for example, to maximize the influence range of the stores therein. If there has not been a planning for commerce (Guy, 1994; Fernandes et al, 2000) but just a global planning that mentions commerce occasionally (Borchert, 1998), then looking at commerce from an urban morphology perspective can supply the necessary knowledge to start doing just that. Fuller (cit in Ratti, 2004) said 'reform the environment, stop trying to reform the people. They will reform themselves if the environment is right'. If, substituting the word 'people' for the word 'shop', the sentence still makes sense, then this way of thinking, as well, makes sense.

The systemic focus on walkability and urban form

Ana Paula Barros

PhD Student of the Department of Civil and Environment Engineering, University of Brasilia (UnB – Brasilia/Brazil) and of the Department of Civil Engineering and Architecture, Superior Technical Institute (IST – Lisbon/Portugal).
E-mail: anapaulabgb@gmail.com

Abstract. *This paper aims at analyzing walkability – most commonly approached in the studies of Transport Engineering – and the urban form – traditionally applied to research in the field of Architecture – in order to discuss the interdependence between both perspectives. The research is based on systemic thinking (relational) (cf. Capra (2003); Morin (2010); Bertalanffy (2012); (Vasconcellos, 2013)), in order to articulate different areas of knowledge for a more coherent reading of urban dynamics. In order to accomplish that, a thorough review and analysis of the literature about walkability and urban form was carried out, encompassing different areas of knowledge: geography, history, sociology, philosophy, literature, anthropology, architecture, engineering, medicine, etc. It was possible to verify that although each one of those fields reach the same diagnosis – there is a need for prioritizing pedestrian space –, the different fields hardly ever exchange information, which leads to fragmented interpretations. Thus, we suggest that the qualitative and quantitative approaches be merged, in order to effectively enhance the analysis, making it more sound and befitting to the reality of the object under study.*

Key Words: systemic theory, multidisciplinary, urban form, walkability, Space Syntax.

Introduction

Until the mid 20th century, the perspective of separating knowledge into specific fields implied the study of objects and phenomena in isolated approaches. Although consistent with a detailed research, the notion of fractioning in order to understand ended up masking a set of interdependence relations between objects, which compromised their interpretation. From the 1960s on, however, a new tendency arose: the trend of understanding the objects (or phenomena) from different perspectives, relying on a broader and systemic view (Capra, 2003; Morin, 2010; Bertalanffy, 2012; Vasconcellos, 2013).

It is under this paradigm that the present research explores the theme of walkability, in order to contribute methodologically to the debate, analyzing different field of knowledge to understand how the phenomena can be seen by distinct perspectives.

Walkability is approached from the standpoint of philosophy, social sciences such as anthropology, sociology and anthropology, health sciences (medicine and psychology) and engineering, thus encompassing both the qualitative and quantitative perspectives.

The emphasis in aspects of the constructed form can also be an important variable, contributing for different fields of knowledge. Hence, the facets studied by Space Syntax are relevant for both the quantitative and qualitative contexts, and provide a sound methodological contribution to the research at hand.

Theoretical background

Systemic thinking

The notions of relation and fragment lead us to consider the city as an entity or a whole, where articulations are formed and parts organize themselves, helping us to understand it as a system.

According to Cunha (1997), a system is a set of elements, materials or ideas, amongst which one can find or define some relation, method or process; and Alexander (1966) states that a system is a set of elements that belong together or work together somehow.

When viewed as a system, the city is a whole that includes relations of interdependence which cannot be perceived only by analyzing its components, and that is not consistent with an analytical perspective. Systemic thinking also implicate creating relations between different fields of knowledge, seeking connections between them. In urbanism, it corresponds to looking at the object of study – the city – from a set of perspectives that must invariably be articulated.

For Morin (2010), “there is an increasingly broader, deeper and more serious inadequacy between knowledge that is separate, fragmented and compartmentalized in disciplines and realities and problems that are increasingly more multidisciplinary, transversal, multidimensional, transnational, global, planetary”.

In fact, hyperspecialization hinders a global vision (which is fragmented in parts), as well as the essential (which becomes diluted). Essential problems can never be fragmented and the global problems are increasingly more essential. Moreover, all particular problems can only be placed in a planetary context (Morin 2010).

The relevance of a relational view gained visibility during the 20th century with the studies carried out by Bertalanffy (2012), in which he presents numerous applications of the systemic perspective in several areas of knowledge (politics, sociology, psychology, psychiatry, medicine, physics, computer science, military, biology, amongst others). The author believes that “it is a transformation in the basic categories of thinking of which the complexities of modern technology are just one – and possibly not the most important – manifestation. In one way or another, we are forced to deal with complexities, with ‘holism’ or ‘systems’ in every field of knowledge. This implies a fundamental re-orientation of scientific thinking”.

The contemporary re-orientation of science considers researching a way of articulating knowledges and disciplines, in addition to understanding the object as something related and interdependent. According to Bertalanffy (2012), “[...] the only way to study an organization is to see it as a system, once the systems analysis treats the organization as a mutually dependent system of variables”.

The trend to study systems as an entity and not as a set of parts is in line with a trend in contemporary science that no longer isolates the phenomena in strict confined contexts; instead, it is open to the study of interactions and researches increasingly broader sectors of nature (Ackoff, 1960 apud Bertalanffy, 2012, pp. 29).

From this standpoint, Medeiros (2006) “considers that there are characteristics of the whole that cannot be understood by the sum of its parts: they exist only when the parts of the whole act and arrange themselves relationally.

Thus city, mobility and walkability must be understood as parts of several articulated fields. Moreover, it is paramount to study the relations between the elements that compose the city, such as the urban form, because they contain the perspectives to explain the phenomenon.

It is important to highlight that, in order to apply systemic thinking it is necessary, first and foremost, to be ready to change the paradigm. Vasconcellos (2013) believes, for example, that “systemic thinking is the new paradigm of science”. A paradigm is the way we perceive the world and act towards it, based on our own rules. The author also warns us about the fact that “when our paradigm becomes ‘the paradigm’, the only way to view the world and act, a dysfunction called ‘paradigm paralysis’ or ‘fatal certainty disorder’ takes place” Vasconcellos (2013).

The ‘*paradigm paralysis*’ can stop us from seeing opportunities that are all around us in several situations. In order to recognize and enjoy these opportunities, we need to be flexible and willing to embrace new views, different from what we are used to. “In addition, the changes in paradigm can only occur through experience and evidence that places us face to face with the limits of our current paradigm” Vasconcellos (2013)

How is it possible to use this approach of a changing paradigm to understand walkability? The first step seems to be the need of increasing the knowledge about walkability from several angles, which would provide input to understand the city and its form.

Walkability

In Portuguese, the verb ‘walk’ is “caminhar” which derives from “caminho”, a word that means ‘path’. As well as in other Latin languages such as Italian, Spanish, and Catalan, it has the meaning of following a path, a road.

Moreover, we must take into account how often the act of walking is referred to in the non-scientific literature, which shows how present it is in the life of individuals as a symbol of human life itself. The Italian writer Ítalo Calvino explored the description of imaginary villages, in his work *Invisible Cities*, where the importance of walking to the perception of the urban space is poetically presented. For Calvino’s traveler what matters is the act of walking in itself, not the crossing of space by other vehicles: walking expresses a vigorous relation with the space.

This is the same philosophy that guides the work of authors who claim that walking is crucial for understanding the world. Canellas (2013), in a series of chronicles, translates the importance of walking for the comprehension of the urban space (something which would not be possible by car). Reading the city becomes easier when we cross its distances on foot.

People ‘feel’ the city in a different way when walking, instead of travelling in the high speed of cars. Although everyone is a pedestrian at one time or another, we choose the car in most occasions, even if the result is a distance from other people and from the city. Acceleration and swiftness matter most, because this concept is embedded in the western imaginary as a positive paradigm: there is no time to waste (Gondim, 2014).

From a philosophical standpoint, in the view of Solnit (2001), walking allows us to get to know the world with body and soul, being an important cognitive experience in a time when individuals prioritize the use of car in their displacements.

Walking the streets is what connects the reading of a map with life, the personal microcosmos with the public macrocosmos; it is what grants order to the surrounding labyrinth.

There is also a belief that walking involves a process of self awareness, and maybe even inspiration. Gros (2010), based on the text *Ecce Homo* by Nietzsche, highlights the importance of walking in the professional life of the philosopher, stating that for Nietzsche “a walk outside was an element of his work, the permanent follow up to his writing”. He adds that Jean-Jacques Rousseau, in his work *Mon Portrait*, stated that only when he walked he was able to think, compose, create and feel inspired.

In *Éloge de la marche*, published in 2000, the anthropologist and sociologist Le Breton discussed the relevance of walking for human relations, for life. He attests the relevance for urban mobility and criticizes the overdependence on the use of car in contemporary days.

Considering the excerpts presented, it is clear the interpretation that walking is also seen as a path for comprehending the city and even the individual. From a philosophical or artistic standpoint, walking is the element for understanding and decoding the outside world, somehow a counterpoint to a time that overvalues speed and swiftness. The increasing value placed on the vehicles means a devaluation of the act of walking, which becomes a symbol of something outdated. However, there are indications that say the opposite: walking is the permanence of time and the path to a clearer vision of what the city and the world around us really are.

Urban Form

After what was discussed above, it is possible to assume that the act of walking favors a coherent understanding and experience of the city, for reasons embedded in different fields of knowledge. Walking in the city can be interpreted in terms of origins and destination, or in terms of the capacity of places becoming routes or points of arrival, as discussed by Hillier

(2008). There seems to be a logic in the organization of urban spaces that affects the process of choosing paths, which expresses the preferences of individuals for a certain path or another.

Speaking about organization of space means considering the urban structure, perceived as a system of interdependences and understanding how the form of the city influences the act of walking. This component may play a more relevant role than previously imagined, actively conditioning the flow of pedestrians.

According to Cunha (1997), form encompasses “the way in which something exists or manifests itself, configuration, outer appearance”. Urban form is understood as geometric composition of the elements of a city (streets, buildings, blocks, facades, street furniture, vegetation, etc.), its dimensions and proportions (geometric scope). Moreover, it is of interest to examine how the elements of the urban space are placed and how they relate to one another, in a bidimensional or tridimensional perspective. Since these relations are relevant and result in hierarhical variations, we intend to draft a topological reading (topological scope).

In the literature, urban form has been historically dealt with in terms of its differences in layout. In his work *Wanderlust: a history of walking*, Solnit (2001) poetically and accurately portrays the distinction between the traditional urban form (cohesive) – or pre-modern (Holanda, 2013) – and contemporary (isolated) – post-modern (Holanda, 2013).

The polarization of spaces between isolated and cohesive is in line with the notion of fraction and relation that are the heart of this research. To a certain extent, the isolated spaces become the fragments of a larger space; whereas when these spaces are cohesive, they create an environment which is better articulated to the whole urban system.

Polarization is recurrent in the interpretation of patterns of urban form in cities throughout history. Here, it is a tradition to analyze the layout of the urban grid as a symbol of the city form, one of the most emblematic and long lasting features of urban structures. In the opinion of Kostof (1992); Kostof (2001), there are two main kinds of urban form: the irregular/organic and the regular/grid/orthogonal/chessboard. However, for the author, the cities are not rigidly composed: they are a mixture between regularity and irregularity. In present times, one would hardly be able to achieve a homogenous layout that spreads all throughout the city.

When discussing the issue, Medeiros (2006) emphasizes the same kinds mentioned by Kostof (1992); Kostof (2001), when analyzing a sample of cities in Brazilian and around the world. However, when analyzing the articulation between the layout and the impact they have on displacements, the author highlights that the issue is not the existence of one type or another, but how they are articulated. Aspects of seaming, connection and relations between the various axes seem to be more relevant than the layout itself. The quilt pattern urban forms are regarded as the most negative scenarios for urban mobility, even from the perspective of walking: the apparent planning seen in the regularity of the layout disappears for a lack of global intention that could foresee coherent levels of integration amongst the parts.

In order to understand form, one must simultaneously understand geometric and topological aspects, with the focus on relations, on the articulation of the elements of the city. This interpretation seems to play a substantial role in an individual's process of displacement in space.

Different views on the paradox cars vs. pedestrians

The theme of mobility is present in several fields because it is one of the most relevant aspects of the urban context, especially considering the crisis cities have been going through and the need for a better displacement in order to ensure the vitality of the settlements. As Gehl (2010) states, everybody needs to move around space in order to carry out their daily, weekly or monthly chores. In order to achieve that, everyone start their trip in a point of origin A to reach their destination B, using some mean of transportation. It may be individual public transportation (taxi) or group public transportation (busses, trains, subway etc), individual motorized transportation (car or motorcycle) or non-motorized transport (bycicle or walking).

As displacements are essential to urban life, attention to the paths taken is paramount: Jacobs (2001) defines the street and the sidewalks as the main public places in a city. The research about the structure of these paths has received an increasing number of converts, which progressively raises attention about the relationship between the quality of space and performance of displacements.

It is remarkable the protagonist role the individual motorized vehicles in the use of urban space. Although walkability has been the focus of studies both from the area of Transport Engineering and related disciplines, it has not yet gained enough visibility to convince society of its relevant and determining role in fostering more people friendly and functional spaces.

There are several studies showing that cars take precedence over pedestrians in the context of urban mobility sometimes present in more descriptive or more analytic discourses, with references to them present in several fields.

The diachronic scrutiny of the topic shows a shifting preference for either qualitative or quantitative contexts, depending on the field that is undertaking the analysis. In the first, we can verify the main presence of the discourse, many times connected to the artistic, poetic or philosophical scope. Here the incorporation of the evaluative aspect of the narratives happens, with the purpose of bringing together the philosophical scope and the empirical information obtained. In the second, the purpose is to transform what is observed in the urban practice into numeric models, bringing together statistical aspects that strengthen the analysis.

In order to foster the understanding of both aspects and their corresponding strategies of approaching the topic, we present the views of authors from several fields of knowledge that mention aspects of mobility in the city.

Qualitative context

In the field of sociology, as far back as the 60s, it is possible to see that Lefebvre (1968) already associated the image of the car to something that could compromise the good development of the city, which to a certain extent already defined a criticism to industrial society.

The idea that, in addition to its symbolic features, the car hinders interpersonal relations and thus the use of public space is also highlighted in the area of anthropology. The observation made by Caiafa (2007) is accurate in certifying that the public investment is focussed predominantly in favor of motorized vehicles, with the implementation of more roads and overpasses to accommodate the flow of cars, ignoring pedestrian traffic (Caiafa (2002).

The focus, however, should be on diversity, and not on prioritizing one mean of displacement to the detriment of the others. Caiafa (2007) adds the notion that the public space, when occupied by people, is transformed in a heterogeneous environment in which people mingle with strangers. The author concludes saying that “the urban experience is strongly supported in the creation of this collectively shared space of contact [...] In the streets of the city, when they are used by the public, we experience a great variety of stimuli, such as the great human diversity to which we are exposed” (Caiafa, 2007).

Together, the sociologic and anthropologic views take into account the individual and their relations to one another and with the world. Therefore, mobility plays a fundamental role in this interaction and here the car represents individualism and exclusion.

In the field of geography, Yázigi (2000) presents his contribution to understanding the city and its inhabitants, by studying the sidewalks. The author places the sidewalk in the diachronic context when interpreting the past, present and future, presented under a historic discursive character, highlighting its role of inclusion/exclusion in society.

Cardoso (2007) and Affonso (2012) explore the role played by transport in aspects of social inclusion/exclusion, and he observes that the automobile takes precedence over the pedestrian, even if their findings are not articulated to other areas of knowledge.

Under the perspective of history, Barros (2007) believes that the role of pedestrians in the city remains unaltered at all times, according to a research in which he gathers information from

history, sociology and urbanism. For the author, a person who walks experiences a variety of sensory information.

There is also a growing tendency of studying the theme from an interdisciplinary perspective, similar to what was developed by Yázigi (2000) and Gondim (2014), who unite historical aspects of the city and urban mobility, with the intention of identifying symbolic permanence of the paradigms of high and low velocity throughout time. The author concludes that the vehicles, even when non-motorized, take precedence over pedestrians in the urbis since time immemorial, and that the problems related to the conflict pedestrians/vehicles are not new as many tend to believe.

The research carried out by Steg (2005) – a classic from Psychology – deserves to be highlighted. It articulates qualitative and quantitative perspectives, and it proves through statistical data and the application of questionnaires, the power that the car exercises over people. It concludes that people do not drive only because it is necessary, but also because they love to. The symbolic and affective aspects contribute significantly for the positive use of driving and this may be one of the reasons why there is such a great resistance to the policies for reducing the use of cars.

Quantitative context

Similar to the research made by Steg (2005), there are research strategies that try to bring together qualitative and quantitative aspects, discourse and numbers. In architecture and in this research in particular, we pay special attention to the syntactic approach focused on walkability.

Initially, it is important to cite the research of Rodríguez (2007) that approaches displacement and mobility relations through the analysis of syntactic and social variables. The author highlights the priority given to the individual motorized vehicle. The findings suggest that the quality of spaces destined to pedestrians is below the expectations, which does not encourage walking.

Mehta (2008) produced an empirical and qualitative study about the relation between walking and the physical aspects of space, land use and the social features of the environment in microscale. In the study, people's behavior was measured through countings and the perception of people through questionnaires. As a result, it was possible to verify that the great majority prefer spaces with a variety of uses, the presence of shops, activities and people.

The research of Tenório (2012) is based on the premise established by Jacobs (2001), Whyte (2009) and Gehl (2010) about the morphological characteristics of the space and its impact to urban vitality. The author explores the excessive preference given to individual motorized transportation and, therefore, the little attention paid to non-motorized ones. The study used pedestrian countings and interviews as a research tools and in addition the author proposes a method to the evaluation of public space that is based on empirical verification (qualitative analysis) and does not focus on quantitative aspects.

The studies of Choi and Sayyar (2012) and Choi (2013), although considered simultaneously qualitative and quantitative, are based on data from the software of syntactic analysis. There are no relational statistical interpretations, therefore, the modeling of data is considered basic for the standards of Transport Engineering. The studies analyse the data of diversity of land use, population density, syntactic analysis and pedestrian behavior in three neighborhoods with different urban layouts. The results obtained show a strong correlation between morphological and syntactic typologies and the convergence with diversity of land use, which corroborates that the form fosters movement and, therefore, fosters the presence of attractive factors.

Wineman *et al.* (2012) explore the correlation between the characteristics of the built environment and the data for physical activities (here understood as walking with the purpose of displacement). From the results obtained, it was possible to verify that the people who live in more integrated neighborhoods report higher levels of physical activity if compared to the people who live in less integrated ones. Moreover, people who live in neighborhoods with high local connectivity report higher levels of physical activities, in contrast with people living in

low local connectivity areas. In general terms, the findings show that when a neighborhood is well connected locally and globally, they present high density with a heterogeneous mixture of land use and are associated to higher levels of localized physical activities.

The work of Ozer and Kubat (2013) aims at predicting walkability more precisely by comparing the spatial syntactic measures with the measures of environmental and pedestrian perception, in order to check their effects over the level of displacements on foot. They used pedestrian countings, spatial configuration data and questionnaires about the perception of urban environment. Later, they drafted a statical correlation between the number of people (counting) and the integration data (syntactic). The findings reinforce the potential of the data gathered from the syntactic analysis of space, because depending on the other variables, there may or may not be an encouragement to walkability.

It is thus important to highlight that the approaches mentioned above explore either the discourse in itself (discursive-qualitative context) (exception to the work of Steg, 2005) or the discourse aligned with the evaluative process, both related to the qualitative analysis. The evaluation, sometimes (when Space Syntax is used), is closer to the more quantitative interpretations, although it still lacks the soundness present in Transport Engineering.

Qualitative Context

When studying pedestrians, it is an essential condition to know the detailed aspects about the environment where the traffic flows. To this end, the qualitative works that focus on the characterization and evaluation of the environment of walking are presented.

In this topic we aim to examine works of two areas, Medicine and Transport Engineering, with focus on walkability, approaching aspects of the urban form. The first one focuses on (a) statistical data regarding diseases (obesity, diabetes, heart problems, etc), (b) daily physical activities (in the case of walking, referring to daily displacements), and (c) characteristics of the built environment (from physical aspects or urban layout to the different composition of street grids, disregarding those not related to the syntactic/morphologic aspects). The second research focuses on the aspects of the built environment (urban form), mixed uses, population density and data about mobility.

In the context of health, there seems to be continuity in the studies that try to find a pattern in walkability related to aspects of the built environment. There is a number of works that adopt different analytic strategies, such as: Owen *et al.* (2004) uses aesthetic and infrastructure aspects; Leslie *et al.* (2005) which is based on the study of neighborhood with different layouts; Frank *et al.* (2005) that furthers the discussion including the use of equipment to measure walking speed; Giles-Corti *et al.* (2006) who uses questionnaires as the main strategy; Leslie *et al.* (2007) who gathers the data about uses, street layout and socio-economic information in the SIG platform; and finally Grant *et al.* (2010) whose focus is on the elderly.

The works from researches Frank and Pivo (1994), Handy (1996a), Handy (1996b), Cervero and Kockelman (1997), Amâncio (2005), Reid and Cervero (2010) and Rodrigues (2013) seek to learn to what extent the aspects of urban form interfere in walkability. In order to do that, the methodology used varies, correlating data from transportation with socio-economic and activities, using questionnaires and countings, and incorporating data about the urban network (using or not the SIG platform). It is interesting to observe that although these researches study urban form, they do so mostly from the geometric perspective, and only in some cases include topologic aspects. Even in the case where the topologic perspective is taken into account this is done from a Cartesian perspective, and not from a systemic one.

Methodological contribution

As discussed previously, the systemic perspective applied to urban mobility leads to the research of the relations between the elements of the city, expressing a dynamic between the global and local scales.

In the global scope of this research, we aim to consider systemic thinking based on the analysis supported by two interpretations: (a) the qualitative context and (b) the quantitative context. The articulation between both would allow bringing together the dimension of architecture and transport engineering in order to understand walkability.

According to Van der Maren (1985 *apud* Lessard-Hébert, 2012) there are clear distinctions between the two perspectives, qualitative and quantitative. In the first, the processes have an speculative nature, whereas in the latter they are more experimental. Thus, it is possible to reach a broader view of walkability when we bring together perspectives from different areas of knowledge, such as those described above, which is the end goal of this research.

The understanding of this connection between qualitative/quantitative approaches is prioritized in the interpretation offered by Space Syntax, in which the research of the relations between the void and the constructed areas is of special interest, which encompasses configuration issues.

Hillier (2005) states that there is a great problem remaining in the studies of urban settlements, since the city is still thought as either a social entity or a physical one, with social scientists specially dedicated to the study of the first, and architects to the latter. What seems to be missing is the connection or a 'bridge' and he claims that "historically, the main goal of Space Syntax was to build a bridge between the human city and the physical city".

The approach, however, is usually criticized by those outside its traditional circles of application. Some critics point to the excess of quantifications (cf. Medeiros, 2013); and others they claim that those statistics are shallow, as stated by Maha (1997) and Alves (1999).

Nevertheless, Barros (2006) responds to such criticism by demonstrating that the analytic perspective of Space Syntax is useful for research about urban mobility. The author has found meaningful values (61%) in the correlation between real flow counted by electronic equipment in the streets of Brasilia and the so called integration indexes from Space Syntax).

Therefore, Space Syntax was chosen for the research, both in the local and global scopes, in order to establish a connection between the qualitative and quantitative aspects, enabling a broader analysis of the object under study: walkability in cities (Figure 1).

Figure 1. Relation between global vs local aspects from the standpoint of systemic thinking, portraying the role of Space Syntax.

Final Considerations

Based on the discussions presented in favor of a comprehensive analysis of the qualitative and quantitative aspects (local), it is possible to reach more detailed information about the object of study. Different perspectives about the object of study, gathered from several areas of knowledge allows a more detailed analysis, thus incorporating a broader view of a system, that is, systemic thinking.

According to what was explored in the research, by bringing together the two strategies it was possible to notice the relevance of Space Syntax, understood as a potential bridge between Architecture and Engineering.

Although there are other theories that allow this connection, in the particular case of this research – focused on urban form – this is the one that best fits the purpose, due to the configurational aspect of the theory, closely related to urban mobility and, thus, to walkability.

Therefore, it is possible to notice that this contribution to the methodology allows us to broaden our scientific horizon, by making the connection between these areas of study tighter, which can in turn contribute to the creation of policies for fostering mobility in cities.

Abstract. *Streets, avenues, boulevards, lanes ... innumerable are the public spaces designated to the circulations of cars and pedestrians; in fact, the opens spaces work as a system and are represented by many typologies that gave form to the city. Brazilian cities, as a rule, have being building open public spaces as if they were residual spaces of private properties. Public policies promote facilities to car owners, so pedestrian circulation was reduced to spaces with little functionality (locomotion, access conditions, shape, dimensions and other morphological attributes), that resulted in places of public life that do not guarantee the quality or safety of the users. São Paulo's mater plan has been suffering numerous amendments to promote a better mobility without the presentation of studies pertaining to pedestrian spaces sidewalks. The actions of the public authorities to the issues about urban mobility have been reduced to the deployment of public transport with a focus on buses. Issues such as quality of driveways (one-third of the trips in the city are made on foot), safety against the set of barriers (equipment, public securities and urban infrastructures) randomly distributed in space, private management (the responsibility of management of sidewalks is of the owner of the immediate area) generate the need for indicators to cooperate not only on qualification of existing spaces as well as in organizing projects guidelines to cities in expansion process.*

Key Words: urban form, urban mobility, walkability, open spaces system, landscape architecture

Introduction

This text is part of the research called planning, design and management of the the Master (professional degree) program on City Planning called Project, Production and Management of Urban Space. The master's degree enables graduates to serve areas directly linked to the world of work and future production system. Empowers and trains researchers and professionals to generate, disseminate and use scientific knowledge in their daily work.

The knowledge is collected and organized from the observation of reality that leads to reflection, analysis and review of routines and processes generating solutions to noted problems. The surveys shown are part of a research that studies urban mobility, with focus on walking journeys made in Brazilian capitals. In the text, we present the situation found on some sidewalks of the city of São Paulo.

Far more than simple pathways

Far beyond its function of making possible the movement of people between different places from urban areas, the sidewalks are places of sightseeing and "tour". From this linear space, the citizen can contemplate the open public space, the buildings that make up the landscape, the movement of people, feel the sun and the wind, and enjoy the plazas and gardens. Live the urban life.

Connected to the road network of the city, the sidewalks are conected physically to the streets. Street that play distinct functions in the circulation, transport and mobility system functions of contemporary cities.

A question arises: but how the public footpath became bound to the secondary road network route?

About the fragmentation of sidewalks and public tours: the lack of unity in the design

We assume that it is possible to qualify the level of civility of a place from the pavement morphology, maintenance, coating, location, lighting ... in other words, applied to aesthetic standards and the efficient displacement of the pedestrian into a functional city.

The sidewalks along with all the types of public open spaces accounts for up to 40% of the areas found in Brazilian cities. They are squares, parks, beaches, public gardens, streets, avenues, they are also part of the space for the citizen. In Brazil, the public space was born as a heritage of the founding of cities: either by donations, expropriation or legal obligations to the land allotment, the truth is that these spaces were born as leftovers, waste from the private sphere life.

Culturally, the way in which spaces for public life or *res publica* were created, is key to understanding the popular culture: public space is not from or to the public that attends. Therefore, it is an "unknown" whether the municipality or the owner of the establishment must ensure their construction quality and maintenance.

Despite the National Traffic Laws consider sidewalks as part of the public highway and therefore responsibilities are due to government, is up to the citizen its maintenance. This kind of "strange" culture also permeates the actions of government.

Rather than take responsibility for public space, the city of São Paulo transfers the responsibility for the construction, reform and maintenance services to homeowners and to renters who can be fined if the sidewalks do not meet Decree No. 45,904 of May 19, 2005.

The government ignores that the sidewalks integrate a system of broader circulation over the city that also incorporates streets where vehicles travel. To blame the homeowner, the city manager acts as if this system were the sum of excerpts interrupted and fragmented by steps, plants, benches and so on, without pattern coating, design and construction guides.

The quality of the public footpath is compromised and directly reflects the welfare and safety of citizens. Origin-Destination Survey taken by the São Paulo Metro in 2011 showed that 30% of the daily trips in the metropolitan region of São Paulo (which encompasses 39 counties and nearly 20 million residents) are realized on foot in approximately 23 million daily trips.

The decree defines a new architectural standard for city sidewalks. It establishes standards to ensure accessibility and the materials that can be used. It also adds that the sidewalks should be divided by service groups. They are:

1) Area destined to public services: with minimum recommended width of 0.75 m, is the closest to street "strip", for the placement of trees, access ramps for handicapped vehicles, lampposts, traffic signs, benches, planters, telephones, mailboxes and trash cans.

2) Open area strip: with a minimum width of 1.20 m, is intended exclusively for pedestrian circulation and thus should be free of any height differences.

3) Area strip of access (no width): existing only in pathways which are greater than 2 meters wide, and located right in front of the property, it can contain tables, vegetation, sunblinds, ramps or advertisement, since they do not impede access to property.

The pavement should be divided into groups differentiated by texture and / or color, according to its width:

- Sidewalks with up to 2 meters breadth: should be divided into two areas
- Sidewalks over 2 meters breadth: should be divided into three groups

What follows are some images that illustrate the situations encountered in all Brazilian cities.

Planting on sidewalks: the yard invades the street

The planting of vegetal species varying between ground covers and Flowering Trees is a cultural habit in all Brazilian houses. Fruit trees such as blueberries, mango and coffee trees are common in city streets. They are planted by citizens both, in their yards and in front of their homes. When in apartments, balconies are full of large vessels that have lemon groves, jabuticaba trees and orchards. The problem is that ordinary people plant these elements inappropriately without knowing the consequences of aggressive roots, trunks, branches and flowers can cause to the pedestrian safety and to maintenance of sidewalks.

Figure 1. Home yard and outside space planted in the same way (source: Pamela Silva, 2014).

About the widths of sidewalks: coexistence is not always possible

Since the creation of the streets was an act of donation of land or public expropriation, the movement of pedestrians and freight transport occurred spontaneously as from the absence of the state in defining a plan of action to discipline mobility. It is natural therefore that there is no hierarchy on streets, there are no appropriate width or places to for maneuvers or also not permitting a flow of pedestrians (in densely populated areas) safely.

Figure 2. Streets and narrow sidewalks (source: Pamela Silva, 2014).

Figure 3. Streets and narrow sidewalks (source: Pamela Silva, 2014).

About the differences between levels: the sidewalk as an extension of the house

To adapt the external access to domestic areas of buildings, the level difference between street, sidewalk and private property, ramps are built. Regardless of the width of the sidewalk or the height differences, instead of remedying the situation inside the property, public area is transformed into a house extension. Solved the problem of access for residents and the car in front of the house, the problem of the staircases created by ingenious solution remains to pedestrians.

Figure 4. Adequacy of public sidewalk for access of the residence (source: Pamela Silva, 2014).

Pathways: materials and finishing coats to suit all aesthetic tastes

The illustrations bellow show common situations in everyday life of the city. The use of materials for coating the pathways happen according to the aesthetic taste of the owner of the property and independent of the length of it. The maintenance, the owner's responsibility and depends on the availability of time and financial resources of the same.

Figure 5. (source: Pamela Silva 2014).

Figure 6. The sidewalk in front of a vertical condominium, although narrow to existing legislation, allows a peaceful transition without "scares" When materials are chosen and the ride is executed correctly, the maintenance is easier. (source: Pamela Silva 2014).

Urban Furniture: what is for the sidewalk?

The government also acts out of the public laws, although imposing the same law private owners. Maintenance is careless when it exists. In the research, it was found that there were about five dozen agents that intervene directly on the space of sidewalks. Among them we find companies that have a "concession" to the operation of a public service and those who have the "permission".

"Concession" means the transference to perform a public service by contract service to private owners companies for a specified period. This is a long term, beyond decades.

As "permission" means a precarious administrative act by which the Government transfers the running of public services to private owners companies. In this case, the instability is in fact that permission can be revoked at any time without the need for payment of compensation by the municipal government to that which was allowed.

The difference between both is the compensation for cancellation of public contract as well as the definition of term.

From the perspective of what has been presented in this paper, there were found in searches many inappropriate situations on dealing the public space.

Figure 7. tables, chairs, coffee and beggars. Where is sidewalk? (source: Helena Degreas, 2014).

Public facilities: fits so much?

Figure 8. Poles, newsstands, bus stops, metro access via escalators. The lack of space for pedestrian walkability leads pedestrians to use the street to walk over the city. (source: Paloma Lopes 2014).

Some thoughts on the topic: The public space can satisfy the public who goes to public space?

A comment is necessary: the definition of groups/strips of service is an excellent solution to the problem since the sidewalks of the city arose spontaneously and so alien to urban legislation. As a consequence they have no shapes, proportions, width suitable for vehicular routes system which physically connect them.

It is possible that the idealized management (generic) embedded in the legislation will solve the problem or may bear some application in order to help organize new environments created on the sidewalks?

Perhaps by analyzing each case separately the distribution, location of furniture and equipment may actually be helpful to the citizen and no longer a barrier that hinders accessibility.

There are two problems that need to be addressed by the city if the aim is to create conditions of comfort and safety to citizens:

- The width of the sidewalks in the central regions of São Paulo does not reach 1.50 m. In peripheral regions the sidewalks behave the much the lamppost. In many cases, it does not exist. Because public housing policies for centuries were not the object of interest of various municipal administrations, the city was randomly constructed and outside urban law. . This created numerous neighborhoods where urban infrastructure is precarious, public facilities for health, education, security, leisure, transportation is inadequate. As part of the infrastructure, sidewalks also suffer from the same problems.

- The different actors (licensees and concessionaires) that interfere in public space, especially on the sidewalks, are numerous. Existing legislation only refers to those who legally respond to the municipality as an example owners of bars and restaurants that want to put tables on the sidewalks, or even shopkeepers who put benches in front of the store or the citizen who intends to plant a tree in front of the his residence. Remember that agents are responsible for providing public services in different areas: municipal, state and federal. Requests for intervention in public space are also held in various "desks". The fragmentation of these departments and agencies in city is visible and materializes its interventions on the sidewalks.

The elements of urban morphology which influence residents' leisure walking activities: case study of Shanghai

Jie Mao, Yong Chen

College of Architecture and Urban Planning, Tongji University, No. 1239, Siping Road, Shanghai, 200092, P. R. China. E-mail: 231269952@qq.com, ch_yong2011@tongji.edu.cn

Abstract. *With the rapid development of motorization in modern cities, urban morphology is threatened seriously which gave priority to walking transportation before. It also leads to the changes of residents' walking characteristics. Leisure activities such as stroll, fitness and walk the dog increase significantly, but the essential commuter walking activities reduce gradually. In this research, 21 neighbourhoods were taken as cases to make questionnaires survey, observation on site and multiple regression analysis. Effectively statistic model was made to seek the key variables of urban morphology which influence leisure walking activities. It was found by the research that, objective variables of urban morphology affect the frequency of leisure walking more than subjective perceptions do, while the subjective perceptions of environment affect the duration of leisure walking more than objective variables do. Six variables of urban morphology have critical influence on the frequency of leisure walking. They are penetrability of sidewalk network, mixed land use, proportion of commercial interface in the street, density of the storefronts in commercial interface, wide space with hard pavements, safe and neat community environment. In addition, residents' individuality such as societal attributes and subjective demands have intrinsic influence on choices of leisure walking activities as well.*

Key Words: *Leisure walking activity, urban morphology, built environment, neighbourhood.*

Background

In recent years, many researches have attempted to enhance the cities' livability by improving the urban forms in the field of urban design. In the field of urban planning, the ideas of low-carbon city and green travel have been proposed. In the field of transportation planning, the concept of Non-motorized Traffic (NMT) has been put forward. As to the public health field, more physical activities and exercises have been encouraged. The common intersection point of these fields advocate more walking, and promote walking activities by built environment.

Many previous studies from North America and Europe held the views that it can increase the walkability of cities by intensive construction of land use, dense sidewalk network, more commercial facilities, or other measures (Frank and Pivo, 1995; Cervero and Kockelman, 1997; Greenwald and Boarnet, 2001; Moudon et al., 2006; Alfonzo et al., 2008). But some studies got the opposite conclusion (Crane and Crepeau, 1998; Handy and Clifton, 2001). The key factors of urban morphology founded out by these researches, which focus on their respective regions, were both similar and different. Meanwhile, are these researches suitable to develop in Asian countries? Especially to the emerging Chinese cities, their population density, economic level, cultures and customs are totally different from those regions.

With the improvement of living standard, Chinese residents pay more attention to their health. Leisure walking activities which take stroll, fitness or social contact as their purpose have been increased substantially. The demands of quality and quantity of walking spaces also have been increased. But, on the other hand, in the process of rapid urbanization and motorization, the construction of Chinese cities tends to provide convenient to private cars. Such construction mode has encroached pedestrian space seriously. Many form designs of neighborhoods never take the interests of walking activities into consideration. Therefore, how is the current situation of residents' outdoor leisure walking activities? What are the residents'

main demands of pedestrian environments? What kinds of space morphology factors in the neighborhoods will influence residents' leisure walking activities? These problems all need to be pondered.

Survey

Research objects

This study tries to find out which characteristics of urban morphology will make more important influence on residents' leisure walking behaviors, by quantization the characteristics of spatial morphology of neighborhoods. Moreover, residents' personal attributes and attitudes to walking will be also taken into consideration as influencing factors.

Urban Morphological Variables:

- i) Characteristics of spatial forms: including 6 aspects, they are neighborhood attribute, spatial texture, land use, public transit service, walking facility, interfacial morphology.
- ii) Satisfaction of subjective environment: refers to the individual perception and evaluation of the pedestrian environment, including 7 aspects, they are satisfaction of whole environment, satisfaction of accessibility of public transit, satisfaction of accessibility of commercial services, satisfaction of convenience of road network, satisfaction of traffic safety, satisfaction of security and satisfaction of quality.

Residents' Leisure Walk Behaviors - outdoor leisure activities, that residents make walking as their purpose, are calculated by two ways, frequency and duration:

- i) Walking frequency refers to the times of residents' leisure walking weekly.
- ii) Walking duration refers to the amount of residents' daily leisure walking.

Selected cases

Shanghai is one of the biggest cities in China, which has the highest population density and fastest pace of economic development. This study selected 21 neighborhoods in central urban area of Shanghai as cases. Each neighborhood is about 0.5 to 1 km². They are the units which can take 8-minutes' walking distance as their radius. And there is at least one subway station in or near the units. Make the main roads or river system as their boundary. According to the times of construction and characteristics of spatial morphology, they can be divided into 5 types (Figure 1): 1) historical neighborhood; 2) workers' village; 3) old neighborhood; 4) new neighborhood; 5) international neighborhood.

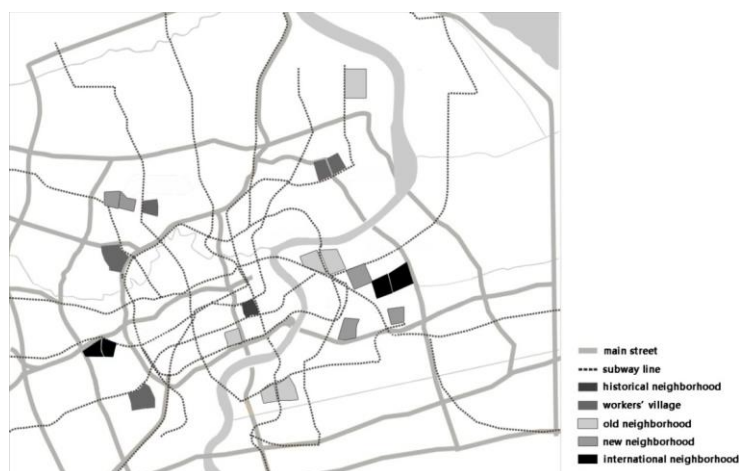

Figure 1 Distribution map of cases of neighborhoods.

Summary

During the period from December 2011 to June 2012, questionnaires were sent to those 21 neighborhoods and took back. The content involves the residents' social attributes, characteristics of outdoor walking, satisfactions about the pedestrian Environments, etc. The quantity of questionnaires for each neighborhood was determined on the basis of its population. Community service workers selected the households and made the survey at random. Totally, 3820 questionnaires were sent and 2940 questionnaires were taken back. After the evaluation of integrity and authenticity of each one, 2863 questionnaires were selected as the last samples. The rate of the useful questionnaires is 74.9%.

The results of the survey show that the average level of residents' daily leisure walking is 28 minutes. Furthermore, 41% of the residents have their daily leisure walk more than 30 minutes averagely. But, there are still 10.9% of the residents whose daily leisure walking time is almost zero. From the view of personal attributes (Figure 2): The older the resident is, the more he/she spent on leisure walking, especially for those who are tired. The aged over 70 is the group which has the most leisure walking activities. Their average level was 37 minutes. Primary and middle school students under the age of 19 is the group which has the least leisure walking activities. Their average level was 18 minutes. From the view of types of neighborhoods, average level of leisure walking is around 30 minutes in all kinds of neighborhoods. The residents in international neighborhood have the longest walking (29.6minutes), while the proportion of the residents who almost never have daily leisure walk in the workers' villages and the old neighborhoods, where blue-collar workers occupy the majority population, is highest (13%).

Figure 2. Leisure walking duration of different social groups.

Analysis and results

Correlation Analysis

Pearson linear correlation analyses on the data of residents' leisure walking, satisfactions of pedestrian Environment and the spatial morphology were made by SPSS statistical software to find out the variables which are related to leisure walking.

i) Residents' Satisfactions of Pedestrian Environment

Table 1 shows that the residents' satisfactions of pedestrian environment have more influence on their duration of leisure walking than on the frequency. Satisfaction of whole environment (0.079) correlates with residents' leisure walking duration most. And then, satisfaction of accessibility of public transit (0.062), satisfaction of accessibility of commercial services (0.060), satisfaction of convenience of road network (0.058). Satisfaction of traffic safety and Satisfaction of quality are the least two variables.

It can be inferred from the data that: i) residents' satisfaction of pedestrian environment will influence the duration of their outdoor leisure walking. The more they are satisfied with environment, the more they will walk; ii) satisfaction of traffic safety and satisfaction of quality have a lower correlation with walking duration than other satisfaction indexes. It shows that residents' recognitions to the traffic safety and quality of current pedestrian environment are lower than other indexes. Such situation reveals the common problems existing in neighborhoods from another aspect.

Table 1. Correlation test between 'satisfaction of walking environment' and 'leisure walking activities'

Pearson Correlation		Satisfaction						
		Whole Environment	Accessibility of Public Transit	Accessibility of Commercial Services	Convenience of Road Network	Traffic Safety	Security	Quality
Walking Frequency	Avg.							
	Historical Neighborhood							
	Workers' Village							
	Old Neighborhood							
	New Neighborhood		.091*			.117**		
	International Neighborhood							
Walking Duration	Avg.	.079**	.062**	.060**	.058**	.046*		.045*
	Historical Neighborhood							
	Workers' Village	.082*		.078*				
	Old Neighborhood	.116**				.080*	.075*	
	New Neighborhood	.117**	.141**	.078*	.102**	.091*		
	International Neighborhood				.102*			

* $P < 0.05$, ** $P < 0.01$

ii) Variables of Spatial Morphology of Neighborhoods

Table 2 shows the effect that spatial morphology of neighborhoods on residents' leisure walking frequency is greater than it on residents' leisure walking duration. All the factors of urban morphology are highly related to walking frequency except public transit service.

Table 2. Correlation test between ‘space morphology variables of neighborhood’ and ‘leisure walking activities’

Spatial Morphology Variables		Walking Frequency	Walking Duration
Neighborhood's Attributes	Land Area		
	Population Density	.131**	
Spatial Texture	Average Block Length		
	Density of Intersections		
	Section-Node-Ratio	.046*	
	Density of Neighborhood's Entrances		
Land Use	Density of Centralized Commercials		
	Density of Commercial Interfaces	.050*	
	Density of Commercial Interfaces ≥ 15 Stores (Per 100m)	.083**	
	Proportion of Commercial Interfaces ≥ 15 Stores (Per 100m)	.119**	
	Proportion of Commercial Interfaces < 5 Stores (Per 100m)	-.131**	
	Density of Educational Facilities		
	Density of Medical Facilities		
	Density of Cultural Facilities		
	Density of Office Buildings		
	Density of Community Service Facilities		
Public Transit Service	Density of Public Green Areas	-.056**	-.054**
	Complex Degree of Functions (Entropy)	.085**	
	Density of Bus Stops		
Walking Facility	Density of Bus Routes		
	Density of Subway Stations

	Interfacial Density of Penetrable (Green) Interfaces	-.066**	
	Interfacial Density of Closed Interfaces		

* $P < 0.05$; ** $P < 0.01$

It can be inferred that: i) objective spatial forms of neighborhoods are more likely to affect residents' choice of leisure walking. But it is very difficult to influence the length of time that residents spent on their daily leisure walking. Walking duration may be more influenced by individual subjective perception of the environmental quality; 2) the atmosphere of commercial vitality in the street is the most important factor which can attract leisure walking. The longer and denser interfaces of the stores are, the more abundant commercial vitality and social activities of the neighborhoods will be. And the attraction to the residents to make daily leisure

activities will also be stronger. Penetrable (green) interface and closed interface which contain no commercial element cannot attract residents' leisure activities; 3) high population density mode and mixed land use are useful to make the spaces of neighborhoods compact and diversified. Thus, it will promote different social groups using the spaces and having activities. Mixed land use also means diversity of urban space. Hence, a neighborhood is no longer a simple combination of many buildings. It will show the complexity of spaces and activities. And that would attract residents' leisure activities; 4) wide space with pavement of hard material can attract leisure walking more than public green. Those sidewalks above 10 meters width can accommodate street fitness, dance and other community activities. And they also can provide outdoor seating of café and other leisure facilities. Such things will benefit for residents to make their leisure walking. However, the higher the density of public green in neighborhood, the lower frequency and duration of leisure walking residents would have. Probably, it is because the designs of many green parks paid attention to the visual image and green coverage rate only, and didn't provide sufficient places and facilities for walking activities. So, there is still a gap between the reality and the residents' demands of the leisure; 5) penetrability of sidewalk network in neighborhood can facilitate walking leisure activities. Section-node -ratio of roads reflects the penetrability of road network in neighborhood. The density of residential areas' entrances and the density of parks' entrances reflect the penetrability between inside and outside of a closed area (Park). The higher the density is, the stronger the penetrability of a neighborhood's space is. The sidewalk network in a neighborhood with strong penetrability can provide residents more choices of routes, increase diversity and complexity when experiencing the walking environment, and provide more chances for neighbors to encounter, stay and exchange as well.

Regression analysis of model

The correlation analysis merely explains the relationship between two variables. Regression equation is needed to carry on further analysis. It is helpful for quantitative study on the effect what multiple independent variables (X) influence on dependent variable (Y). It can be found by the previous correlation analyses that leisure walking frequency is influenced more by spatial morphology factors of neighborhoods. Therefore, in the multiple logistic regression analysis, walking frequency is taken as the dependent variable (Y) to be calculated.

Basic Model I

The multiple logistic regression analysis was made by taking residents' leisure walking frequency as dependent variable and taking residents' personal attributes variables as independent variable. Took the frequency = 0 time per week as a reference target, and got the Basic Model I. The Pseudo R Square (Cox and Snell) = 0.394, that means the model is valid.

Basic Model is:

$$\text{LN}(P_i/P_0) = \beta_i + \beta_{ig1}X_{g2} + \beta_{ig2}X_{g3} + \beta_{ig3}X_{g4} + \beta_{ig4}X_{g5} + \beta_{ig5}X_{g6}$$

(X_{g2} —Age; X_{g3} —Career; X_{g4} —Education; X_{g5} —Number of family members; X_{g6} —Monthly income; “i” means walking frequency per week; In 6 sub-models, “i” respectively equals to 1,2,3,4,5,6)

In order to study the level that different personal attributes influence on leisure walking, the changes of numerical value of Pseudo R Square should be observed by removing the variables which were retained by regression from Basic Model I one by one. The Pseudo R Square reflects the fitting degree of the whole model. So, if the change of numerical value of Pseudo R Square is big when removing a variable, it means this variable is significant to model fitting. The calculation results are shown in Table 3.

It can be inferred that: i) age is the key variable of personal attributes affecting residents' leisure walking frequency. And the significance of age presents a raising effect with increasing frequency; ii) the higher the monthly income of one's family, the less the possibility of all frequencies he/she choose to have leisure walking. The possibility is that people with high salary have more ways of leisure, and they don't need to always choose leisure walking activities; 3) those who are retired or don't work are more likely to choose the high frequency of leisure walking than students or office workers. The mainly reason is that they have more free time.

Table 3. Selection of the Personal Attribute Variables

Personal Attribute	Contribution of Pseudo R Square	Significance Level of Likelihood Ratio Test	B Value (When the Significance Level of Sig<0.1)					
			Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Age	.110	.000		.567**	.877**	1.210**	1.803**	2.641**
Number of Family Members	.016	.033	.238*	.287**				
Education	.007	.035	.302**	.344**	.367**			
Monthly Income	.004	.000	-.651**	-.305**	-.266**	-.292**	-.368**	-.311**
Career	.003	.016					.373**	.443**

* 0.05<Sig<0.1; ** Sig<0.05

Model II

Leisure walking activities is an act of strong subjective consciousness. Residents' attitudes to walking and perceptions of environments may have significant influence on choices for leisure walking. Hence, added these variables to Basic Model I and selected the new added variables by logistic regression automatically. Finally got the Basic Model II, and its value of Pseudo R Square (Cox and Snell increased from 0.394 to 0.421). Fitting effect of model is better.

It can be inferred from the contribution of Pseudo R Square (Table 4) that "Close to nature and have relaxation" is the key variable of subjective perception affecting residents' leisure walking frequency. In a big city where the pace of life is fast, when residents realize that walking can promote physical and mental health, they would tend to make more leisure walking activities. The pedestrian environment that is clean, comfortable, spacious and safe will promote residents' choice of leisure walking activities of high frequency. Then walking may become a daily habit.

Model III

The spatial morphology variables, which were selected by correlation analysis according to the rule of P value < 0.05 with leisure walking frequency, were put into Basic Model II respectively. Influential degree of a morphology variable was ascertained by observing the change of Pseudo R Square after adding it into Basic Model II. And its effect to residents with different frequency of leisure walking was analyzed by its model parameter value (B) and significant value (Sig.) in 6 sub-models. The calculation results are shown in Table 5. Key

variables of spatial morphology are: proportion of sidewalks ≥ 10 meters width, complex degree of function (entropy), density of parks' entrances, proportion of commercial interfaces < 5 stores (per 100m), section-node ratio, proportion of commercial interfaces ≥ 15 stores (per 100m).

Table 4. Selection of Walking Attitude Variables and Perception Variables of Pedestrian Environment

Attitude and Perception Variables	Contribution of Pseudo R Square	Significance Level of Likelihood Ratio Test	B Value (When the Significance Level of Sig < 0.1)					
			Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Close to Nature and Have Relaxation	.012	.000	.671**	.721**	.921**	.839**	.834**	1.382**
Dirty and Disorderly Environment Making Walking Uncomfortable	.006	.002			.392*	.829**	.638**	.479*
Spacious Walking Space	.004	.048			.693**	.515	.860**	.897**
Satisfaction of Security	.004	.069				.500**	.502**	.575**
Be Beneficial to Physical Health	.003	.271				.531*	.426	.750**

* $0.05 < \text{Sig} < 0.1$; ** $\text{Sig} < 0.05$

It can be inferred that: i) under the influence both of personal attributes and perception variable, “proportion of sidewalk > 10 meters width” is the key spatial morphology that influence residents' leisure walking frequency. Spacious walking places (such as small squares in corners of streets, small gardens and the spaces formed by the backward parts of buildings) can accommodate the walking activities that keep pedestrians staying. Provide spacious places for residents' near there to having their outdoor leisure activities, such as chatting, dancing, doing exercise, sitting at leisure, having tea, playing chess and playing cards. Gradually, such places become the conventional sites with function of social contact in community. And that would attract people promenading there to meet each other; 2) complex degree of function in land use and commercial interfaces with high density of small stores are useful to induce residents to choose walking leisure activities in medium or high frequency. It undoubtedly verified the results of previous correlation analyses. Mixed land use can not only promote efficient and intensive use of land in a city and be helpful to realize the accessibility of walking activities in a short distance, but also create diversity and continuity of the interfaces along the streets. Dynamic and interesting interfaces of streets make pedestrian feel safe and pleasure both in visual and psychological experience. And then leisure walking activities would be promoted; 3) the penetrability of sidewalk networks in neighborhoods will also have an impact on the residents' leisure walking activities. Sidewalk networks with good connectivity increase the number of routes, offer more choices of walking routes for residents, and rich the experiences of leisure walking activities in sites. Parks are important leisure sites in neighborhood. Increasing entrances of parks can effectively improve their accessibility. It would be convenient for

residents to use and have a strong influence on attracting leisure activities with high frequency especially.

Table 5. Selection of Spatial Morphology Variables in Neighborhoods

Spatial Morphology Variables	Types	Contribution of Pseudo R Square	Significance Level of Likelihood Ratio Test	B Value (When the Significance Level of Sig < 0.1)					
				Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Proportion of Sidewalk > 10 Meters Width (%)	Walking Facility	.006	.003				.321**	.312**	.258*
Complex Degree of Functions (Entropy)	Land Use	.005	.007	.312**	.353**	.271**	.400**	.393**	.364**
Density of Parks' Entrances (per km ²)	Walking Facility	.005	.015	.357**	.447**	.387**		.420**	.407**
Proportion of Commercial Interfaces < 5 Stores (Per 100m) (%)	Land Use	.005	.019	-.303**	-.232**	-.247**	-.299**	-.397**	-.433**
Section-Node -Ratio	Spatial Texture	.004	.040			.286**	.337**	.362**	.320**
Proportion of Commercial Interfaces ≥ 15 Stores (Per 100m) (%)	Land Use	.001	.773						.237*

* 0.05 < Sig < 0.1; ** Sig < 0.05

Conclusion

Objective spatial morphology variables of neighborhoods mainly influence residents' leisure walking frequency, but have little effect on the duration. Subjective satisfactions of pedestrian environments, which are subjective evaluation formed by individual cognition to the spatial morphology, have little effect on residents' leisure walking frequency, but evidently on the duration. Frequency indicates the times of leisure walking trips, while duration indicates the quality of leisure walking activities. Therefore, improving objective environment can encourage residents to make more choices for leisure walking, while increasing the degree of subjective satisfactions of walking environments can extend the duration of walking activity.

In order to promote more residents' leisure walking, designs of spatial morphology of neighborhoods should focus on the following aspects: enhancing penetrability of sidewalk networks; improving mixed functions of land use; increasing the density of commercial interfaces along the streets; offering spacious sites paved with hard materials; optimizing designs of public greens; creating a safe and clean atmosphere of the community. In addition, the personal attributes and the subjective demands of residents will also affect whether they choose leisure walking or not. For example, the thoughts of closing to nature, having relaxation and being beneficial to physical health will promote the occurrences of leisure walking activities. That means the construction of neighborhoods' morphology should pay attention to the layout and design of natural ecology and fitness facilities of pedestrian environments.

Comparative studies of urban form

There is a long tradition of comparative studies of urban form. In the early years of development of urban morphology as a field of knowledge, German-speaking researchers in particular were active in making both inter- and intra-urban comparisons of the physical forms of cities. Indeed comparisons over time became inherent in the concept of the morphological period, which has figured explicitly or implicitly in much morphogenetic research. In a twenty-first century environment in which the scope for international research has become so much greater, a wider compass of comparisons of many types has become increasingly realistic. Perhaps most obvious is the opportunity for cross-cultural comparisons. However, the success of both these and more local comparative studies will relate importantly to progress in research, including comparative research, relating to concepts, theories, methods and different disciplinary perspectives. In these respects the scope for shedding fresh light on urban form by comparative studies is great indeed. This is not to argue that research on individual cities and parts of cities should become of lesser importance. The key point is to ensure that research at whatever geographical scale is placed within a comparative framework. As perceptive researchers were aware long ago, research is not just about particular places. It is about the light that work on a particular place can shed on places more generally, and vice versa. To achieve this, other needs must be addressed: not least it is important to work more actively towards common definitions of the terms being employed. This is a major challenge in a field characterized by a wide range of perspectives, including those emanating from different disciplines and language areas. However, we should take strength from the fact that it was particularly to meet this challenge that ISUF was formed!

Urban Transformation in Meeting Places: The Cases of Bursa & Yazd'

Sima Vaez Eslami, Ayse Sema Kubat

Department of Urban & Regional Planning, Istanbul Technical University.

E-mail: eslami@itu.edu.tr-kubat@itu.edu.tr.

Abstract. *In the 19th century, due to modernization programs, historical cities faced powerful socio-spatial transformations. While the traditional urban structure of historical cities, which was the outcome of an incremental growth, was created over centuries, the new urban pattern system was imposed on historical urban fabrics and led to some serious damages on the body of historic urban fabrics all over the world. Islamic cities underwent the same type of modifications, as well. For example, in the city of Yazd (an Islamic Iranian city), the grid urban pattern was imposed on the organic structure which not only affected the physical form of this historic city, but also caused many social and economic changes within the traditional life of people.*

This research uses space syntax as a tool for investigating what modernization meant for Islamic cities; how the modern changes affected the traditional urban pattern especially the structure of meeting places and to find why it was necessary to preserve the old structure of historical cores in Islamic cities.

Key Words: *Islamic Cities, Urban Transformation, Space Syntax, Yazd, Bursa*

Introduction

From the past to the present, the cities in the world have faced different changes and transformations. Due to urban modernization programs, many historical fabrics of traditional cities were seriously demolished to create new open spaces for new roads and constructions. In the Middle East, the industrial and urban modernization of the Islamic cities date back to the 19th century which changed the morphological, social, and physical characteristics of The Middle Eastern Islamic cities after a short rapid growth period of urban modernization in Europe. This paper attempts to investigate what modernization meant for Islamic cities by using space syntax as a tool. The main focus of this study is to present the impact of urban modernization on the structure of meeting places in Islamic cities through an analytical investigation of the urban structure before urban modernization and at the present time. Although there are other studies, such as “Urban conservation and spatial transformations preserving the fragments or maintaining the spatial spirit” by Kayvan Karimi and “The morphological characteristics of Anatolian fortified towns” by Ayse Sema Kubat, that investigated the effect of urban change on the historic core through using space syntax tool, this research takes a unique approach to find the effect of urban modernization on the structure of meeting places in two Islamic cities being Bursa and Yazd in two different countries, Turkey and Iran, respectively.

Urban Form in Islamic Countries

A traditional (pre-industrial) Islamic city according to orientalist generally includes the following characteristics: a medieval citadel or fort, a nearby central market (bazaar) and one or more public baths (hammam) clustered around a Friday mosque, a religious school (madrasa) and caravanserai, a narrow irregular street pattern, ethnic quarters, houses with courtyard, medieval walls and gates, and a complete lack of open civic space other than the Friday mosque courtyard (Abu-Lughod 1993; Bianca 2000). In Islamic urban model "Islam" was considered an

"urban" religion, to make people live together in communities. Streets were not designed in purpose as in American and European cities, after the mid-nineteenth century, but were composed of leftover space after houses were built.

Belkacem (1982) emphasizes the importance of the enclosure of space in Islamic civilization as a symbol of the relationship between body and soul. In Islamic urban pattern public space was also enclosed if possible. These public spaces could include covered markets, caravanserais, madrasa, and mosque courtyards (Abu-Lughod 1993).

Physical Dimensions of City of Bursa, from Past to Present

The city of Bursa is located in the Northern western region of Anatolia in Turkey. It is believed that Bursa was found by Prusias in about 150 B.C. (I.Orbay, 1983). In 1326 Bursa was taken from Byzantines, and became part of the Ottoman Empire, and Ottomans started to Islamize the environment of the city for example, Byzantine church was changed to a mosque. The first core of the city of Bursa was surrounded by a fortress and Bursa was a fortified town (figure 1), after a period of strengthening, the city of Bursa started to extend out of the fortified core. The Orhan Gazi Mosque, a public bath (Hemmam), and a commercial complex (bazaar and han), were built to the east of the fortress (T.J. Heng, 1985). The development of the city continued on an area on the outside of the fortress.

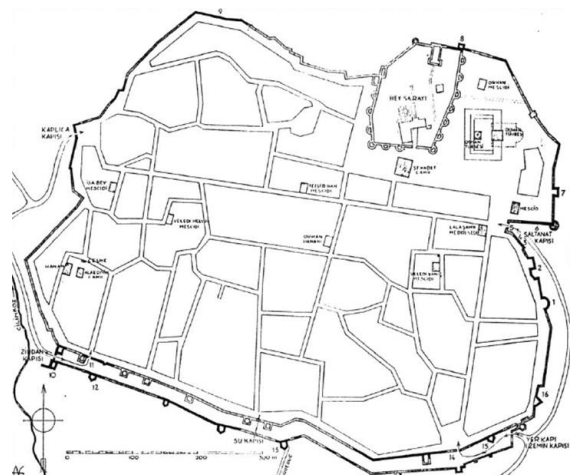

Figure 1. Plan of Hisar (Heng 1985).

New commercial buildings were built, such as bedesten, arasta bridge, bazaars, open market places and stores. In the Islamic city of Bursa the commercial square of the city was its focal point and like other Islamic cities the residential quarters (Mahalla) were located around it. These residential quarters were connected to the heart of the city (Commercial Square) by urban access roads (Figure 2).

In the 19th century, the industrial revolution in Europe had a critical impact on Bursa, and industrialization and westernization program was started by the Ottoman Empire to adjust city of Bursa to the West. After deterioration of the Ottoman Empire, new urban modernization projects were started. During these new urban modernization constructions, historic core of the city (commercial square) were surrounded by new wider streets such as: Atatürk Street on the South, İnönü Street on the East, and Cumhuriyet Street on the North, Figure 3 shows the roads at the end of the 19th century and at the beginning of the 20th. So, after new urban constructions the commercial area which was occupying a large area of the city in the 16th century was limited with mentioned streets. New wide roads were created to provide suitable traffic, but had caused demolition of many historical monuments.

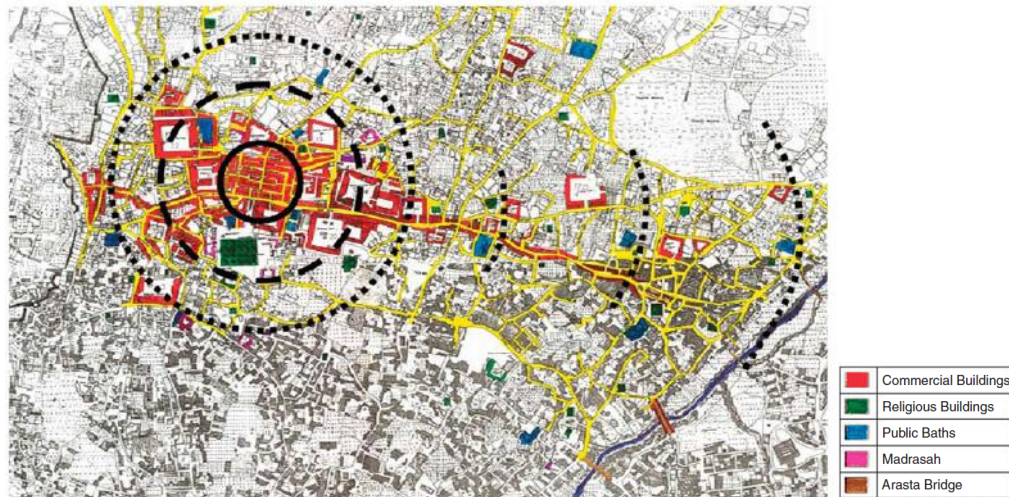

Figure 2. The historical evolution of commercial buildings in the Khans region at the end of the 16th century (Baghanci, 2010).

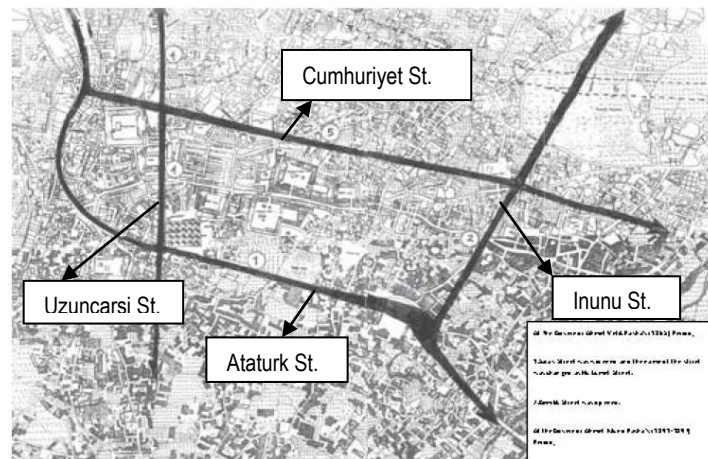

Figure 3. The roads at the end of the 19th century and at the beginning of the 20th century (Baghanci, 2010).

Physical Dimensions of the City of Yazd, from Past to Present

The city of Yazd is located in the center of Iran surrounded by two major deserts, Dasht-e-Kavir and Kavir-e-Loot. The walled city of Yazd developed in different stages from pre- Islamic era till the 14th century. In pre- Islamic era the urban pattern of the city of Yazd was the same as other Persian cities at that time, however, after the Islamization of Iran, the urban pattern of the city changed to organic urban form with the main elements of an Islamic city such as: bazaar, Friday mosque, public bath, religious school and several residential neighborhoods. In the beginning of the 15th century an urban complex consisted of a bazaar, a Friday mosque and a water reservoir was built around the city square which was located at the extreme South-East of the city. This new addition was called Amirchaqmaq Square (Afshar, 1995). The old city center, which was around the old Friday mosque (Masjid-I-Jame) was gradually merged with this square. The bazaar of the city also extended from the old Friday mosque to Amirchaqmaq square as a good link between the old city center and the new one. In 1790; in the south-West of the walled city another square surrounded by commercial and public activities was built and called "Shahtahmasb" square. Shahtahmasb square was well connected to the Amirchaqmaq

square by an axial road full of commercial functions. In the 19th century, another new complex consisting of religious school, mosque, public bath, water reservoirs was built in the middle of a commercial route between Amirchaqmaq and Shahtahmasb squares and was called "Khan" square-khan square later- became the most important city center for commercial activities (Figure 4).

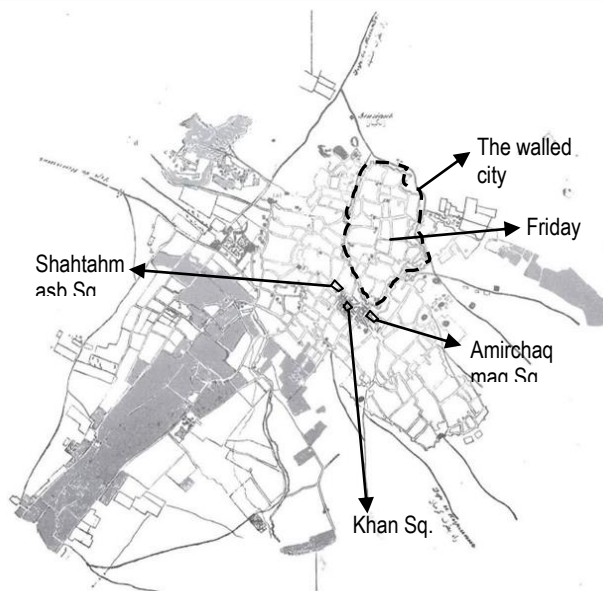

Figure 4. The city of Yazd in 1859 (Afshar, 1995).

The first and the most significant urban modernization activity was done by the order and decision of Reza Shah (1925-1941) to drive a major network of long, wide and straight streets as could be seen in most other Iranian cities (Wilber, 1981). Due to urban modernization constructions the heart of the old city of Yazd was demolished. The construction of Ghiam and Imam (Shah and Pahlavi) streets was the first sign of urban modernization and significant change in the old city of Yazd. The bazaar was divided into two parts by Ghiam Street (Figure 5).

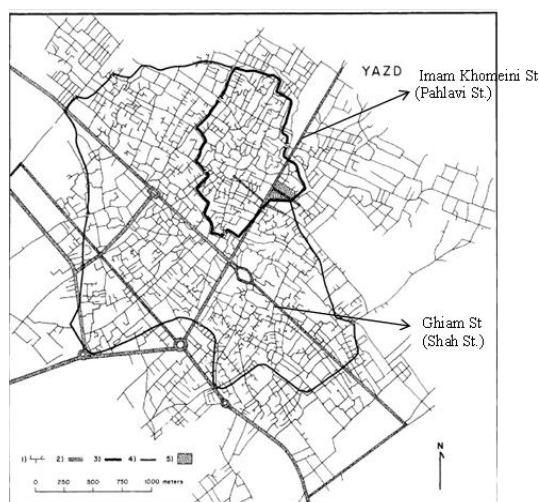

Figure 5. The first sign of urban modernization by construction of Pahlavi and Shah Streets (Afshar, 1995).

Methodology

In order to do a morphological analysis of the selected cities, a mathematical model, called space syntax technique, was applied. Space syntax was developed by Hillier and Hanson at the Department of Architectural Studies, University College of London (Hanson 1989; Hillier 1989, Hillier & Hanson 1984; Hillier et al 1983; 1992; 1993). "Space syntax is also one of the few theories which allow us to understand how culture and society are embedded in the specific relational patterns constituting architecture and urban design. The aim of the technique is to describe different aspects of relationships between the morphological structure of human-made environments and social structures and events. It is possible to give quantitative descriptions of built spaces. This methodology contributes greatly to understanding of the physical structure of the cases in this study" (Kubat, 1997). As this paper is not submitted to any Space syntax symposium, a number of analytical and technical ideas used in the paper are defined here in order to help readers.

Axial map: "The axial map is the basis of settlement layout analysis. This represents the distance up to which an observer can have an uninterrupted impression of visibility and permeability as he move about the town and look in various directions. The map is derived by drawing the fewest and the longest lines of uninterrupted permeability necessary to cover the public open space of an area. The size of a settlement system is measured in terms of the number of lines." (D. Dhima, 2006).

Connectivity: "Measure the number of the immediate neighbors that are directly connected to the spaces. In axial map connectivity of an axial line is measured by the number of lines that are directly intersecting that line" (D. Dhima, 2006).

Integration: "Integration measures how many turns one has to make from a street segment to reach all other street segments in the network, using shortest paths. If the amount of turns required for reaching all segments in the graph is analyzed, then the analysis is said to measure integration at radius 'n'. The first intersecting segment requires only one turn, the second two turns and so on. The street segments that require the least amount of turns to reach all other streets are called 'most integrate' and are usually represented by hotter colors, such as red or yellow. Integration can also be analyzed in local scale, instead of the scale of the whole network. In case of radius 4, for instance, only four turns are counted departing from each street segment. Theoretically, the integration measure shows the cognitive complexity of reaching a street, and is often argued to 'predict' the pedestrian use of a street"(D. Dhima, 2006).

Intelligibility: Hillier (1988, 1996) defined intelligibility as "the degree to which what can be seen and experienced locally in the system allows the large-scale system to be learnt without conscious effort" (Hillier, 1996, p. 215). In practice, the intelligibility value is calculated by the degree of linear correlation between connectivity and the global integration value (Hillier and Hanson, 1984).

Syntactic configurational measurements

To start the syntactic analysis of the spatial configuration, it is imperative to draw axial maps first. Then, this axial map (in DXF format) should be imported into a Depth Map software to produce a visibility graph which shows the value of Integration by ranging from red (or black) for the most integrated lines to blue (or light gray) for the most segregated ones. By the use of this map, the researchers were able to find the value of global integration and connectivity and the correlation between these values results in value of intelligibility.

Data collection and analysis

In this part, Syntactic Configurational Measurements of Bursa and Yazd will be presented, respectively. The results obtained from the gathered data will also be analyzed.

Syntactic Configurational Measurements of the City of Bursa

To start the space syntax analysis on the city core of Bursa before and after urban modernization constructions, the axial line of the city core in both conditions were drawn and imported to Depth map software in the context of connectivity (See Figure 6).

Figure 6 shows the connectivity map of the old city of Bursa in 1860 (top) and in the present time (bottom), red color lines indicating the highest value of connectivity and the blue featuring the least one. As it is clear from the connectivity map of Bursa in 1860, the most connected lines on the map are the route of bazaar which is called "Uzun Carsi" street at the present time. The axial line of this street is shown by o-Max on the map and its connectivity value is 9. It is obvious that the points with high value of connectivity are located in the center of the area and lines with low value of connectivity are located on the borders of the study area. According to the connectivity map of Bursa in present time, the maximum connectivity value is 24 at the point marked by n-Max, which is located on "Cumhuriyet" Street, one of the most important streets that surrounds the historic core.

Table 1 shows the key connectivity values of the city of Bursa in 1860 and the present time. According to this table, due to new road constructions, the mean connectivity value in the city of Bursa increased from 2.98 to 3.45 and as it was mentioned earlier, in 1860 "Uzun Carsi" street had the most connectivity value (Value of 9); however, in the present time "Cumhuriyet" Street has the most value of mean connectivity (value of 24).

Figure 6. The connectivity map of the city of Bursa in 1860 (top) and in present time (bottom).

Table 1: The Key Connectivity Values of the City Of Bursa in 1860 and Present Time

Connectivity	Value	
	Old Bursa	New Bursa
Average	2.98	3.45
Minimum	1	1
Maximum	9	24
Number of counts	461	1731

Figure 7 shows the global integration map of the city of Bursa in 1860 and in the present time. Red color lines indicate the highest value of integration (R_n) and the blue lines refer to the least value. Accordingly, in the old city of Bursa bazaar route has the most value of integration (0.95) marked as i-Max and the lowest integrated part is shown by i-Min which has 0.35 value of integration located far from the city core on the border.

In reference to global integration map of Bursa in the present time, the highest integration value marked as d-Max with a value of 1.13 is located on the "Ulu Cami" street which passes through the historic core of the city. The lowest integrated part is shown by d-Min which has 0.29 integration value and is located far from the city core on the border. So, even after urban modernization process, the most integrated part of the city is the center and around the historic core of the city. It is noteworthy that the integrated core of the old city of Bursa has been preserved after urban modernization constructions.

Figure 7. Comparison between axial line maps (integration R_n) of historical city of Bursa in 1860 (top) and at present time (bottom).

In the next step the value of intelligibility (the value of correlation between mean global Integration and mean connectivity value) for city of Bursa before and after urban modernization constructions; is calculated. According to this calculation the value of intelligibility has been decreased from 0.29 to 0.10 after urban modernization and urban growth. This reduction explains that the sense of legibility and way finding dropped after urban modernization in city core of Bursa.

In order to find the impact of urban modernization and urban growth on the structure of meeting places in the historic core of the city, the average of integration values of each type of meeting places in the city of Bursa in both conditions were measured (by measuring the average of global integration of all the entrances of each building). Table 2 shows that the hierarchy orders of mean value of global integration of historic meeting places in the city of Bursa is not disrupted after urban modernization transformation.

Table 2. Comparison between the Hierarchy of Integration Value of Meeting Places in the City of Bursa in 1860 and in Present Time.

Meeting space	Value of Integration Rn	
	Old Bursa	New Bursa
Bazaar	0.87	0.99
Mosque	0.85	0.95
Public bath	0.77	0.94
Religious school	0.76	0.92

Syntactic Configurational Measurements of the City of Yazd

Having analyzed Syntactic Configurational Measurements of the City of Bursa, the researchers repeated the same process with the second city of the study, Yazd. To start the space syntax analysis on the city core of Yazd before and after urban modernization constructions, the axial line of the city core in the two conditions were drawn and imported to Depth map software in the context of connectivity. Figure 8 shows the connectivity map of the old city of Yazd in 1928 (top) and in the present time (bottom), red color lines indicating the highest value of connectivity and the blue showing the least value. As it is clear from the connectivity map of Yazd in 1928, the most connected lines on the map are located on the rout of bazaar near the "Khan square."

The axial line of this street is shown by h-Max on the map and its connectivity value is 10. According to the connectivity map of Yazd in present time, the maximum connectivity value is 29 at the point marked by i-Max, located on "Imam Khomeini" Street which is one of the first streets constructed in 1928.

Table 3 shows the key connectivity values of the city of Yazd in 1928 and in present time. According to this Table, the mean connectivity value in the city of Yazd increased from 2.62 to 2.69 by urban modernization constructions and the most connectivity value (29) belongs to "Imam khomeini" street (at present time).

Table 3. Key connectivity values of the city of Yazd in 1928 and at present.

Connectivity	Value	
	Old Yazd	New Yazd
Average	2.62	2.69
Minimum	1	1
Maximum	10	29
Number of counts	943	2498

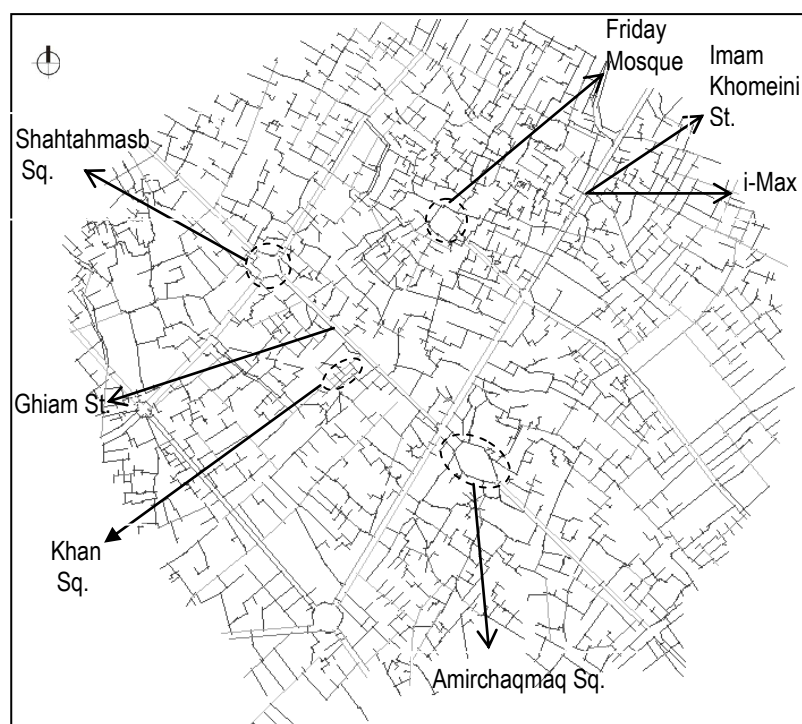

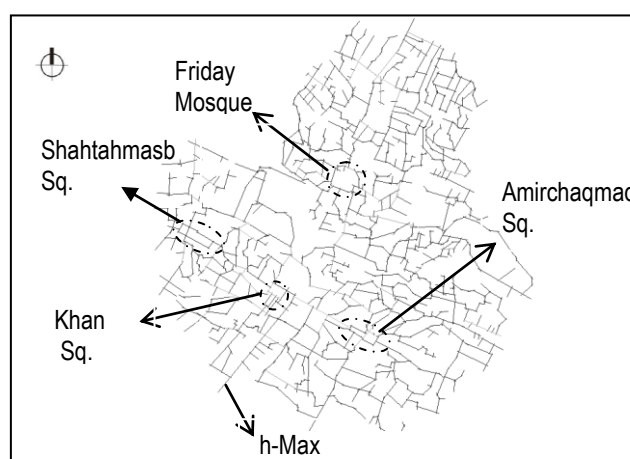

**Figure 8. The connectivity map of the city of Yazd in 1928 (top) and present time (bottom).**

Figure 9 shows the global integration map of the city of Yazd in 1928 and in the present time, red color lines indicate the highest value of integration (R_n) and the blue ones show the least.

According to Figure 9 in the old city of Yazd, the most integrated part is seen to be in the central part of the urban system indicated by red and less integrated parts are located around the borders which are far and poorly connected to the center. The highest integration value marked as a-Max with a value of 0.532 is located on the route of bazaar which is in a very central point of the system. The route of bazaar makes a good connection between two cores of the city (Friday Mosque and Amirchaqmaq squares). The lowest integrated part is shown by a-Min which is located far from the city core and on the border.

Regarding global integration map of the city of Yazd in present time, the highest integration value marked as d-Max with a value of 0.77 is located on "Ghiyam" street which passes through the historic core of the city. The lowest integrated part is shown by b-Min which has 0.28 value of integration. According to Figure 9, it is not on the border and it is near the center of the city.

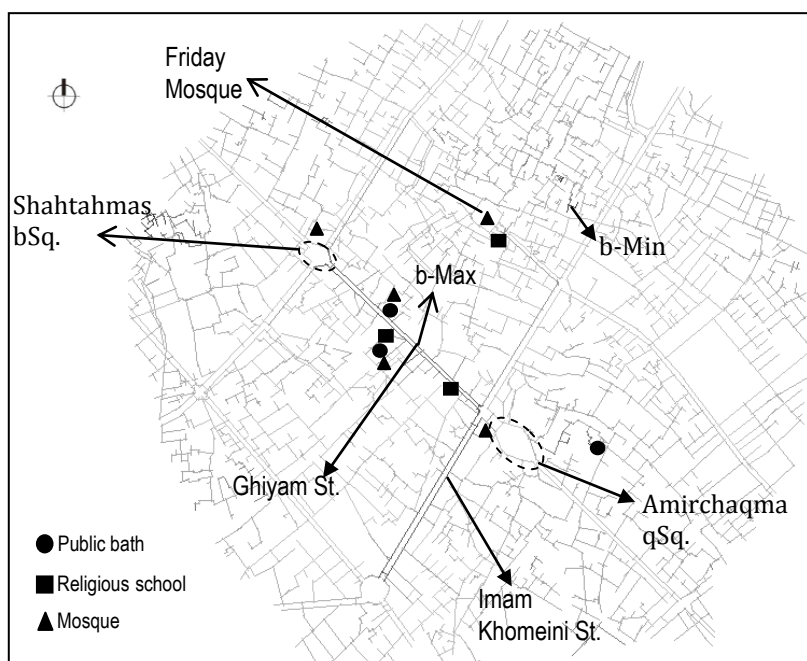

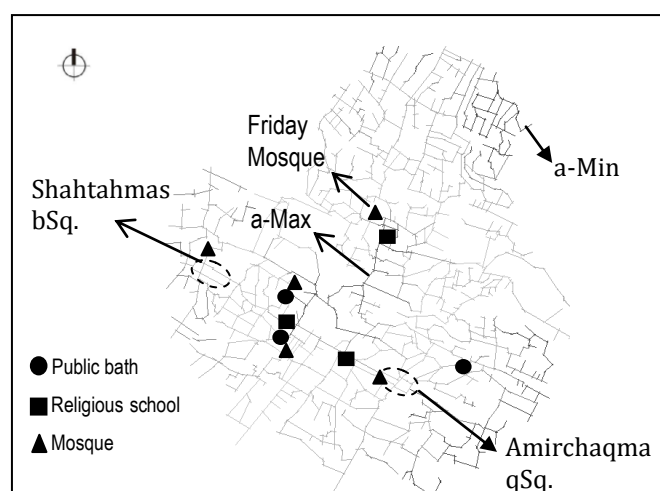

Figure 9. Comparison between axial line maps (integration R_n) of historical city of Yazd in 1928 (top) and at present time (bottom).

In the next step value of intelligibility for city of Yazd before and after urban modernization constructions is calculated. According to this calculation the value of intelligibility has been decreased from 0.09 to 0.07 after urban modernization and urban growth. This reduction explains that the sense of legibility and way finding dropped after urban modernization in city core of Bursa.

In order to find the effect of urban modernization and urban growth on the structure of meeting places in the historic core of the city, the average of integration values of each type of meeting places in the city of Yazd in both conditions is calculated (See Table 4). According to the table 4, in the old city of Yazd, bazaar has the highest global integration value and public bath has the lowest one; while at present time Religious School (Madrassa) is the most integrated urban element and Mosque has the lowest global integration value among other historical meeting places meaning that urban structure of meeting places in city of Yazd has been disturbed by urban modernization constructions.

Table 4. Comparison between the Hierarchy of Integration Value of Meeting Places in the City of Yazd in 1928 and in Present Time

Meeting space	Value of Integration Rn	
	Old Yazd	New Yazd
Bazaar	0.47	0.66
Religious school	0.45	0.68
Mosque	0.43	0.54
Public bath	0.39	0.56

Comparison and conclusion

In the present study, the urban pattern of two different Islamic cities namely Bursa and Yazd in two different countries, Turkey and Iran, has been examined comparatively from the point of view of identity, including their mathematical analysis. The main objective of this comparative study is to find the impact of urban modernization transformation on old structure of historic cores of these traditional Islamic cities. Such a study is helpful in contemporary urban studies, especially for the renovation of the historical and cultural regions of the cities that are changed and damaged by the effects of rapid urban modernization and urban growth programs.

Both of these cities had an organic urban pattern before urban modernization transformation; however, in the city of Yazd grid urban pattern was imposed on the old organic pattern of the city, thus the urban structure of the city changed dramatically. In addition, some parts of the bazaar of the city were demolished due to such urban modernization system. But in the city of Bursa, a new ring road was constructed around the historic core of the city without any dramatic changes or demolitions in historic areas.

According to the analyzed maps (Integration radius n) of the old cities of Yazd and Bursa before urban modernization transformation, in both cases the maps of global integration (radius n) create a clear structure based on a powerful and compact integration core in the centre of the organic pattern of the city. The most integrated part of the city is the city core that the mostly-used places such as bazaar, mosque, madrasa and public bath are located in this part of the city. The map of global integration (Rn) for the core of Iranian city demonstrates a total destruction of the old global configuration. The modern streets (Ghiyam and Imam Streets) are the most integrated lines of the systems. Since these streets have not been constructed in any accordance

to the older organic street patterns, the new integration core totally ignores the older centre of integration. In fact, the historic integrated core of the old city is lost after urban modernization transformation and changed to integrated streets. On the other hand, some lines which used to be segregated become integrated and vice versa. The story in the historic core of Turkish city is completely different. First of all, the historic core in the context of the whole city has not been lost through urban modernization. The pattern of global integration in core of modern city of Bursa follows the pattern of integration in the traditional city of Bursa. In other words, the most integrated streets are around the historic core of the city now and then with a seemingly more expanded new integration core. Another remarkable notion obtained from the analysis of the city of Bursa is that the segregated lines still are located in the borders and far from the city core.

Table 5 is a Comparative analysis of the cities of Bursa and Yazd in before and after urban modernization transformation. According to the table the value of global integration of the city of Bursa is more than that of the city of Yazd's in both the old and new conditions. On the other hand, the value of global integration of both of these cities has been increased after urban modernization process. Due to the construction of wide streets and highways as well as the demolition of traditional narrow streets and cul-de sacs, the urban structure of both these Islamic cities has been developed after urban modernization constructions. Value of mean connectivity in the city of Bursa is more than that of the city of Yazd's in any conditions. On the other hand, the Increase in value of mean connectivity in the city of Bursa is remarkably more than the city of Yazd meaning that new road constructions in the city of Bursa have been more than in the city of Yazd.

According to the table 5 the intelligibility of city core in city of Yazd is poor in any condition and its value decreased after urban modernization. The intelligibility of city core in city of Bursa is also reduced after urban modernization process; however the correlation between global integration and connectivity in city of Bursa is higher than intelligibility value in city of Yazd in any condition.

The major objective of this study is to examine the impact of urban modernization on urban structure of meeting places in Islamic cities of Yazd and Bursa. It is worth discussing the ways the constitution of meeting places in the city changes when its spatial structure transforms. As discussed in the previous sections, the pattern of global integration in the historic core of the city of Bursa has not changed dramatically, thus kept the original urban structure of meeting places in the core of the city. In other words, the hierarchy orders of the mean value of global integration of meeting places in the city core of traditional city of Bursa before urban modernization is similar to the modern city now. It means the most integrated meeting places before urban modernization process were "bazaar" and "mosque" and the most segregated elements were "public bath" and "religious school". This order is preserved after urban modernization process (See Table 5).

On the other hand, the global position of meeting places in the city core of the old city of Yazd has been disturbed dramatically by urban modernization process. In other words, the most integrated meeting places in the old city of Yazd were "bazaar" and "mosque" and the less integrated public places were "religious school" and "public bath". However, after urban modernization process the global position of meeting places changed dramatically. It means the most integrated meeting places after urban modernization process become "religious school" and "bazaar" and the less integrated buildings are "public bath" and "mosque". According to the above findings and also other results in the previous sections, it is apparent that in the city of Yazd, a larger entity, i.e. the configuration organization has been lost. Consequently, the Islamic identity of the city has been deteriorated drastically. In contrast, the old city of Bursa seems to have retained its traditional urban morphology features, especially from the point of view of Islamic urban elements so the Islamic identity of the city is preserved in an acceptable way.

Table 5. Comparative analysis of the cities of Bursa and Yazd in before and after urban modernization transformation.

		Bursa	Yazd	Result
Integration Rn	Old	0.61	0.36	The urban structure of city of Bursa is more integrated than city of Yazd in both old and new conditions.
	New	0.73	0.50	
Connectivity	Old	2.98	2.62	Increase in value of mean connectivity in city of Bursa is remarkably more than city of Yazd so road constructions in city of Bursa were more than city of Yazd.
	New	3.45	2.69	
Intelligibility	Old	0.29	0.09	Value of intelligibility decreased after urban modernization in both of these cities; it means legibility of the city cores has been decreased after urban
	New	0.10	0.07	
Meeting Place		Global position in the city core		The hierarchy orders of mean value of global integration of historic meeting places in the city of Bursa is not disrupted after urban growth and urban modernization, but this structure is completely disturbed by urban modernization process in the city of Yazd.
Bazaar	Old	0.87	0.47	
	New	0.99	0.66	
Mosque	Old	0.85	0.43	
	New	0.95	0.54	
Public bath	Old	0.77	0.39	
	New	0.94	0.56	
Religious School	Old	0.76	0.45	
	New	0.92	0.68

Environmental assessment method of urban spaces case study: south wing of the Urban Plan for Brasilia

Ederson Teixeira, Marta A. B. Romero, G. A. C. Cantuaria

Faculty of Architecture – University of Brasilia. E-mail: edersonot@gmail.com ,
bustosromero@gmail.com

Abstract. *The urbanization process tends to create many problems of environmental condition in the urban space, but not in a general way. Nowadays, there are many examples of cities that have sought an organization of the urban space in order to improve habitat conditions in public spaces. Based on this, this paper seeks to develop a method of Urban Morphology Analysis with a sustainability scope in administrative regions of the DF, and thus classify these regions according to the performance of a passive urban design. A fundamental research was developed from specific concepts from aspects of urban morphology, for when examined under a certain method, define the degree of sustainability of the region analyzed. Therefore, this work seeks to develop a new implementation methodology reducing the subjectivity of the results from in situ environmental measurements, computer simulations and studies of urban forms, using as case study the Administrative Region I - South Wing of the Pilot Plan Brasília.*

Key Words: *Urban morphology, comfort, environmental evaluation, urban spaces, South Wing*

Introduction

From the understanding that cities have individual and disparate features amongst them, and that growth brings, most often, many problems of environmental aspects of the urban space, it is understood that there is a great contrast between the notions of urban and environmental, "including the reasons why this impasse apparently does not exist in current urban planning" (COSTA, 1999:2). However, several other authors, as Romero (2000, 2007, 2011), Olgyay (2008), and Alucci Monteiro (2007), among others, argue that both concepts should be addressed in an integrated manner to ensure a better quality of urban life, both for the city, as mainly for its users.

Analyzing the concepts studied by these authors, its perceived the need to integrate the conditions of the physical space to ensure a good quality of life. However, any method of valuation that is exclusively related to the quality of public spaces is not currently available. Nowadays, various methods of building assessment, be them commercial, public, residential or services, have been developed to verify levels of energy efficiency and environmental comfort. Among these, we mention LEED, HQE, AQUA and PROCEL. In most cases, the method of measuring the results is based on the score in several attributes that check individually, parts of the building . These attributes, when brought together, define the construction quality level, from a value of its end result. However, there are few evaluation methods that have attributes to verify the level of urban quality. In most cases, the urban attributes are only related to the interference of these on the building.

Given this panorama, from a basic research we present in this work a method for environmental qualification of urban spaces, using as a basis a study developed in the course Sustainable Urbanism, of the Graduate School of architecture and Urbanism of the University of Brasilia. In this work, called Sustainable Morphological Analysis of Administrative Regions of the Federal District, specific, grouped concepts were defined in a table of indicators and attributes, defining values, which when analyzed, define the degree of sustainability of a region. However, because it is a subjective method of analysis, a difference was noted in the results, varying according to each researcher.

The indicators were conceptualized according to the studies of Romero (2007), Panerai (2006), Rueda (2007) and Lynch (1997), set out from similar characteristics of the physical space of cities. In this case, adopted the indicators studied by Romero (2011) were adopted: Accessibility, Safety, Comfort, Landscape, Social/Cultural Relations and Resources. The use of these was due to several studies conducted by the author, consolidating information from several other researchers.

The review also pointed out that the questions of urban environmental quality or, the Environmental Indicator, are analyzed briefly, being necessary an improvement of this aspect, making it one of the main objectives of this work.

Therefore, this study was divided into three basic steps. The first improved the theoretical framework involving the assumptions related to environmental conditions in urban areas, identifying attributes with well-defined concepts, gathering indicators, following the same methodology as developed in the work cited above.

With their respective attributes and concepts defined, the second methodological step begins for applying these attributes in the sectors and regions to be studied. For this it was to study the best method where there is no interference from the researcher and / or user, preferably using automated mechanisms or appropriate mathematical formulas, including computational tools to facilitate, enhance or ensure the correct relationship of the results.

Among the software used, we cite the ENVI -met, which generates a three-dimensional simulation model of urban micro climate, analyzing the surface, vegetation, atmosphere, calculating the energy balance, among other variables .

Finally, the third step consisted in the " calibration " of the proposed methodology by applying to study in an urban fraction of the Federal District (DF) . The selected region has also been part of the work of Sustainable Urbanism mentioned previously, the South Wing of the Pilot Plan of Brasilia, thus obtaining a comparison of results . The end result sets a label for sustainable urban quality whose results are compared with other studies obtained in other administrative regions of the DF . This procedure is in progress and its results serve as inputs for discussion. With these three steps finalized, we conclude the work by presenting all the achievements and future proposals for continued study.

Presentation of the work on sustainable urbanism

Initially, it was necessary a literary review of theoreticians that define concepts on urban environmental quality, such as Romero (2000, 2007 and 2011), Toledo (2003), Miller and Alucci (2007 and 2008), Ghiaus and Allard (2005), Fleet and Schiffer (2003), Carmona (2007), Duany (2001), Sennett (1991) Duany (2001), Lynch (2004), Kostof (2006), among others.

With the theoretical background acquired by reading the authors, it was possible to develop a reference table identifying the main aspects related to the environmental quality of urban spaces. Later the concepts of the authors will be unified as indicators (from the similar identification of the attributes and their parameters environmental quality). This table shows how each author examines elements that even if they are similar and related to each other, they obtain as a final result independent parameters, and adopt concepts that analyze differently urban spaces.

With the definition of these concepts, it was possible to unify them into Indicators, which aim to demonstrate the level of urban quality, highlighting the need for a critical view at the current way of life in various regions of the DF . The indicators used were the same six studied by Romero (2011) : Accessibility, Safety, Comfort, Landscape, Social/Cultural Relations, and Resources .

With the indicators defined, we developed a list of Attributes, appraising and synthesizing the data acquired by reading the authors, framing them in the seven key indicators . Furthermore, it was necessary to divide some of the renowned attributes in both scales studied by Romero (2011), the City Scale, and the Sector Scale, for being independent of specific aspects, such as the perceptual quality of the great physical and organizational form,

environmental variety, the macro transportation system, the permanence and continuity of built environment (City Scale), as well as to analyze morphological relations and their respective environmental response, environmental and functional accessibility, consistency, knowledge and functionality (Sector Scale) .

With these relationships defined, it was possible to develop a table of " Contents of Urban Morphology ", separating the attributes in their respective scales and indicators, as noted in Table 01. It is divided in two study scales: City Scale and Sector Scale. First, the indicator is set, then, the sub -indicator and analysis attributes. In this case, because it is a review, only the environmental indicator was presented .

The fourth column refers to the concept of the attribute, helping to obtain analytical view / formulas / values (valuation method of the attribute set from the on-site observation, measurement, analysis and identification maps of the study area), the fifth column. This is the main column of the table, allowing to identify the quality level from each attribute, and each result has a specific weight, which in their sum generates a value that defines the level of urban environmental quality of a given region under study . These last two columns will be better exemplified in the following item .

However, it is valid to note that these last two columns (analytical vision and weight) ended up being arbitrary, often assessed from the perception of the observer in situ, which may bias the final outcome, because by not being qualitative, may create different occurrences depending on the individual analysis of each user.

Table 1. Analysis of sustainable urban morphology - environmental indicator

City Scale					
Ind.	Sub-Indicator	Attribute	Concept	Analytical View / Formula / Values	WG
Environmental	Orientation of the paths set	Solar	Orientation of tracks predominance	I. North / South	1
				II. East / West	4
				III. Northeast / Southwest	3
				IV. Northwest / Southeast	3
	Form		Thin, open, sparse, dense, large pantry, high	I. None	1
				II. Rala, Open, Sparse	2
				III. intermediate	3
				IV. Dense Wide Cup	4
	Porosity		Visual perception of empty and full (afforestation): analysis of the vertical plane - groupings of trees	I. No porosity	1
				II. porosity secreted	2
				III. partial porosity	4
				IV. total porosity	3
	Green urban			I. No green areas (0% to 25%)	1
				II. Secreted green areas (26% and 60%)	2
				III. Green areas partial (61% to 80%)	3
				IV. Total green areas (81% to 100%)	4
	Preservation	Fields preservation	APAS, APPS, etc. Good as a territory and sustainability	I. There	1
				II. Exists, but do not preserve the fields	2
				III. There, preserve, but there is a limit of fields	3

IV. There is no limit and preserve the fields					4
Sector Scale					
Ind.	Sub-Indicator	Attribute	Concept	Analytical View / Formula / Values	Wg
Environmental	Orientation Of Dwellings	Solar	Predominant Orientation Of Facades	I. North / South	4
				Ii. East / West	1
				Iii. Northeast / Southwest	3
				Iv. Northwest / Southeast	2
	Ventilation	Permeability	Existence Of Obstacles To Ventilation	There Permeability I.	1
				Ii. Inadequate Permeability	2
				Iii. Partial Permeability	3
				Iv. Adequate Permeability	4
		Windchill	Qualification Under Relation Between The Lane Width And Height Of Buildings	I. Variable Ratio (Priceless)	1
				Ii. Claustrophobic Spaces (W / H <1)	2
				Iii. Collecting Spaces (W / H = 1, 2 And 3)	4
				Iv. Expansive Spaces (W / H > 4)	2
	Relief	Topography	Accommodation Pathways To The Contours	I. There Is No Accommodation Pathways To The Contours (0% To 25%)	1
				Ii. Favorable To The Contour Lines (26% To 60%)	2
				Iii. Favorable To The Contour Lines (62% To 80%)	3
				Iv. Favorable To The Contour Lines (81% To 100%)	4
	Acoustic Comfort	Noise Level	Noise Nuisance By Sensory Perception	I Dont Bother	4
				Ii. Intermittent Low Noise	3
				Iii. Constant Noise	2
				Iv. Loud Noise (Deafening)	1

After defining all the weights in each attribute, it was determined using an evaluation criterion based on existing certification systems. In this case, the method used for evaluation of urban areas was the criterion of points. Thus, it is possible to distinguish the difference between the assessed regions, and examine whether the region has a "low" rating, allowing you to work on specific attributes to thereby improve their grades.

Based on this, it is possible to compare the urban regions analyzed by checking the degree of sustainability of each region and its result on the Labeling Scale, thus noting which regions have better qualities for its users.

Urban environmental quality analysis

The new work methodology consisted initially in a new literature review of the main authors that deal with concepts related to environmental urban morphology. After analyzing all these concepts presented, and evaluated previously explained work and on the sum of factors that interfere with the way on how to define appropriate living conditions, it was possible to consolidate all information acquired by extracting aspects of environmental quality of each author studied. With that, we present in Table 2 the similarities and the coherence of the information, also identifying concepts that fit directly in the Environmental indicator which was reassessed.

In addition, this table 2 was the basis for recognizing which aspects are necessary to guarantee good environmental condition in urban spaces, a complement to the information already acquired in research for the course of Sustainable Urbanism.

Table 2. Synthesis

Autor	Atributos
Machado (1997)	Tastes, preferences, perceptions, values
Norberg-Schulz (1984)	Orientation, identification
Sennet (1991)	Hierarchy, identity, centrality, heterogeneity
Lynch (1997)	Legibility, imageability, paths, boundaries, districts, nodes, landmarks, shape, color, arrangement, identity, structure, meaning
Romero (2000, 2007, 2011)	Scales ratio W / H topography, vegetation, floor covering, natural and / or artificial elements that interfere with radiation and / or ventilating
Ferrari (1991)	Units Neighbourhood, size, boundaries, public areas, institutional areas, local trade, internal street system, use and occupation of land, diversity of uses
Vargas (1999)	Diversity of uses, use and occupation of land, boundaries
Panerai (2006)	Hierarchy
Rueda (2000, 2007)	Density, use and occupancy, permeable areas, mobility, accessibility, urban organization, orientability, diversity of uses, institutions, flows of energy, water, materials, comfort, degradation, automotive mobility
McHarg (1967)	Integration milestones, road connections, hierarchy of roads, cycling infrastructure, accessibility to public transportation, mixed-use pathways, equity
Rau (2003)	Public lighting, indoor-outdoor visibility (public buildings - space), environmental degradation
Jacobs (2009)	Indoor-outdoor visibility
Newman (1996)	Evaluation of the physical characteristics of the site and the natural environment, analysis of users and their needs, relationship between user needs and features of the site, pedestrian movements, boundaries between public and private ownership of space, time occupation of public spaces busy, spatial design, scale and proportion, movement, structure, artificial lighting, spatial degradation

Table 2 presents a consolidation of all information acquired during the studies on the development of this work. Seeking to improve these concepts in major groups, the six basic indicators studied by Romero (2011) were adopted: accessibility, safety, comfort, landscape, social / cultural relations, and resources.

Each indicator has specific characteristics. According to Romero (2011:42), the "nature and natural forms of the land are the basis of sustainable urban design ." She further states that "conservation allows the existence of a sense of place, their identity, sensitizing the user to the context and making more complex and continuous the perceived scale." Community social relationships create a sense of belonging and expectations of development where strategies such as social interaction, learning, continued education, magnify these concepts. Furthermore, the resources refer to "aspects of recycling solid and liquid waste in integrated systems, eliminating waste and making use of the heat generated". For this, we look for alternative energy sources, rational use, as well as solutions to environmental air quality (Romero, 2011:42) .

With these key indicators set, and separating each authors' guideline in their respective indicator, we find: Accessibility Indicator (11 attributes) ; Landscape Indicator (14 attributes); Comfort Indicator (9 attributes); Social/Cultural Relations Indicator (12 attributes); Security Indicator (4 attributes), and; Resources Indicator(4 attributes), for a total of fifty-four (54) attributes .

New method application

This step of the work consists, initially, on the understanding of the classification criteria adopted by the study conducted in the course of Sustainable Urbanism, of the Urban Environmental Quality table. These classification criteria stipulate optimal parameters acquired from the reading of the theoretical framework, and this way ensuring a degree of comparability between the areas to be studied, in this case, a review of the South Wing of the Pilot Plan of the Federal District.

Based on existing certification systems, the method used for evaluation of urban areas was the points criteria. Each item measured has a specific value ranging from 1 to 4, wherein those having a greater assessment of weight 4 are more sustainable than those with weight 1. Thus, it is possible to distinguish the difference between the evaluated areas, as well as examine whether a region is on a low note, allowing work on specific attributes to thereby improve their grades.

In addition, it was adopted in the work a reference level between administrative regions studied (in this case it was just presented the South Wing of the Pilot Plan of Brasilia). This reference level, called here "Labeling Scale" was defined as the sum of the weighted averages based on the number of attributes and their grades. The Seal B is acquired from the sum of all attributes being considered Weight 3, thus ensuring a minimum level for a Sustainable Urbanism. Have the Seal D, was given from the sum of the attributes with weight 2, and their ranges were established as Seals A, C and E.

This way it was possible to compare the urban regions analyzed by checking the degree of sustainability of each region and its result on the labeling scale, therefore verifying the urban areas that have better qualities for its users.

After the development of the labeling scale, a method was developed for the application of the table parameters, in this case only the comfort indicator. Because it is one of the more subjective indicators of work previously mentioned, this analysis sought to study this unique indicator to ensure an assessment where there is no interference from the researcher in the final result.

For this, it was necessary to continue the procedure already set, dividing each attribute into four (4) evaluation indexes, each possessing its respective weight ratio. For these indices to be agreed upon, it was necessary to discriminate all the attributes by checking the form of analysis of each attribute, thereby locking the feasibility assessment.

Among the attributes found in the Comfort Indicator, we have: acoustic, porosity, temperature, ventilation, humidity, environmental W/H ratio, topography, shading/vegetation and soil permeability. Therefore, it is observed in Table 3, the Comfort Indicator, two examples of the attribute containing the conceptualization, his method of analysis, evaluation indices with their respective weights

Tabela 3. Confort

Attribute: Ventilation	Indices:	WG:
	I. Ideal (0-30%)	1
Assessment Method: Check the result of computer simulation, the percentage of adequate ventilation in the pedestrian level.	II. Ideal (31-60%)	2
(Adopted value between 1.2-1.7 m / s)	III. Ideal (61-80%)	3
Analysis: Computer Simulation - ENVI-met.	IV. Ideal (81-100%)	4
Attribute: Permeability of Soil	Indices:	WG:
	I. Permeable (0-20%)	1
Assessment Method: Ratio of paved area and constructed with permeable area in percentage (%).	II. Permeable (21-50%)	3
Analysis: Study of Soil Permeability.	III. Perm. (51-80%)	4
	IV. Perm. (81-100%)	2

The analysis of each attribute was defined from the use of scales, studies and computer simulation. These choices seek to reduce the chances of interference from the researcher's personal assessment of the results and so may be possible to maintain a standard of comparability across sectors analyzed.

Initially, it was necessary to understand at what scale (City or Sector) to apply the study. For this, it is necessary to understand the space as a whole, observing all its features, identities, similarities and singularities .

It is noticed initially in the South Wing of the Pilot Plan of Brasilia (the case of this study), a standardization of these areas, from the routes, buildings and vegetation in almost 90 % of its area. Moreover, it is observed that urbanism adopted follows the features proposed as Neighbourhood Units (Ferrari, 1991), with residential, commercial and service buildings in an area of approximately 500m each as defined in the Pilot Plan of Brasilia as Superquadras.

**Figure 1. Simulation study of ventilation in Envi-MET software.**

Regarding the evaluation of the Soil Permeability attribute, it took place initially from the withdrawal of buildable area with paved area. Of the spare area, 70% was defined as pervious area, with the remaining 30% used as a public footpath concrete, non-permeable. Therefore, the result obtained 41.10% of permeable area (Figure 57), obtaining weight 3 as evaluation indices defined from the theoretical reading (Figure 2). It is known that the more permeable the region, the better for rainwater drainage, biodiversity, among others. However, because it is an urban area, seeking appropriate paths for all users, including individuals with special needs, excess

permeable area decreases the quality of urban space. It is noteworthy that soil type was evaluated, only the amount of possible permeable areas.

Figure 2. Soil Permeability Study.

After analyzing all the attributes, the sum of the weighted average of all weights is found, checking the degree of urban environmental quality of the region according to the labeling scale. It was noted that for the Comfort indicator, the end result was little different than previously found. However, we understand now that the new review process became independent of the perception of the researcher, applicable by any user.

Briefly, of the final table with 54 attributes defined in the 6 indicators, only 49 have a defined method of analysis. In this sense, the attributes that do not have a method of analysis set were taken from the sum of weighted average weights because their definitions are not part of the objectives of this work .

With that, and analyzing the old review of the case study with the new results obtained with the Comfort Indicator (this work), the Analysis of Sustainable Urban Morphology in the South Wing, received the Label A.

Final Considerations

The present study sought to enhance the work developed in the course Sustainable Urbanism, of the Graduate School of Architecture and Urbanism of the University of Brasilia, on sustainable morphological analysis of administrative regions of the Federal District .

Based initially on literature review on urban environmental quality, through authors such as Romero (2000, 2007 and 2011), Toledo (2003), Miller and Alucci (2007 and 2008), Ghiaus and Allard (2005), Fleet and Schiffer (2003), Carmona (2007), Duany (200), Sennett (1991), Lynch (2004), Kostof (2006), among others . From this, we sought to systematize the acquired concepts, defined here as attributes, grouping them into indicators, later to establish valuation parameters that would be used in some administrative areas of the Federal District .

With regards to the reading, it was possible to synthesize the concepts of fifty- four (54) attributes, divided into six (06) indicators adopted from studies of Romero (2007), Panerai (2006) and Rueda (2007). They are: Accessibility, Landscape, Comfort, Social / Cultural Relations, Security, and Resources.

Furthermore, it was established a method of classification, defined as Labeling Scale, where each attribute independently analyzed receives a weight, and the weighted sum so would set a

rating of " A" to " E", being "A" the label adopted for the regions with better urban environmental quality .

With this, it was sought to develop a new evaluation methodology, trying to reduce the subjectivity of the results and to be applied by any researcher. For the case study, the Comfort indicator was revised. All attributes of this indicator were studied individually, conceptualized and implemented in a new methodology for analysis from in situ measurements, computer simulations and study of maps and forms .

It was noted however that even after the new procedure, there weren't so many differences in results from the previous study, receiving in the end, the same level of labeling (Label A) .

However, it is noticed that despite the similarity of the results obtained in both studies, there was an evolution in its application methodology. Even though much of the assessment method still presenting subjectivity, this study will help other researchers to develop new methodologies for analysis and application, increasingly looking to minimize any user interference in their results.

Comparing urban rules for urbanizing villages in Hong Kong, Macau and Shenzhen

Hendrik Tieben¹, Joanna Chu¹, Nuno Soares¹, Chung Yam Yiu²

¹School of Architecture, ²Department of Geography and Resource Management, The Chinese University of Hong Kong. E-mail: hktieben@cuhk.edu.hk.

Abstract. *Since the introduction of China's Open Door Policy (1979), scholars were attracted to study Chinese urbanism in general and conduct individual case studies. The methodological approach of urban morphology has been extended to Chinese cities, and comparative studies of Chinese and Western cities were published. This paper adds another comparative study focusing on three cities in the Pearl River Delta (PRD): Hong Kong, Macau, and Shenzhen, all belonging to the People's Republic of China, but presenting significantly different urban forms. The cities lend themselves for comparative studies, as they share the location in a river delta, subtropical marine climate, Cantonese culture, and high-density, but differ significantly based on their individual histories and British, Portuguese, and Chinese planning rules. Due to China's One Country, Two Systems policy their differences persist, despite the integration process currently pushed forward by large-scale infrastructure projects. With this focus the authors' intend to link urban morphological research closer to urban design and planning practice. This paper, in particular focuses on rules, which were implemented to address issues arising from the urban expansion onto rural land. The research is supported by a General Research Fund (GRF4440740), awarded by the Hong Kong University Grants Committee.*

Key Words: *Chinese urbanism, comparative studies of urban forms, urban rules, and urban villages.*

Introduction

Based on the economic and political significance of Hong Kong and Macau's integration process into mainland China, comparative studies on the different planning cultures in the PRD have been made (for instance Ng, 2005). Also the governments of these cities made initial steps to plan an integrated "Pearl River Bay Region". These studies concentrated until now mainly on the regional scale. Detailed comparative studies highlighting the local characteristics of the different urban forms and planning experiences are still missing.

For our research project we assume that the three selected cities (like many other cities) had to address similar key urban issues such as public health, economic development, housing, informal development.²⁰⁸ For this paper, we concentrate on those rules implemented by Hong Kong, Macau and Shenzhen, to address issues arising from the cities' expansions onto rural land. Such rules had to address various issues related to different local histories, land management and ownership, compensation, housing eligibility, and redevelopment opportunities. In the discussion of the case studies these issues are used to organize and compare the different rules. The selected case study sites are: Hung Shui Kiu (HSK) (Hong Kong), Baishizhou (Shenzhen) and Taipa (Macau). These sites were selected, due to currently ongoing projects in these areas which likely will transform them very soon. These sites were also

²⁰⁸ In general, we identified the following key issues and planning goals, as reasons to implement, revise or repeal specific urban rules and guidelines in the four cities: public health and order concerns, increase of industrial, productivity and employment, response to mass migration, attraction of foreign direct investments, coping with overdevelopment, transformation from manufacturing to service and financial industry, attraction of tourists and talents, ensuring environmental and heritage protection and quality of life, encouraging creative industries, responding to citizen concerns and aspirations.

selected as studio sites for the M.Sc. in Urban Design Programme at the Chinese University of Hong Kong.²⁰⁹ Findings of the case studies are discussed in the final part of the paper.

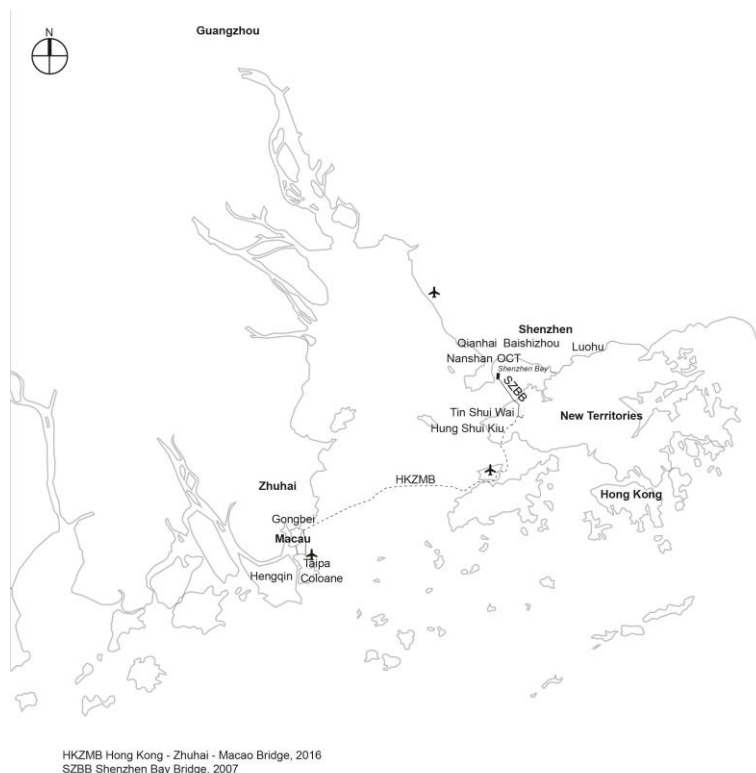

Figure 1. PRD Map with case study sites.

Cases and rules

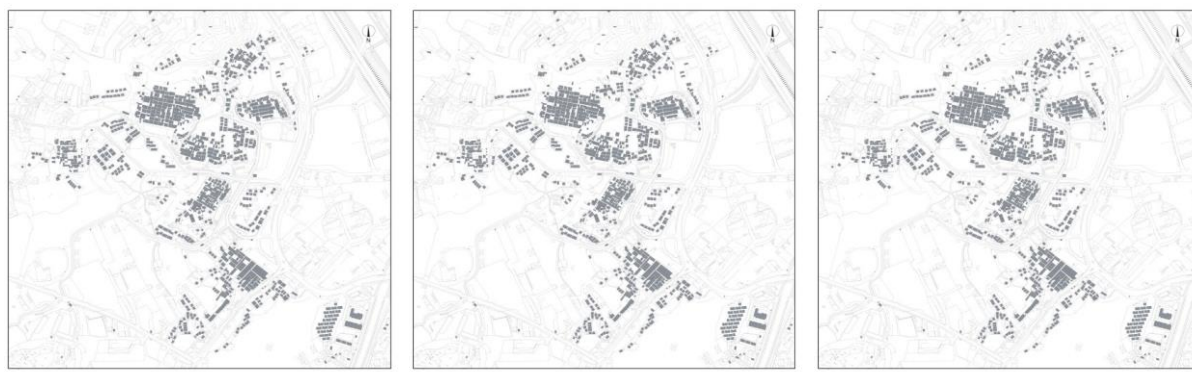

Figure 2. Case Study Sites: 1) Hung Shui Kiu (Hong Kong); 2) Taipa (Macau); and 3) Baishizhou (Shenzhen).

²⁰⁹ The parallel studios were taught by Travis Bunt, Colin Fournier, Chris Gee, Tat Lam, Nuno Soares and Hendrik Tieben. With their inputs in the studio discussions they all contributed to the idea and content of this paper. Students visited all three sites and presented their research and design projects at different stages to all classmates and teachers.

Figure 3. Urban Villages in Hung Shui Kiu (Hong Kong), Taipa (Macau), and Baishizhou (Shenzhen).

The urban rules for urbanizing villages are organized according to the following four categories: history; land management and ownership; *Compensation for Eminent Domain* redevelopment of villages.

History

The first category of rules is related to the specific backgrounds of the three villages.

The villages in Baishizhou and HSK are located in close vicinity in the north and south of Shenzhen Bay, respectively. The boundary between the north and south side of the bay, created in 1898 after the “New Territories” were leased to Hong Kong, still exists. Most villages in HSK were built by Punti which had developed into complex wealthy lineages, settling in separate villages about ½ mile from each other, and became known as “the Great Clans” during the 15-19th century. The Tang clan settled first at Kam Tin in the mid-11th century and established their settlements in Ping Shan, Ha Tsuen, Lung Yeuk Tow, and Loi Tung, which still exists today. The Tangs were the most powerful of the “Five Great Clans” in the New Territories, with Ha Tsuen, Kam Tin and Ping Shan, as their most important settlements. It is known that Ping Shan and Ha Tsuen villages fiercely competed over the ownership of the ferry over the HSK River (Hase & Sinn 1995). Originally this river arrived at Ha Tsuen, which was the most important village of the area, and is the location of the Tang clan ancestor hall. Later the river was relocated towards north-east dividing today’s HSK from the new town Tin Shui Wai (TSW). Before becoming part of the British colony, HSK was well connected via the Shenzhen Bay to the Nantou peninsula and the provincial capital Guangzhou further north. After the construction of the border this north-western part of the New Territories lost its importance and became the backyard of Hong Kong. Today its landscape is shaped by three storey “village homes”, open container storages and patches of remaining agricultural land. This landscape contrasts to the adjacent new town TSW, with its 32-38 storey residential towers, multistorey school buildings and shopping centers. TSW new town was built in 1987 over an area of abandoned fish ponds and rice paddies.²¹⁰

Based on the current housing demands and as part of Hong Kong’s regional strategy, the government plans to build in HSK one of its biggest New Development Areas (NDA) for around 160.000 inhabitants. 826 hectares are earmarked for 60.000 new homes and a logistic hub. 40 storey towers are planned around the newly planned MTR West Rail Station. The first part of the HSK NDA should be completed in 2024 (Ng, 2013). The 20 existing indigenous

²¹⁰ Around 488 hectares of land for the new town were reclaimed. A consortium Mightycity Ltd. (including investors from Hong Kong, UK and China) bought the land from the local Chan clan, and a first public-private-partnership development proposal was made in 1980. However, due to a property slump in 1982, the government declined the proposal and decided to buy the land from the developer, but re-granted 38.8 hectares of land to the developer in 1989 for a private housing and commercial development scheme (Bristow, 1989 p.220). In 1982, the government commissioned consultants to prepare a master plan for the Tin Shui Wai south development zone, and started the Tin Shui Wai New Town Development. (Law et al., 2009).

villages in HSK would not be directly affected; but, 5 of the 9 non-indigenous villages, including 1,400 squatter huts, are planned to be cleared (Ng, 2013). In addition some of the land of the indigenous villagers, currently used as container storages, will be used for the new housing areas. Thus the villagers have already compensations for these areas. A similar NDA project in the north-eastern New Territories has created vehement protests of villagers and similar resistance is to be expected in HSK.

Figure 4. Shahe Farm in 1982 (in Xia Baishi).

Figure 5. Shennan avenue in 1980s (Shennan avenue divides Baishizhou into Shang baishi and Xia baishi).

Baishizhou is located in Shenzhen, north of Shenzhen Bay between Nantou and Louhu. Most of the land next to Baishizhou is owned by the Overseas Chinese Town (OCT) Holding, which developed here China's first theme parks, luxury residential areas and "OCT Loft" (Shenzhen's main creative industries cluster). Baishizhou encompasses an area of 7.4sqkm with an estimated population of 140,000 people, of which only 7,500 residents have the Shenzhen *hukou* and only 1,880 are locals. The area is serving as residential place to those employed in the OCT theme parks and creative industries. Density reaches 18,900 p/sq.km (O'Donnell, M.A. 2013). In the same super-block, there are industrial buildings and gated communities next to the village. The Baishizhou area includes 5 smaller villages - Baishizhou, Shangbaishi, Xiabaishi, Xintang and Tangtou, which date back to the state-owned agricultural collective, Shahe Farm, established in the 1950s, when agricultural land and production was reorganized by the communist government (O'Donnell, M.A. 2013). Houses in the urban villages reach up to 15 storeys and are surrounded along the perimeter roads by new commercial and residential towers. Industrial buildings and dormitories in Baishizhou are south orientated, multi-storey slab-blocks, similar to those found in many parts of China. Currently there are discussions between OCT Holding, the village corporation and further private developers how to regenerate or redevelop the urban villages of Baishizhou.

As part of the 2003 signed Closer Economic Partnership Arrangement (CEPA) between the PRD cities, several ambitious infrastructure projects were launched (which also affect the three

case study sites). Since 2007, Shenzhen Bay Bridge has connected the western part of Shenzhen (incl. OCT, Baishizhou, Shenzhen Airport, and the new Qianhai Special Development Zone) with Hong Kong and Hung Shui Kiu. The bridge is part of a new Hong Kong-Shenzhen Western Corridor which will reach Hong Kong International Airport in the south and via the *Hong Kong–Zhuhai–Macau Bridge* the western side of the Pearl River Delta. In Macau and Zhuhai, another New Development Zone is planned on the Island Hengqin (similar to the Qianhai New Development Zone in Shenzhen). This area on Hengqin is located across the boundary of Macau's COTAI Strip and near the third case study site: Taipa Village (see map). When the *Hong Kong–Zhuhai–Macau Bridge* opens in 2016, traveling time from Shenzhen and Hong Kong to Macau and Zhuhai will be decreased significantly so that daily commuting by car would be possible. Today, new apartments in Macau are sold at comparable prices to Hong Kong, as property prices tripled since 2009. Since Taipa Island has a lower population density than Macau peninsula, and vicinity to the new casinos, Macau Airport, University of Macau and Hengqin, it is particularly targeted for upper-market real estate projects.

Like HSK, Taipa Village has always been located at the periphery (with some typical fringe-belt land-uses in its neighborhood). Taipa always had few developments for most of its history. However, due to Macau's casino boom and the ongoing integration process of Hong Kong and Macau into mainland China, this is quickly changing. According to the Macau census of 1991, the population of Taipa Island then was 7,037. This number increased to 41,786 in 2001 and to 78,497 in 2011 due to the intensive building activity taking place on the Island for the past decade.

In Taipa, we find a similar contrast in building scales like those found between HSK and TSW new town: houses in Taipa Village are still only 2-4 storeys high, while the towers of the adjacent New Taipa area reach 40 storeys.

Taipa began to be developed more intensively after the inauguration of the first Macau-Taipa bridge in 1974 (Ponte Governador Nobre Carvalho). Differently from Macau peninsula, the Portuguese presence on the island dates back only to 1847. This happened under the Governor Ferreira do Amaral, who was later killed by Chinese in response to the extension of Portuguese rule over a territory that so far had been administered by the Chinese. Amaral had pushed for a transformation of Macau into a colony similar to Hong Kong, which had been established as colony only five years earlier and quickly took-over most of Macau's trading business.

Before 1847, Taipa, originally two separate islands, was inhabited by Chinese fishermen and a few farmers and traders who lived in villages spread on the west coast of the larger island (Pedro Dias, 2005). Little is known about these villages, however, the presence of a temple dedicated to the God of War – Kuan Tai Miu – constructed during the Ming Dynasty, points to the first settlements dating of the 15th century. These villages expanded into becoming one during the 18th century, due in large part to an order issued in 1717 by the Chinese emperor by which all foreign vessels travelling towards Guangzhou should dock here before continuing towards China. The presence of foreign traders attracted new people who settled on the island taking advantage of the commercial opportunities emerging with the mandatory anchorage.

The occasion of a series of devastating fires (1853, 1858, 1878) and typhoons (1874) that affected Taipa Village during the second half of the 19th century eventually led to changes of its urban fabric. In 1867, a special administrative body was put in charge of carrying out public works on the island, such as installing electric lighting, widening and paving roads, lining them with trees, constructing small land reclamations, etc. A few public buildings also date from this period such as a market, a church and a hospital (Pedro Dias, 2005; Rodrigues Costa, 2001).

In 1869, a Town Council for the island was established and it received its civil district administration in 1879 (Rodrigues Costa, 2001). Thus the name "Taipa Village" is misleading, as its status already was that of a small town.

Following the public works mentioned above, besides the five villas that were built in 1921 as summer residences for Macanese on the southern shore of Taipa; there were little changes on the island for a few decades. From 1926 to 1974, Portugal went under the rule of the authoritarian and highly bureaucratic regime *Estado Novo* (lit. New State), which centralized

colonial administrative bodies and policy making in Lisbon, causing most urban development in Macau to be put on hold (Proença, 2007).

This changed in 1971, with the completion of the preliminary stage of Macau's first Master Plan to include the islands (*Plano Director de Macau*, developed by *Grupo de Trabalho de Planeamento de Macau*). Even though this plan was never carried on to further design stages, nor was it officially published but many of its strategic principles were adopted in the following decades. The plan previewed distinct roles for each of the three territorial units: while Macau was in urgent need of expansion in the short run, Taipa was envisioned as a long-term expansion area and Coloane was regarded as a touristic destination only. The plan established large land reclamation areas both for the Peninsula and for Taipa, meant to accommodate the high demographic growth that was taking place since the 1950s. It also established strategic lines for the development of a transport and infrastructural network; including the Macau-Taipa bridges and the International Airport in Taipa (Proença, 2007).

In 1987, the Sino-Portuguese Joint Declaration determined the conditions of the handover of Macau's sovereignty from Portugal to China (three years after the Sino-British Joint Declaration for the handover of Hong Kong's sovereignty to China). The signing of this agreement resulted in an acceleration of public works for Macau as a whole. At this time the project for University of Macau was established in Taipa, acting as an important catalyst for its development. 1987 was also the year when the first plans for the new town project "New Taipa" were presented. Thus the planning of this new town came after the first ideas for Hong Kong's new town TSW (see above). One year later, in 1988, the firm Asia Consult prepared the "General Plan of Taipa" (Rodrigues Costa, 2001).

The opening of two new Macau-Taipa bridges - Ponte da Amizade (1994) and Ponte Sai Van (2004) -, the inauguration of the international Airport in 1995, and the construction of the COTAI strip around the Taipa-Coloane Isthmus (first opened in 1963) in the early 2000s, set the ground for Taipa's most recent accelerated development. It was in COTAI that, following the opening of Macau's gaming monopoly in 2002, several of the world's largest casino resorts were constructed. If we compare Taipa Village with Baishizhou, it is remarkable that next to the 40 storey towers of New Taipa and the 980,000 sm Venetian Macau Casino Resort, yet the small fabric of Taipa Village remained unaltered.

Land management and ownership

The different organization of land ownership is another key factor influencing the different urban forms of the three villages. The indigenous villages in HSK were constructed on land belonging to clans. Basically two types of land ownership in the New Territories existed, one privately owned and the other collectively owned under the name of a T'so (祖) or a T'ong (堂)²¹¹. It is a Chinese customary trust over land to maintain and preserve the clan's properties in the village, for various purposes. It is estimated that there are about 7,000 T'so/T'ong established in the New Territories. They are governed by the New Territories Ordinance (Cap. 97) stating that an appointed manager of the T'so/T'ong shall be registered. For example, in the HSK case, it was reported that there were 100 ha T'so/T'ong land out of the 826 ha of acquired land from the villages, while the privately owned land was about 511 ha.

Over the years, rural land surrounding the original villages was transformed in various stages: Villagers sold their rights to build small houses to developers, which then developed larger units with up to nine houses (Cody & Richardson, 1997). These developments can be recognized as loosely grouped clusters outside of the tightly organized village cores (Figure 5b). Other houses were sold individually and can be recognized by individually fenced-in gardens

²¹¹ A t'so normally originates from an ancestor who did not want his land to be divided among his descendants, but to be preserved perpetually and collectively for various uses. A t'ong is similar but not originated from an ancestor. It can be a collective decision to form a t'ong to preserve the land for various purposes such as education, business or religious purposes.

(Figure 5c). Over the years, much of the village land in the New Territories was bought-up by Hong Kong's powerful property tycoons, who hold here large land banks as to control land supply and invest in future developments. But their land ownership in the area remains hidden and is not represented by plot boundaries and building footprints.

Figure 6. Village houses in Hung Shui Kiu with changing land ownership relationships.

Land in Baishizhou, as in other parts of China, is generally subdivided into two categories: 1) Land owned by the government and state owned enterprises and 2) Village land managed collectively by village corporations. In the 1950s under the new communist government, the state-owned agricultural collective, Shahe Farm, was created. After establishment of the Shenzhen Special Economic Zone, it was transformed into the different villages of Baishizhou.

In 1987, Shenzhen started to experiment with a land-lease system inspired by Hong Kong, however with the difference, that in Shenzhen (and China) only land-use rights could be acquired, while land-ownership remained unchanged. This option was confirmed in 1988 by a revision of the Chinese constitution. In only a few years, a vibrant real-estate industry developed in Shenzhen (Lü et al., 2001). Today, in Baishizhou the most important stakeholders are the village corporations, OCT Holding and further private developers, who are responsible for different parts of land within the super-block.

An essential difference, between the villages of HSK and Baishizhou, with their collective land ownerships and Taipa Village in Macau is, that after its repeated destruction through fire and typhoons in the late 19th century, it was reconstructed with a network of public streets, street blocks, and individual plots. Thus, although it has similarly small alleys and houses like the other two villages, it has clearly defined boundaries between public spaces and private plots (Figure 7).

Figure 7. Selection of street blocks and building types of Taipa Village (left) and the surrounding public and private housing developments in its direct surrounding (right).

With Macau's growing role in tourism, Macau's municipal office conducted several projects to regenerate these public spaces. In contrast, the open spaces of the villages in HSK and Baishizhou are collectively owned and have ambiguous boundaries between the collective and private spaces. This contributes to various issues related to public safety, sanitary conditions, and illegal constructions. The different conditions of Taipa Village, were likely related to the

adjustments made after the destructions. However, despite these changes, the intimate scale of the village was kept.

Figure 8. Population Growth Comparison.

Compensation for Eminent Domain

A major issue in the urbanization process of rural villages is arrangements of compensation for the loss of rural land.

In the first years after the establishment of the Shenzhen Special Economic Zone (1980), the government could easily expropriate rural land for new developments. At that time villagers were not compensated for the loss of rural land, but could usually continue to live in the area. The 1982 *Interim Regulations of Building Land of Villages in Cooperative in Shenzhen SEZ* allowed each household to build a residential dwelling of max 80sqm with a max floor area of 150sqm on 2-3 floors. At that time, villagers built the houses as their own homes. This changed soon with Shenzhen's rapid economic growth. From 1984 onwards, villagers increased the building heights to 3-5 floors, using only one unit for themselves and renting out the other units to migrant workers (Wang, 2013).

Figure 9. Selection of building types in Baishizhou arranged according to building age.

In 1989, the *Provisions of Land Expropriation in the Shenzhen Special Economic Zone* was implemented to protect parts of the rural land for “law-protected villagers” residential lots, as *Housing Based Land (HBL)*. In addition, parts of the expropriated land were returned to the villagers as compensation for their lost agricultural land. This land could be used for commercial and industrial developments, as *Land for Collective Development (LCD)* and would be managed by the newly established collective village corporations (Wang, 2013).

Villagers could now gain profits in two ways: rental-income and collectively managed commercial and industrial developments. According to the regulations for *Housing Based Land*, new plots were organized in a grid of 10m x 10m with narrow alleys (Figure 10).

In Baishizhou, we can find such houses built after 1989, however the grid layout and building dimensions are more irregular, creating labyrinthine spaces. In addition we find industrial

developments in the middle of the block, which according to the new rule of 1989 could be collectively planned by the village corporations. Based on the farmers' dwelling policy restriction, villagers in Shenzhen could not sell properties. Thus their main way to raise their income was to increase building heights and build more houses. Also as unbuilt areas in the villages were more likely to be expropriated by the government, villagers had an interest to cover the entire area with buildings. This resulted in the extremely narrow, dark and dense spaces in Baishizhou and other urbanised villages in Shenzhen.

Figure 10. Compensation rules for villagers of urban villages in Shenzhen.

Reflecting upon the rules Hong Kong government implemented to address the high demand for land for the accommodation of migrants and the construction of factories in the decades following World War II, we can identify different rules from those in Shenzhen. The first migrants who arrived either were absorbed by the urban areas, where in the 1950s height restrictions were loosened, and buildings quickly grew taller; or they settled in improvised squatter areas along the hills, which the government demarcated. With the decision to extend urban development with new towns into the New Territories, as suggested by Abercrombie in 1948, landowners in the villages (elders or their sons) became interested in selling or leasing some of their property to private developers. In 1960, the government devised a way of acquiring rural land in the New Territories and responded to the interests of villagers and developers by implementing a program of transferable development rights: for every 5sqft of agricultural land surrendered 2sqft of building land were allocated (in the form of a certificate for future redemption). In contrast to Shenzhen, villagers in Hong Kong's New Territories could sell the new development rights on the open market, much of which were bought by developers. A new policy, known as Letter A/B system, provided villagers with a marketable certificate tied to specific development parcels in the new towns.²¹² The rule was especially used in centrally located and earlier developed parts of the New Territories such as Shatin in the 1960-70s. Today, this option is no longer used in HSK. The rule which instead shapes the urban landscape here is the Small House Policy (Cody & Richardson, 1997).

This policy was launched in November 1972. Under it, indigenous male villagers, who are over 18 years old and are descended through the male line from a resident in 1898 of a recognized village, are entitled to one concessionary grant during his lifetime to build one small house. The policy allows indigenous villagers to build small houses, no matter if they own land or not²¹³, provided that they are built in existing village areas within 91.44 metres (300 feet) from the edge of the last house built before December 1972, or within village type development

²¹² Each new town had several parcels of urban development land for redeemed Letters A or B certificates, developers bid to develop Letters A/B parcels by purchasing required number of certificates in the open market. Under the conditions of the 1984 Basic Law Agreement between Great Britain and China, after July 1 1997, the Letters A/B certificates were no longer operative (Cody & Richardson, 1997).

²¹³ (a) For an indigenous villager who owns private agricultural land, he can apply for a building licence at nil premium, or a land exchange to build a small house on his own agricultural land; or (b) For an indigenous villager who does not own land, he can apply for the grant of a site on government land at a concessionary premium of two-thirds of the full market value.

zones in Development Permission Areas or Outline Zoning Plans. The small house is regulated by a height limit of 3 storeys or 8.23 metres (27 feet) and 65.03 sqm (700 square feet) in the roofed-over area (Figure 11).

Height and Roof Area (post 1905)

Height means the perpendicular height measured from the lowest point at ground level to the highest point of the roof. In determining the highest point of the roof, no account should be taken:

Height and Roof Area (post 1972)

Height means the perpendicular height measured from the lowest point at ground level to the highest point of the roof. In determining the highest point of the roof, no account should be taken:

Figure 11. Urban rules in Hong Kong's New Territories including the 1972 Small House Policy.

Since then, a process of suburbanization started in the New Territories. All new private buildings had the same small dimensions and were scattered on the village land without an overall planning process.

In Hong Kong, this rule was a welcomed entitlement for those who qualified, and was generally followed. However, in Baishizhou, the rules implemented by the government to compensate villagers and restrict illegal constructions were usually soon ignored after implementation. According to V. Wang, the inability to provide enough land for development, pay the full compensations promised to the villagers and provide enough accommodation for migrants, made it difficult for the government to enforce their own rules. Villager used this weakness to extend their houses to 7-8 storeys since the 1990s, as demand for rental spaces continued to grow. Later, implemented rules such as the *Bylaws of Housing Rental in the Shenzhen Special Economic Zone* and *Bylaws of Registration of Real Estate in the Shenzhen Special Economic Zone* remained without effect (Wang, 2013). In Baishizhou, some of the village buildings reach up to 15 storeys.

Figure 12. Development units of Taipa Village and its surroundings

In Taipa Village, the situation is very different from the other cases. Most inhabitants here were fishermen or tradesmen and didn't own significant amount of farmland, for which there was also little space given that the village was surrounded by hills and water. New constructions for public and private housing were built on reclaimed land, and thus needed no costly and long negotiations. This also benefited the government, which like Hong Kong uses a land-lease system and benefits from the production of new land, if the building density is high enough to recover the reclamation costs. In contrast to HSK and Baishizhou, villagers in Taipa had no basis to bargain for compensation. On the other hand, they were not driven out from their private properties either.

Figure 13. Shadow rule, Taipa village.

Although Macau experienced several waves of immigration, Taipa Island wasn't affected for a long time. Until 1974, the only way from Macau to Taipa was by ferries. After the construction of the bridge connection, new constructions remained limited to middle to upper class housing, except a smaller public housing project built adjacent to Taipa Village in 1992. This project was part of a larger social housing programme that took place in Macau as a whole, between 1985 and 1992, to house low-income residents of the territory. However, generally job opportunities for low-skilled workers remained on Macau peninsula. This only changed with the construction of the new casinos after 2002. The small dimensions of houses in Taipa Village remained determined by the small plot sizes and the Shadow Rule, established in 1985 by the General Regulation of Urban Construction, which defined building heights by a 76 degree angle measured from the middle of the street (Figure 10). As streets and alleys in the village remained narrow, the building height also remained low. The same rule, however, allowed in New Taipa high walls of towers based on the wider roads and open spaces in this area.

Redevelopment

The HSK NDA, will not directly affect the settlements of the indigenous villages, but residents are afraid of unemployment and loss of income in form of rent, if the surrounding container storages would disappear to make space for the new housing development. In addition there are concerns of the indigenous villagers eligible to small houses, if they still will be able to find spaces to build them. Also there is some frustration on their side that it is not allowed to build larger buildings.

On the other hand there are also those concerns of people in Hong Kong, which cannot find affordable living space and have to live under very congested conditions. The Small House Policy continues to make efficient land use in the New Territories difficult, resulting in the paradox condition to have large areas with scattered settlements of three storey "village homes" and next to them, high density new towns, like TSW, with over 30 storey towers.

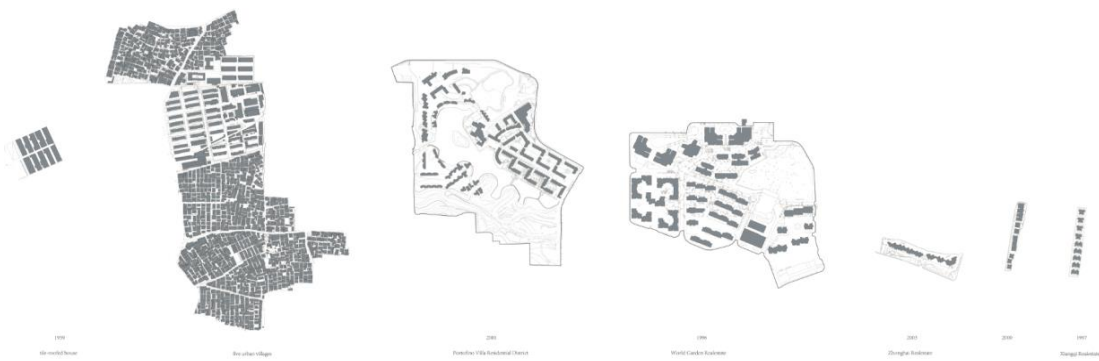

Figure 14. Development units of Baishizhou.

In Baishizhou, the villages are already surrounded by new developments, which tend to be gated up-market residential estates. In 2005, the government implemented the *Comprehensive Planning Guidelines for Urban Villages Redevelopment 2005–2010* as another attempt to show its determination to solve what they identified as the fundamental problems of urban villages and free up land for development. Villages in Shenzhen which have been redeveloped, usually had a significantly higher density than before, as to make-up for the much higher compensation claims of the villagers. In Baishizhou, the low rental prices in the villages allows workers and young university graduates to remain in the central areas nearby the employment provided in the Overseas Chinese Town.

In Taipa, the municipal government has implemented several improvements to these public spaces in the recent years, treating them in a similar fashion to those heritage urban ensembles of the Historic Centre of Macau (UNESCO 2005). This has contributed to the inclusion of Taipa Village in Macau's tourist routes, which is now emphasized by the recent construction of a footbridge connecting Taipa Village to the COTAI, particularly, to The Venetian Casino Resort. As a consequence, shop rent in Taipa Village are increasingly high, which is contributing to a gentrification process. In addition, the improved public spaces are taken over by tourist groups.

Conclusions

Major differences in the urban forms between the three cities are found to be related to historical conditions and urban rules: In Shenzhen, and generally mainland China, the essential difference between inhabitants with local and non-local registered households (“*hukou*”) was a key factor for the growth of urban villages as most incoming migrants were excluded from the housing produced by the government and state-owned enterprises and there was no formal private housing market. As the government had difficulties to provide promised compensations to villagers and couldn't address the housing needs of migrants, they accepted a twist of the rules by the villagers to build more and taller buildings, resulting in a further increasing density and potentially higher compensation claims of the villagers. On the other hand, when compared with squatter settlements in other fast growing parts of the world, Shenzhen's urban villages also have substantial advantages: they are centrally located and offer access to jobs, public transport, electricity, commercial facilities and to certain degree, clean water. In a region with frequent typhoons and flooding, they also provide a relatively safe environment, when compared to Hong Kong's early squatter settlements, which were often destroyed by natural hazards and fire.

Hong Kong's Letter A/B schemes since 1960 and the Small House Policy for indigenous villagers since 1972 have resulted in a clear separation between villages and new towns, and have shaped the uniformity of village houses in the New Territories. The Letter A/B schemes helped to shift development rights to new town areas and ensure more comprehensive new town

planning. In the meantime, despite the achievements of Hong Kong's resettlement and public housing programmes, urban poor and migrants, who don't qualify for the public housing, continue to live under appalling conditions in cagehouses and "coffin homes" (subdivided flats). Taipa Village, despite having kept its original urban fabric, serves mainly as tourist spot today, and ironically, the height limitation rule that managed to keep its original form limits its potential as for further growth as a place for living.

A study of urban space form in areas with different economic development level: a case study of Jiangsu province

Xiong Guoping, Cao Bowei

Department of urban planning, Southeast University, 2 Sipailou, Xuanwu district, Nanjing, China, 210096. E-mail: xionggp@vip.sina.com

Abstract. *The unbalance in provincial economy is a common phenomenon in China. It is an urgent task to take different urban development measures according to different areas' economic levels to achieve an integrated provincial development. With south, central and north Jiangsu areas of Jiangsu Province as an example, this article studies the urban space forms in different economic development level area, and points out that north Jiangsu area takes a point-like cluster dominated by Xuzhou, Huaian, Yancheng and Lianyungang; central Jiangsu area takes a belt-like cluster dominated by Nanjing-Nantong traffic axis; and south Jiangsu area takes a net-like cluster with Nanjing region and Suzhou-Wuxi-Changzhou region as the dominant. The evolution dynamic mechanisms vary greatly in the areas with different economic development levels. The industry structure dominates the traffic corridor pilots and the science and technology guide urban space form. For the areas with different economic development levels, different measures should be taken to optimize urban space form. South Jiangsu area should stress giant city construction and promote regional integration; central Jiangsu area should mainly construct riverside and seaside urban development belt to realize integration of south and central Jiangsu areas; and north Jiangsu area should focus on the construction of urban groups with some central cities as the core to achieve regional development.*

Key Words: region; urban space form; economic development level

Foreword

In China, it is a general situation that there exists an unbalanced provincial economic development. Since the 1980s, due to the shortage of finance, technology and market resources, each province has centered its resources for the development of areas with favorable conditions, leading to the aggravation of unbalanced urban economy. In 2014, the ratio between the first place and last place of urban GDP per capita in Anhui, Fujian, Jiangsu, Shandong and Zhejiang is respectively 2.8, 2.0, 3.5, 6.4 and 2.2. The unbalance in provincial economy has become an increasingly obvious issue, as proved by the contrast between Zhujiang Delta Region and north Guangdong area, Jiaodong Peninsula and southwest Shandong area, and the difference between south, central and north Jiangsu Province. The issue of income disparity, social conflicts and provincial infrastructure and resource overall planning difficulty and the deterioration of the ecological environment brought by the unbalance in provincial economy have posed a threat to the sustainable provincial economy development. As the need of a coordinated provincial development is becoming more and more urgent, different development policies should be acted for areas with different economic development levels. For instance, Jiangsu Province has proposed a joint development and cooperation between south Jiangsu area and north Jiangsu area, and Guangdong Province has advocated the integration of Zhujiang Delta Region and the mountain area as well as the flank areas. With Jiangsu Province as a case study, this study is to explore the inherent link between economic development level and urban space form and propose some measures to optimize the provincial urban space structure so as to promote a coordinated and orderly development of provincial economy.

Literary Review

In terms of the urban space form features of areas with different economic development levels, some scholars think that for the under-developed area, it is lacking in regional big cities, the cities and towns are far away from each other without organic connection, the cities are in point-like dispersion, and this kind of area is in the early period of regional development. For the moderately developed area, it bears more advanced regional transportation. The towns are in a belt-like spreading along the axis with help of communication axis and the exterior space of the towns takes an olive shape. The major axis of the olive goes along the polymerization axis, presenting a homogeneous belt shape (Haggett and Cliff, 1997). For the developed area, the balanced development of cities and towns accelerates the growth of central cities and secondary cities within this area. This area bears a multi-core space structure, the cities and towns form a continuous belt-shape polymerization axis with close interconnection, the polymerization axis connect each other, and displays a continuous network structure (John Friedmann, 1986; Sassen, 1991).

As to the evolution dynamic mechanism for the urban space form of areas with different development levels, some scholars point out that the under-developed urban form is under heavy influence of the natural resources distribution and the point-like dispersion of these cities are essentially coincident with the regions bearing advantageous land conditions or rich resources (Boume and Simmons, 1978); in the middle stage of industrialization, the point-like dispersing cities will be connected by traffic lines and develop gradually along the main traffic axis to form a polymerization axis; the economic development will promote the construction of new traffic lines, the increase of which will strengthen the relation between the cities, thus there will be an interactive development between cities and traffic axis (Che Qianjin, 2011). Based on the study of Europe, some other scholars find that by the time of post-industrialization, with the growing influence of technology, information network, ecological environment as well as the strengthening of relation among the cities, cities and regions, the concept of city will gradually evolve into urban agglomeration (Wegener, 1991; Castells, 1989).

As for the optimization of the urban space form in areas with different economic development level, scholars have put forward different ways. The economically underdeveloped areas should actively cultivate central cities and create regional growth poles (Boudeville, 1972; Lasuen, 1973). The moderately developed areas should strengthen the role of traffic axis, and takes the linear development mode of connecting several metropolises through the highly developed modern transportation line (Ginsburg, 1961; Whebell, 1969). The economically developed areas should take the development of track communication and large capacity public transportation as the leading force, and construct a multi-center and intensified urban-rural integrated development of regional space structure (Zhang Jiarui, 2012).

The existing research is mainly focusing on the regional development of the developed countries, while little attention is paid to the fact that the developing countries are undergoing a rapid urbanization and the regional disparity is widening unceasingly. There has been rare research on the maintenance of balance during development. This article will study the urban space form of the areas in Jiangsu Province with different economic development levels.

Theoretical Method

Jiangsu Province lies in the east coast of China covering a land area of 102,600 square kilometers. It governs 61 counties (districts). In 2013, its residential population was 78.6 million and the per capita GDP was 12,047 US dollars.

Figure 1. Location of Jiangsu Province.

Methods to classify areas with different economic levels

This research selects six indicators including the GDP non-agricultural rate, per capita revenue, per capita social retail goods, per capita GDP, rural residents per capita net income, labor force non-agricultural level, conducts a Q cluster analysis, and classified the whole counties (districts) into three layers according to their economic development levels. Based on this, the data of every group is transferred into ArcGIS to obtain the spatial distribution of each group and categorize Jiangsu Province into the developed area, moderately developed area and under-developed area.

Methods to extract urban space form

The unsupervised classification is conducted after the strengthening of the satellite photo map image of Jiangsu Province, and the results are re-categorized into buildings, roads, water body, forest, lawn, farmland and open land. Then the hot pixel suppression measures are taken for urban built-up area which is transformed into ArcGIS. Systematic samplings are collected with 1kmX1km grid to determine that the urban land area within the grid bigger than the average 1 standard value is used for urban construction, and the others are for the non-urban construction. In so doing, the image of provincial urban space structure is obtained.

Data sources

In this research, the indicator data like the per capita GDP, per capita revenue, per capita volume of domestic retail sales of commodities, rural residents per capita net income, non-agricultural rate of GDP, and labor force non-agricultural level originates from Jiangsu Statistical Annual 2013. The statistical standard is consistent and has the comparability. And the remote sensing data extracted for the urban space form is based on NASA's landsat8 remote sensing data, the image photography time is set in April, 2014, and the data is downloaded from US USUG Website (<http://www.usgs.gov/>).

Result

Obvious gradient of provincial economic development

Three groups of clusters can be obtained after the indicator data like per capita GDP, per capita revenue, per capita social retail goods, rural residents per capita net income, non-agricultural

rate of GDP, and labor force non-agricultural level of the 61 counties (districts) of Jiangsu Province are introduced into SPSS and a Q cluster analysis is made. The per capita GDP of each group of counties (districts) is 14,675, 8,048, 5,159 US dollars respectively, corresponding to the developed area, moderately developed area and under-developed area (Table 1).

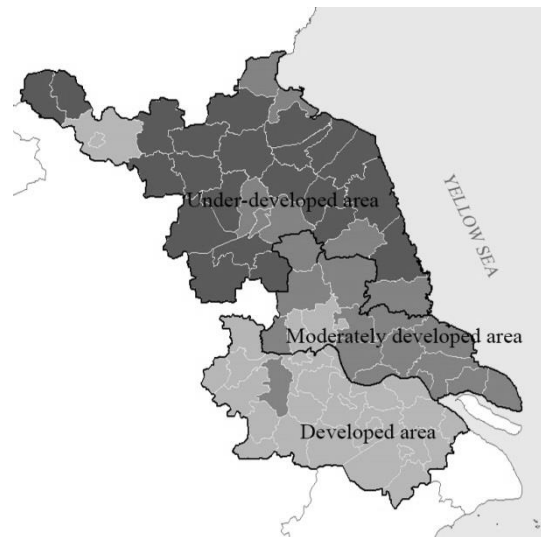

Figure 2. classify areas with different economic levels.

Table 1. Stratification of County (District) Clusters.

Type	Name of County (District)
Developed Area	Wuxi, Jiangyin, Changzhou, Suzhou, Changsu, Zhangjiagang, Kuanshan, Taichang, Nanjing, Lishu, Gaochun, Yixing, Xuzhou, Liyang, Jintan, Yangzhou, Zhenjiang and Danyang
Moderately Developed Area	Nantong, Lianyungang, Jingjiang, Haian, Rudong, Qidong, Rugao, Haimen, Ganyu, Huaian, Hongze, Jintan, Yancheng, Dongtai, Baoying, Yizheng, Gaoyou, Jurong, Taixing, Jiangyan, Suqian, Taizhou, Yangzhong, and Xinghua
Under-developed Area	Feng County, Pei County, Suining, Xinyi, Pizhou, Donghai, Guanyun, Guannan, Lianshui, Xuyi, Xiangshui, Binhai, Funing, Sheyang, Shuyang, Siyang, Sihong County, Jianhu and Dafeng

Displaying the space distribution of the three groups of counties (districts) on the map through ArcGIS, it can be found that the economic development level of the counties (districts) of Jiangsu Province indicates a gradual decrease of economic development from south to north with a spatial concentration characteristic. The developed counties (districts) concentrate in south Jiangsu area cities like Suzhou, Wuxi, Changzhou, Zhenjiang and Nanjing; the moderately developed districts (counties) concentrate in central Jiangsu area like Nantong, Taizhou and Yangzhou; and the less developed counties (districts) concentrate in north Jiangsu cities like Lianyungang, Xuzhou, Suqian, Huaian and Yancheng. The disparity between different areas manifests greatly in three indicators, i.e. per capita GDP, per capita revenue, and per capita social retail goods. The ratio between the developed and moderately developed areas is 1.93, 1.92 and 1.67, while the ratio between the moderately developed and under-developed areas is 1.55, 1.51 and 1.92. That is to say, the entire ratio is bigger than 1.5, which shows that the economic development level displays a gradient feature.

Table 2. Economic Data Comparison between Different Areas

Area	GDP Per capita (\$)	Revenue Per capita(\$)	Social retail goods Per capita(\$)	Rural residents net income Per capita (\$)	GDP non-agricultural rate (%)	Labor force non-agricultural level (%)
Developed area	14,675.2*	1,357.8	15,536.4	2,569.2	96.4	89.8
Moderately developed area	8,048.5	707.8	8,048.5	1,928.6	88.5	73.3
Under-developed area	5,159.5	470.2	5,195.1	1,607.8	81.1	59.5

* According to WB, per capita 12616 US dollar is of developed country level

Table 3. Economic Data Comparison between Different Areas (Standardized)

Area	GDP Per capita (\$)	Revenue Per capita (\$)	Social retail goods Per capita(\$)	Rural residents net income Per capita (\$)	GDP non-agricultural rate (%)	Labor force non-agricultural level (%)
Developed area	1.62	1.61	1.57	1.26	1.08	1.21

Striking difference of urban space form in areas with different economic level

Net-like cluster in south Jiangsu dominated by Nanjing, Suzhou, Wuxi and Changzhou

South Jiangsu area has formed a continuous net-like space structure led by two city regions, Nanjing City region and Suzhou-Wuxi-Changzhou region. It is at the mature stage of urban space development. Within the Nanjing City region, the core city status is obvious, the core city establishes a close link with the peripheral cities, there is a clear tendency of inter-city public transportation, and a high level highway network is basically formed with Nanjing as its core. The main cities lie on the radiation channels, and a net-like cluster based on transportation network has almost been formed. The Suzhou-Wuxi-Changzhou region has evolved from its early axial development to the current network development; the cities group has displayed a balanced development trend. In the suburbs of these cities, there have appeared some districts, which become the new space for the city expansion, and the city space has presented a multi-core and homogeneous network structure.

**Figure 3. Urban Space Form of the Developed Area in Jiangsu Province.**

Belt-like cluster in central Jiangsu dominated by Nanjing-Nantong traffic axis

The cities and towns on north side of Yangtze River in central Jiangsu area appear a belt-like cluster along the Nanjing-Nantong traffic axis and Yangtze River. With the completion of several Yangtze River channels, the cities and towns along the Nanjing-Nantong transportation axis will be affected by the radiation from the cities and towns on south riverside, especially those cities near the cross-river channels. As the development of lateral axis belt accelerates, the longitudinal axis of development comes into being.

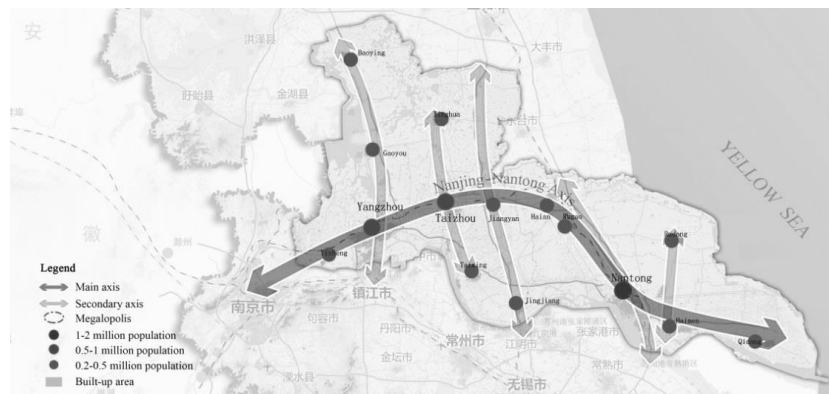

Figure 4. Urban Space Form in the Moderately Developed Areas in Jiangsu Province

Point-like concentration in north Jiangsu dominated by Xuzhou, Huaian, Yancheng and Lianyungang

The connection among the cities and towns in north Jiangsu area is fairly weak. In some regions with outstanding transportation advantages, the cities and towns begin to develop on the basis of transportation and a point-like space structure dominated by Xuzhou, Huaian, Yancheng and Lianyungang emerges. For instance, within Xuzhou metropolitan circle, there have appeared a space organization pattern, namely, one core city, Xuzhou; two city development axis, Xuzhou-Lianyungang and Zaozhuang-Xuzhou-Suqian axis; and a city connection channel, Suqian-Feng County-Pei County. In a circle at a radius of 300 km with Xuzhou as its center, the space connection is divided into the close-connected circle layer, economic cooperation circle layer and loosely-connected circle layer.

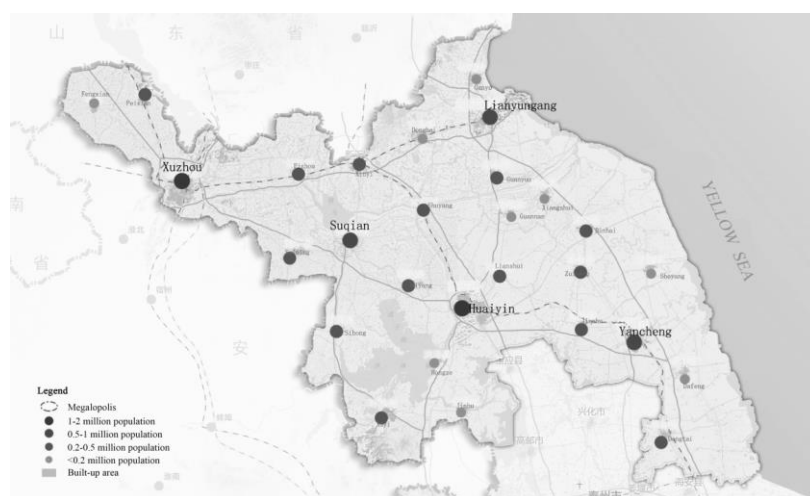

Figure 5. Urban Space Form in the Under-developed Areas in Jiangsu Province.

Different Evolution Dynamic Mechanism of Provincial Urban Space Form

Industry form dominates urban space form

Cities and towns are the base and backbone of industry development and industry is the source of urban development. The expansion of urban scale and the enhancement of urban status will provide better conditions for the development of industry, while the development of industry and the cluster of space will affect the urban development and spatial structure. South Jiangsu area strives to develop high and new technology industries, and some modern manufacture bases dominated by high and new technology have been formed. With the functions spreading of several cities like Nanjing, Suzhou, Wuxi and Changzhou, an industry structure network has been gradually established, and the development of each jointing city and towns has displayed a trend with homogeneous quality and spatial network. In some cities in central Jiangsu area like Yangzhou, Nantong and Taizhou, the technology-intensive industry clusters like petrochemical industry, fine chemical industry, superior automobile industry and household electrical appliances have been formed. The transportation-oriented heavy industry and manufacture industry has led to the formation of industry axis structure, which further promotes the belt cluster of urban space form. For north Jiangsu area, during its “Four Alongside Develop” strategy and the construction of “Three Latitudes and One Longitude” industry belt, the construction of the industry belt along the east Longhai Railway is highlighted, however, due to its disadvantageous base, the industries take a point-like form, which leads to the formation of point-like urban space form.

Traffic corridor pilots urban space form

The two core city regions, Nanjing region and Suzhou-Wuxi-Changzhou regions, in south Jiangsu area enjoy relative mature traffic network. A high level road net with Nanjing City as its core has been formed and the major cities spread along the radiation channels, among which Nanjing-Zhenjiang, Nanjing-Yangzhou and Nanjing-Wuhu are the main axis with advantageous development momentum. Suzhou-Wuxi-Changzhou region bears an inter-linked space structure, and for its systematic traffic network, the fluidity among its inner elements has been strengthened. As to central Jiangsu area, the cities and towns along the two highways, Nanjing-Nantong and Nanjing-Shanghai highways, especially those at the traffic hubs have developed rapidly, and the point-axis system has been increasingly improved. Among them, based on the development of traffic corridor composed by Nanjing-Nantong Highway, Nanjing-Qidong Railway and Yangtze River, Nanjing-Nantong traffic axis contributes to the planning of riverfront basic industry belt. The urban space structure in north Jiangsu area takes a point-like pattern, the cities and towns develops along the traffic corridor composed by Beijing-Shanghai Highway, Xinyi-Changxing Railway, Huaian-Yangzhou Railway, Beijing-Hangzhou Grand Canal, Tongjiang-Sanya Highway, Nantong-Ganyu Canal and the seaports, East Longhai Railway, and Xuzhou-Lianyungang Highway. Each city and town is independent, the number of small towns is numerous and the scale of the major cities is limited.

Science and technology guides urban space form

The economy of south Jiangsu area is fairly high and the level and quantity of the higher education establishments and scientific research institutions within this area has the outstanding advantage. The economy in this area is based on the advanced and new technology. With Nanjing, Zhenjiang, Changzhou, Wuxi and Suzhou as the joint cities, the cities and towns on the urban belt have robust economy, and the industry is shifting towards advanced and new technology industry. This area is the concentration place for the electronic information, biological engineering and new medicine, new material and new energy. It has a big density of

cities and high level of economy development, and the export-oriented degree of the cities and towns is growing. In many cities of this area, various types of technology industry parks, science establishments, college towns have been constructed to meet the need of adapting to the advanced and new technology and the rapid development of information economy. The advanced and new technology has become the dominant force for the development of the city marginal space. Due to the limitation of economic development level, the influence of science and technology is yet distinct.

Optimize urban space form according to local conditions

Promote the integration of south Jiangsu area and improve network development of space form

Promote the integration of south Jiangsu area and the integrated construction of urban and rural areas, and build grand urban region in south Jiangsu area. Upgrade the function of major cities, and develop actively the medium-size and small-size cities. Build multi-level functional complementary city areas, realize regional urbanization, and establish a structure with proper distribution, mutual connected and functional complementary of major-size, medium-size and small-size cities.

Figure 6. Optimization Measures for Urban Space Form of the Developed Area.

Strengthen urban traffic corridor in central Jiangsu area and construct the riverside and seaside urban development belt

The cross-river channels in central Jiangsu area has promoted the shift of industry from south to central Jiangsu area, provided a new environment for the development of advanced and high technology industries in south Jiangsu area, and created channels for the introduction of market space and capital for the riverside resources in central Jiangsu area; jointly develop industry parks, promote the share of resources and information across the river, and put hands together for development and construction; strengthen the cooperation between the joint cities, and based on the existing and cross-river channel to be completed, overcome the limit of administrative regions and promote the formation of unique economic zones. Build seaports in central Jiangsu area, promote the traffic and infrastructure level, and build an urban space structure of “three pole-one belt-multi joints”. With the main seaport area of Lianyungang Seaport, Yangkou seaport area of Nantong Seaport and Dafeng seaport area of Yancheng Seaport as the focus, promote the construction of Lvsi seaport area of Nantong Seaport, seaport group at Guanhekou area, Sheyang seaport area and Binhai seaport area of Yancheng Seaport at the right moment to support the seacoast urban belt, and make this area the most convenient exit to sea and a window to the outside world along Longhai and Lanxin Railway.

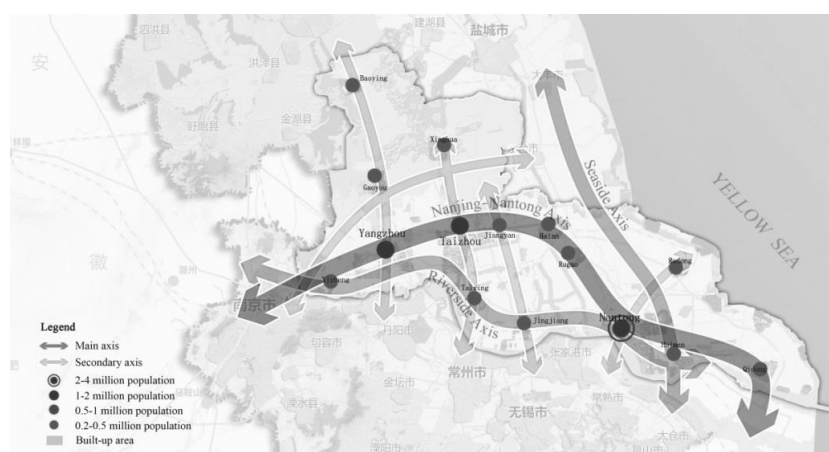

Figure 7. Optimization Measures for Urban Space Form of the Moderately Developed Area.

Cultivate growth pole in north Jiangsu area and construct urban groups with central cities as the core

During the development process of north Jiangsu area, attention should be paid to the cultivation of growth poles. Enhance the development of central cities, and bring the potential advantage into full play. Given the fact that the urban development is still at the cluster stage, we should give priority to the development of major cities and enhance the development of central cities. Actively cultivate central cities like Xuzhou, Huaiyin, Yancheng and Lianyungang and develop counties and central towns to transform the pattern of “ponies drawing cart” into the pattern of “a group of horses drawing cart”.

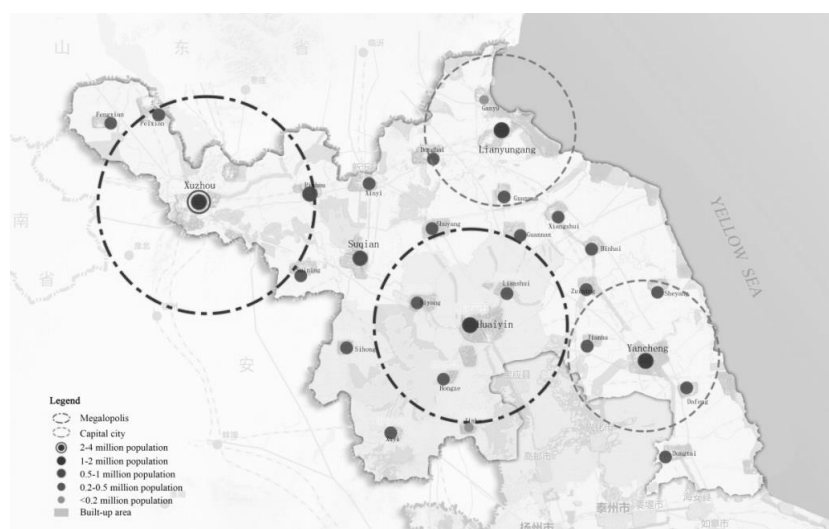

Figure 8. Optimization Measures for Urban Space Form of the Under-developed Area.

Conclusion

The unbalance in provincial economy is a common phenomenon in China. The economic development of the counties (districts) in Jiangsu Province presents a progressive decrease from south to north, with a gradient feature between south, central and north Jiangsu areas.

The urban space form of the areas with different economic development level varies significantly. South Jiangsu area takes a net-like cluster form with Nanjing region and Suzhou-Wuxi-Changzhou region as the dominant; central Jiangsu area takes a belt-like cluster dominated by Nanjing-Nantong traffic axis; and north Jiangsu area takes a point-like cluster dominated by Xuzhou, Huaian, Yancheng and Lianyungang. The new urban belts emerge in south and central Jiangsu riverside area, and central and north Jiangsu seaside area.

The evolution dynamic mechanisms vary greatly in the areas with different economic development levels. The industry structure dominates, the traffic corridor pilots, and science and technology guides urban space structure.

For the areas with different economic development level, different measures should be taken to optimize urban space structure. South Jiangsu area should stress the construction of giant city and promote regional integration; central Jiangsu area should mainly construct riverside and seaside urban development belt to realize integration of south and central Jiangsu areas; and north Jiangsu area should focus on the construction of urban groups with central cities as the core to achieve regional development.

Gilberto Freyre's work: between urban morphology and building typology – first approaches

E-mail: solangedearagao@gmail.com; afrm1979@gmail.com.

Abstract. *There are many possible ways of reading Gilberto Freyre's work. One can read them to know about Brazilian society; other to understand the process of mixing races from which resulted Brazilian people; yet some other can do that to get to know the History of Brazil from a sociological point of view. But there is also another possibility which is to find morphological and typological approaches throughout Freyre's work. Since the sociologist adopted the house as the centre of interest of a great part of his works, and analyzed it to comprehend Brazilian society, there is a lot of information in his texts regarding certain types of buildings, as well as information concerning the cities where these buildings were placed. In fact, Gilberto Freyre was one of the first Brazilian researchers who gave attention to the study of the traditional house in relation to the urban landscape it composed. We aim here to present some morphological and typological approaches in Gilberto Freyre's work, considering the trilogy composed by *The masters and the slaves*, *The mansions and the shanties*, and *Order and Progress*, as well as some other important works in which he deals with the theme of the Brazilian house.*

Key Words: *Gilberto Freyre's work, urban morphology, building typology, the Brazilian house, 19th century.*

Introduction

During the 1930's, Gilberto Freyre published two of his main works: *The masters and the slaves* (1933) and *The mansions and the shanties* (1936). In both of them he adopted the Brazilian house as the centre of interest of his research on Brazilian society. In both of them he mentioned the creation and transformation of Brazilian types of buildings, mainly those destined for habitation, analysing the house produced by a society still in process of formation instead of the house or building projected by renowned architects.

Whereas in *The masters and the slaves* his focus of interest was the rural residence, particularly the sugar-mill complex, in *The mansions and the shanties* he was interested in the urban house – specially the two up to five-storey house which made up some Brazilian urban landscapes at the 19th century. To analyse the house, Freyre considered also the city, or the urban context, with its open and built spaces.

To do this research, Gilberto Freyre made use of some sources such as traveller's writings, biographies, memories, 19th century journals, 19th century photographs and pictures, and some other materials which were not vastly considered by Brazilian historians up to then. Therefore, regarding History and History of Architecture, Freyre's work was innovative in the use of these source materials, as well as in that consideration of the ordinary house which composed the majority of the urban and the cultural landscape.

In his work Gilberto Freyre studied the master's residence and slave habitation, the two-storey house and the "mucambo" (or the shanty), the ground-floor house and the five-storey house, and referred also to the chalet, to the garden small palace, and to the country house. In describing them, comparing them, relating them with landscape, with their surroundings, with society, with ways of living, he built up a typology of the Brazilian house of the 19th and preceding centuries.

Curiously he was not an architect but a sociologist interested in the study of the house for comprehension of society. It is also necessary to mention that previously to the writing of these

works he had the opportunity of studying in the United States and in Europe, where he would make contact with specialists who were worried about cultural aspects not under consideration in Brazil up to then – which meant an important influence on his work and thought.

Always remembered by the everlasting discussion on the advantages of mixed race, Gilberto Freyre should also be considered as one of the predecessors of professionals whose study of the type takes into account society, history and certain morphological aspects. When he came back to Brazil, he was ready to write several studies on the Brazilian house – in spite of his main objective being the study of Brazilian society.

Morphological and typological approaches in Gilberto Freyre's work

While in Europe the first studies of the urban form appeared at the end of the 19th century in works such as those written by Otto Schlüter who established a morphology of the cultural landscape, in Brazil the first studies of the urban form may be attributed to some travellers who visited the country during the 19th century whose analysis is more than merely descriptive. Differently from what happened in Europe, it was not the rapid increase of the cities that caught the attention of these travellers, but rather some lack of development in comparison with European civilisation as well as their peculiarities such as the fact of their being surrounded by tropical vegetation and their geographical aspects – not to mention cultural, social, historical, economical and architectural differences.

Certainly these studies did not compose a disciplinary field as those by Otto Schlüter and other European geographers; besides, they were written and produced by foreigners; however, they do reveal the 19th century Brazilian city in many aspects even if from an European point of view. Land form, climate, particularities of rivers and vegetation, the arrangement of houses and streets, numbers of floors, building materials, squares, public buildings, all of these characteristics of the 19th century Brazilian city can be found in some traveller's writings.

In Europe, Schlüter's influence spread out at the half of the 20th century through Conzen's works (Larkham, 1998). According to this geographer, the urban settlement has the essential attributes of a region and for this reason allows three complementary approaches: the functional, the morphological, and the historical-geographical (Conzen, 2004). In the case of the morphological approach, Conzen emphasizes on the one hand the importance of identification of formative processes and their geographical results in the townscape, and on the other hand the need of close attention to every significant townscape detail (Conzen, 2004).

In Brazil, Conzen's ideas did not spread out until the last decades, but Otto Schlüter has been a renowned geographer in the field of urban geography. Pierre Monbeig and Aroldo de Azevedo were responsible then for introducing, in the 1950's, the analysis of the urban space in Brazil taking into consideration geographical, historical, social, and cultural aspects.

Concerning typology, in Europe the study of the building type dates back to the epoch of the Industrial Revolution when Jacques Nicolas Durand attempted to classify types of buildings which made up the architectural pattern from the period. Philippe Panerai defined Durand's typology as analytical since it revealed but basic schemes of building plans and façades (Panerai, 1999). A typology interconnected with urban morphology that evinced relations between building types, the urban context, and the historical period was established in Europe only in the 1950's, when Saverio Muratori founded the Italian school of typology (Moudon, 1998). In the following decade, during the 1960's, Phillippe Panerai and Jean Castex started to develop a new method of typological analysis creating then the French school of typology (Moudon, 1998).

Whereas in Europe geographers were many times responsible for building typology during the 20th century, in Brazil it was Gilberto Freyre, a sociologist, who brought into light the importance of the study of the type for the understanding of man and society. Afterwards were historians of architecture rather than geographers who dedicated their research to the study of building types.

A considerable difference between building typology in Europe and building typology in Brazil results from this fact. When typology appeared in Brazil it was intrinsically related to social consideration, as well as to the urban and rural context.

In Gilberto Freyre's work social, geographical, and cultural aspects are always interconnected. When he studies and analyses some types of buildings, such as the mansion (or the two or more storey houses) and the *mucambo* (or the shanties), he does it with morphological and typological approaches. He considers house plans, as well as the house in relation to environment, streets, gardens, patios, and the landscape it composes. As a sociologist Freyre was able to establish a typology of the 19th century Brazilian house with a something of the study of the urban form.

If we take into account European or any other international study of the urban form or of building types, the relevance of Gilberto Freyre's work relies exactly on the importance he gave to social aspects in the study of building types as well as on his perception of the role of the house in society and in the shaping of man. Freyre believed that this type of architecture – the house – was one of the most important expressions of a culture. As a sociologist he recognized also the importance of this morphological element in the composition of landscape, specially the cultural landscape.

The Brazilian city in Gilberto Freyre's work

In 1960 the Brazilian geographer Aroldo de Azevedo published a text entitled "Gilberto Freyre's work examined by the light of Geography" (*A obra de Gilberto Freyre examinada à luz da Geografia*). In this text, Azevedo draws attention to the important contribution of Gilberto Freyre's work to the field of Geography in Brazil. Azevedo lists some of the main geographical aspects that can be found in Freyre's work such as certain characteristics of the Brazilian environment, or the process of colonization, as well as some relevant aspects concerning the Brazilian city.

In "The mansions and the shanties" Freyre presents a study of urban life in Brazil in the 19th century which has many times a geographical conotation as it includes information on the placement of Brazilian cities, on their urban characteristics, and on their streets, squares and buildings (Azevedo, 1960).

Recife is defined by Freyre as "socially an island and geographically something between an island and a peninsula" (Freyre, 2006a). Differently from what happened in most 19th century Brazilian cities, in Recife there existed flat streets where it was possible to find some four-storey houses – a consequence of the geographical characteristic of the place, since there was not much space so that houses could be larger than higher (Freyre, 2006a).

Rio de Janeiro was a city marked by its hills, and this geographical characteristic determined from beginning some social differences and spatial segregation in the urban space. According to Freyre, at first the rich built their houses on the top of the hills, while the poor lived at the bottom of them. Afterwards, the rich left the highest parts of the city to live by the sea, while the poor occupied the hills (Freyre, 2006a).

Regarding the city of Salvador, in Bahia, Freyre observes that it has always been characterized by large and extended streets, with houses open to the sea with plenty of palm trees in their yards (Freyre, 2006a). During the 19th century, the urban landscape of Salvador was also marked by gardens between the houses, mainly in the suburbs where the rich would live (Freyre, 2006a) – once again it is possible to find a relationship between the type of building and its geographical location in the work of Gilberto Freyre.

When the sociologist takes into consideration the city of São Paulo, he emphasises how soil type determined building materials during colonial times and in the earlier half of the 19th century, with a predominance of mud walls in urban houses, and how climate influenced architecture as in the use of glass windows instead of windows made of wood, due to the rains (Freyre, 2006a). He also affirms that in São Paulo there was a preference for country houses

surrounded by gardens and fruit trees to the detriment of urban houses – which partially explains the empty aspect of the city related by 19th century travelers (Freyre, 2006a).

The Brazilian city in Gilberto Freyre's work is considered in its morphological (or geographical) aspects, and these aspects are revealed to explain the way the city was structured – with spatial or social segregation –, to be related with some characteristics of the house itself, and to bring to light characteristics of Brazilian society. In Freyre's work everything is interconnected: the Brazilian city, the Brazilian society, and their types of buildings.

Types of buildings studied by Gilberto Freyre

Amongst those houses studied by Gilberto Freyre are the master's residence, slave habitation, the two or more storey houses, the ground floor house, the mucambo (or the shanty), and the chalet.

The first one is described at the preface of "The masters and the slaves": "(...) The sugar-mill master's residence that the colonizator started to build up in Brazil at the 16th century with large mud walls or stone and lime walls, roofed with straw or tiles, a porch in front and beside it, fallen roofs in a maximum of protection against the strongest sun and tropical rain was not a copy of Portuguese houses, but a new expression, corresponding to our phisic environment and to an unexpected phase of Portuguese imperialism: their agrarian and sedentary activity in the tropics, their rural and proslavery patriarchy. Since this time the Portuguese (...) became Lusitanian and Brazilian at once, the founder of a new economic and social order; the creator of a new type of habitation. It is enough to compare the floor plan of a 16th century Brazilian house with a 15th century Lusitanian manor-house to find out the enormous difference between the Portuguese from the reign and the Portuguese from Brazil." (Freyre, 2006b)

The sugar-mill master's residence was a symbol of power in rural areas. Not only slaves but also children and women were under domination of the master inside the limits of his property.

The first master's residences were simple to the point of being roofed with straw. However, throughout the centuries this type of building became more solid being built with less ephemeral materials. Palm trees started then to mark the front garden and the landscape, symbolising the nobleness of the house and the power of its owner. The patio garden was a mixture of the vegetable garden and the orchard, and presented a meaning of utility much stronger than an aesthetic value, as Gilberto Freyre observed in his second work (Freyre, 2006a).

Inside the master's residence one could find only the strictly necessary mobiliary; certain rooms would even appear predominantly empty to the European eye at the beginning of the 19th century. Some chairs here and there, sometimes a table, some other wooden mobiliary, and it was all that one could find there. Women would sleep in alcoves – bedrooms without windows – away from the eyes of the stranger and under the eye of the master.

The floor plan of the master's residence could be characterised sometimes by a porch between the guest's room and the oratory, a living room after the porch with bedrooms and alcoves on the left and on the right, and a kitchen at the back of the building close to the patio.

The master's residence was part of a complex in rural areas which included slave habitation. This was even more rustic than the former. In general, it was a rectangular building with mud walls, roofed with straw or tiles, with small openings, where slaves would sleep. Floor tiles were not used; instead the ground floor was made of soil. This type of building was in fact a large and rustic room for slaves.

While the master's residence – together with slave habitation – was placed in rural areas, the two or more storey houses were situated in the city. They were the richest type of urban house during the colonial period. As Gilberto Freyre emphasised, the number of floors as well as building materials were different from place to place. In São Paulo, this type of building used to have two storeys and was built with mud walls; in Salvador, Recife and Rio de Janeiro, they were made up of stone or brick and could have three, four or even five storeys (Freyre, 2006a).

The ground floor of such houses would commonly have rooms for slaves and guests, a store or warehouse, and a narrow corridor which led to the patio. The owner's family would live in fact on the upper floors, where there were rooms and alcoves. Kitchens used to be in the attic, where there were also rooms for female slaves. This kind of arrangement became so usual in the Brazilian house that Vauthier would affirm at the 19th century that those who had seen one of them had seen all of them (Vauthier, 1975).

The two or more storey houses were owned by some of the richest people of Brazilian society (from aristocracy and bourgeoisie), and symbolised the most civilised type of habitation in the tropics, according to Freyre: "There were not a few Brazilians from the first half of the 19th century to whom the good people, the good couple, the family well established, according to the patriarchal orthodoxy, should live, in the city, in a two or more storey house, leaving the ground floor house of any sort for those who were socially less consolidated. (...) This conception – of the two storey house still patriarchal and already bourgeois representing the best and highest Brazilian civilisation, at the end of the 18th century and at the beginning of the 19th century – seems to have been general amongst the cultured men of this epoch. Not only Brazilians would have it but also Europeans from the North – almost all of them impregnated with bourgeois and urban notions of civilisation." (Freyre, 2006a)

These houses were built side by side on the alignment of narrow lots without front yards (Reis Filho, 1970). Sometimes painted yellow or some other vivid colour, they made up some Brazilian urban landscapes up to the 19th century. But in between one and another building there would almost always be a ground floor house. This was simpler and poorer than the two or more storey house. It used to have a store or room at the entrance, followed by one or two alcoves, and a kind of dinning room with a kitchen at the back. Many times it would not present a tiled floor – which would contribute to a great extent to give it a dirty appearance. But however plain was it, this type of building would compose the Brazilian landscape in the same way as the two or more storey houses, built up on the alignment of narrow lots. One could say that it was even commoner than the former, mainly within those cities far away from the coast, where European influence was not so deep and commerce was less developed.

Narrow houses built on narrow lots on irregular blocks alongside narrow streets – this was the Brazilian urban morphological pattern during colonial times.

Near the city and sometimes inside of it there was the "mucambo" – one of the poorest types of habitation, but not the worst one concerning some ecological aspects according to Gilberto Freyre (2006a). The "mucambo" was a ground floor house made of straw and stick, and covered with palm leaves, in which it was clear the native and African influence. It was situated in mud flats or in swampy areas – the less valuable areas near the city. The internal arrangement was similar to that of the urban ground floor house, but instead of alcoves, it had bedrooms with windows.

Notwithstanding quality of materials used in this type of building or even the fact of its being an ephemeral house, the "mucambo" was in perfect harmony with the environment. In this sense, it was an ecological type of building.

In "The mansions and the shanties", Gilberto Freyre considered also the chalet, as one of the results of European influence on Brazilian architecture at the 19th century. Whereas in Europe the chalet was a wooden house which could be found in mountainous areas, in Brazil it became a mere style of some urban houses made of brick, characterised by front eaves in contrast with lateral eaves of traditional houses. This type of building used to have a small garden in the front yard – another European influence taking into account that during the colonial period the garden was situated in the backyard or in a patio surrounded by the walls of the residence.

The chalet was also considered in "Order and progress" (1959), in which the sociologist, based on a speech given by Vieira Souto, would express the necessity of a Brazilian architecture to replace certain foreign buildings such as the chalet that spread throughout Brazilian cities at the end of the 19th century and became common even in commercial streets (Freyre, 2004).

In his work, Gilberto Freyre wrote also on the country house, the villas (or small palaces), and the slum tenement. The country house was the best type of residence half way long the city and

rural areas or in the suburbs. It had the advantage of being situated near the city and as well the advantage of being surrounded by nature as the rural residence. Many travellers would emphasise the qualities of the country house and its surroundings such as Robert Burford and W. M. Gore Ouseley:

“(...) The houses in the suburbs are large, more convenient, and abound in the comforts of Europe: they are generally in large gardens, which during a great part of the year resemble huge bouquets (...)” (Burford, 1827)

“The Laranjeiras road is one of those that lead to the ascent of the Corcovado. It follows the winding course of a mountain brook, and the scenery is varied and beautiful. On either side are country houses, cottages, gardens, and ‘chacras’ or villas, in their enclosed grounds.” (Ouseley, 1852)

To the European eye the country house was a better place for someone to live in than the two storey house within the city. Surrounded by gardens, with a large porch, and many fruit trees throughout its terrain, such ground floor house with oratory, living room, bedrooms and alcoves, and a kitchen at the back, would seem to Europeans more advantageous in aesthetic and hygienic terms than the urban narrow two storey house.

The villas or small palaces in the same way as the chalet would be the result of European influence at the end of the 19th century as well as an expression of Eclecticism. According to Freyre the small palace was many times the residence of the “new-rich”, the “new-powers”, the “new-intellectual” (Freyre, 2004). It was another type of European building transferred to Brazil, where the social, cultural, and environmental context was totally diverse. But little by little it became one of the urban ways of living of aristocracy and bourgeoisie. Maria Cecília Naclério Homem has defined the small palace as the “type of one-family house, with one or more storeys, cellar, stylistic accuracy; a detached house, surrounded by gardens, with a service area and an annexe at the back” (Homem, 1996).

Inside the residence, as well as outside it, the small palace or villa would express a clear European influence on architecture. Sometimes neoclassical, other times eclectic, its rooms, its mobiliary, its architectural aesthetics would demonstrate that obsession with everything which was European. Above all, the urban small palace or villa, with its vast garden, would be a symbol of status as the master’s residence in rural areas.

While the small palace became the richest type of urban residence, the slum tenement became the poorest one. Carlos Lemos affirmed that the slum tenement was not a house in fact but a group of very small rooms where all the activities would be developed at the same place (Lemos, 1998). The slum tenement was characterised by the worst building materials and by a bathroom and service area common to all residents. It was not a healthy type of building but it was preferred to the “mucambo” by immigrants, and for this reason it became habitation for many industry workers (Freyre, 2006a).

In “The masters and the slaves”, “The mansions and the shanties”, “Order and progress”, and some other books, Gilberto Freyre brought to light relevant information on the Brazilian house. However, it was in “The mansions and the shanties” that he decidedly presented a typological study. In this book, he compared the two storey urban house with the “mucambo”, with the ground floor house, with the country house. He emphasised differences between two storey houses from one city to another. He established a relationship between the house and the street and analysed their transformation at the 19th century under European influence. He established a relationship between the house (or types of houses) and the 19th century Brazilian society – under European influence. He considered the “mucambo” within the environment it was part of. He established hierarchies and gave attention to materials, to room arrangements, to open and built spaces. In these terms, it is possible to affirm that he introduced the study of the type in Brazil, more specifically the study of the building type with some morphological connotation, at the moment he wrote and published his second work.

In Gilberto Freyre’s work it is possible to find some information on the Brazilian city and some information on the Brazilian house, but not only this. Freyre’s analysis of the Brazilian house as well as of the Brazilian city reveals some typological and morphological approaches

with a sociological refinement which is nowadays indispensable for any typological or morphological study.

The read of European and American texts was fundamental to his consciousness of the importance of the house in man's life, in society, in the urban or the rural landscape. As a sociologist he looked at the house to understand man and society, but the cultural inheritance from his work goes beyond this. The richness of his work lies not only in the comprehension of Brazilian society, but also in the knowledge of Brazilian houses, Brazilian gardens, Brazilian landscapes. His contribution goes far beyond the sociological field and reaches history of architecture, history, geography, landscape architecture, and so on. His work is certainly of great significance to Brazilian people but also to those who are interested in the way the sociologist analyses the house considering landscape and society.

The purpose of this paper is to present the results from research conducted in the years 2011-2013, entitled: "Meeting of Minds", which investigated the common concepts and different approaches of the two major schools in urban morphology. The research focused on the survey work undertaken by the founders of the schools in order to carry out an urban analysis in England and Italy and thus establish, as well as, compare and contrast their different methods. Other sources of documentary references were found in books, publications in academic journals, together with, the reports of pupils who participated in the formation of these methods. Examples of convergence can be found in these approaches. Both, for example, consider the form as a product constructed throughout time and thus take the view that research should concern itself with the investigation of the transformations and continuities of the form in the urban landscape. However, the methods differ with regards to the scale of analysis. The English school tends to examine the form from the general to the particular, while in contrast, the Italian school chooses to take the building as the starting point and widens its focus to include the whole territory. In this sense, the concepts adopted by schools show both similarities and differences, however both reflect the specific goals of each approach. For the English school, the geographical approach is the guideline for a tripartite division of urban form. Conversely, for the Italian school, the architectural approach represents many focuses in relation to the basic built type and the typological process that transforms it over time. It is a primary contention of this article that the knowledge acquired from the structure of both schools may contribute to the development of a wider interdisciplinary approach to research on contemporary cities.

Key Words: schools of urban morphology; research; approaches; similarities; differences.

Meeting of Minds: Investigation on the common concepts and different approaches of the major schools of urban morphology
